PUZZLING REFLECTIONS

TEXTBOOKS SUPPLEMENT

Why this new preparative method delivers pure protein and even peptide hormones

Well to begin with, you won't compromise high sample load with poor resolution. In fact, our way gives you 10 times greater load and also 10 times better resolution – at the same time!

Sounds too good? Just try advanced electrofocusing by using Immobiline. It's the only system available that lets you immobilize the pH gradient within the gel, puts an end to drift, cuts out conductivity gaps and gives you infinite stability.

Look up J. Biochem. Biophys Methods 8 (1983) 157–172, and find out how preparative electrofocusing separates proteins in quantities of up to 1 gram – completely free from low molecular weight contaminants. Better still, just fill in the coupon and get all the facts. Or try it straight away, and I'll see that we give you an attractive discount on your first order.

- ☐ Please send me your new brochure on The Immobiline System for analytical and preparative electrofocusing.
- ☐ Please send me your latest catalogue on Quality Chemicals for electrophoresis and electrofocusing.
- ☐ Please call me.

Hypertension and blood pressure research

^{125}I-labelled atrial peptides

Amersham's ^{125}I-labelled rat ANP (28-residue sequence) in tissue autoradiography of guinea pig kidney and adrenal. Photographs kindly supplied by Dr P W Mantyh, Center for Ulcer Research and Education, UCLA, USA.

Labelled peptides

- (3-[^{125}I]*iodotyrosyl*^{28})**Rat atrial natriuretic peptide**
(28-residue sequence) IM.186
- (3-[^{125}I]*iodotyrosyl*^{28})**Human α-atrial natriuretic peptide** IM.187

These ligands are supplied at a specific activity of ~2000Ci/mmol, ~74TBq/mmol.

Tracer and antiserum for RIA

- This reagent pack, IM.1871, contains a rabbit antiserum to human α-ANP which cross-reacts totally with the corresponding rat sequence and [^{125}I]human ANP. Sufficient for 250 assay tubes using the protocol provided.

Related compounds

- Galactic H_2O maser
- Early therian mammal

GUIDE TO AUTHORS

Authors should be aware of the diversity of *Nature*'s readership and should strive to be as widely understood as possible.

Review articles should be accessible to the whole readership. Most are commissioned, but unsolicited reviews are welcome (in which case prior consultation with the office is desirable).

Scientific articles are research reports whose conclusions are of general interest or which represent substantial advances of understanding. The text should not exceed 3,000 words and six displayed items (figures plus tables). The article should include an italic heading of about 50 words.

Letters to *Nature* are ordinarily 1,000 words long with no more than four displayed items. The first paragraph (not exceeding 150 words) should say what the letter is about, why the study it reports was undertaken and what the conclusions are.

Matters arising are brief comments (up to 500 words) on articles and letters recently published in *Nature*. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted.

Manuscripts may be submitted either to London or Washington (decisions being made only in London). Manuscripts should be typed (double spacing) on one side of the paper only. Three copies are required, each accompanied by copies of lettered artwork. No title should exceed 80 characters in length. Reference lists, figure legends, etc. should be on separate sheets, all of which should be numbered. Abbreviations, symbols, units, etc. should be identified on one copy of the manuscript at their first appearance.

References should appear sequentially indicated by superscripts in the text and should be abbreviated according to the *World List of Scientific Periodicals*, fourth edition (Butterworth 1963-65). The first and last page numbers of each reference should be cited. References to books should clearly indicate the publisher and the date and place of publication. Unpublished articles should not be formally referred to unless accepted or submitted for publication, but may be mentioned in the text.

Each piece of artwork should be clearly marked with the author's name and the figure number. Original artwork should be unlettered. Suggestions for cover illustrations are welcome. Original artwork (and one copy of the manuscript) will be returned when manuscripts cannot be published.

Requests for permission to reproduce material from Nature *should be accompanied by a self-addressed (and, in the case of the United Kingdom and United States, stamped) envelope.*

FPLC from goes beyond HPLC

The pace of today's biological research allows no compromise in the performance of your separation tools. No compromise in performance means instruments and separation media designed and optimized specifically for biomolecules. The Pharmacia FPLC System stands alone as the original high performance liquid chromatography system designed for the special needs for such applications as:

- Enzyme purification
- Peptide mapping
- Analytical protein separations
- Purification of biologically active peptides
- Separation of polynucleotides

FPLC is a unique approach, designed to eliminate the incompatibilities of traditional HPLC technology. For the last 20 years, traditional HPLC pump design, high pressure columns and stainless steel wetted surfaces were developed to solve problems different from the ones you have today.

Why "make-do" with compromise using old HPLC technology when FPLC has proven itself with such difficult samples as monoclonal antibodies, restriction enzymes, blood, urine and viral proteins?

After 25 years of experience in developing basic separation methods like gel filtration, affinity chromatography and chromatofocusing, we at Pharmacia can tell you that FPLC incorporates some of the most significant discoveries in separation chemistry since the introduction of Sephadex®.

FPLC respects the origins of the biomolecule and achieves unprecedented speed, resolution and recovery.

NATURE VOL. 314 14 MARCH 1985

COVER

FRACTAL VISCOUS FINGERS

When a less viscous fluid like water pushes a more viscous fluid like oil, an instability phenomenon occurs, the 'viscous finger instability', so called because the water forms 'fingers' as it penetrates the oil. It now appears that under certain conditions these highly ramified and irregular patterns are fractals, and can be quantitatively characterized by a number termed the fractal dimensionality (see p.141).

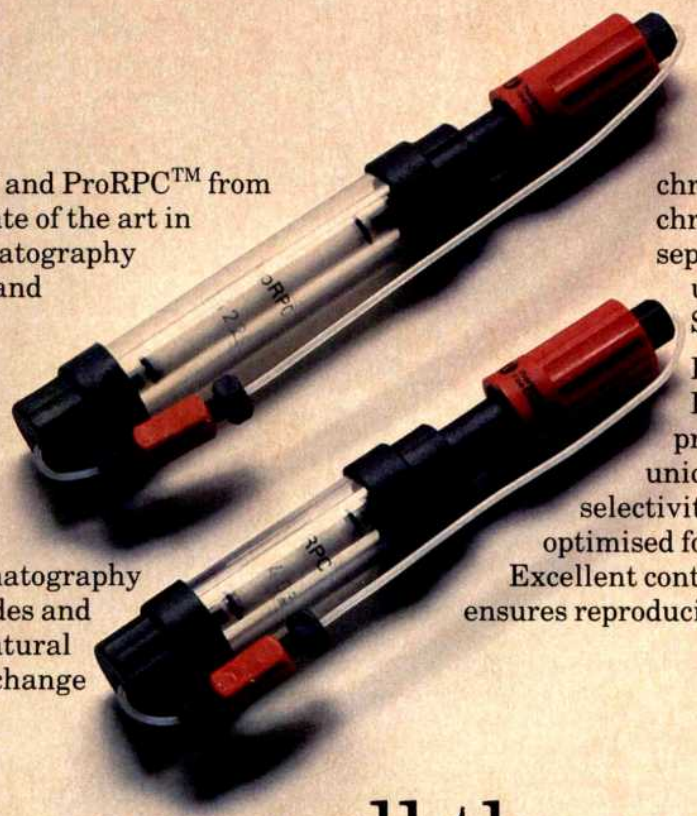
Authors should be aware of the diversity of *Nature*'s readership and should strive to be as widely understood as possible.

Review articles should be accessible to the whole readership. Most are commissioned, but unsolicited reviews are welcome (in which case prior consultation with the office is desirable).

Scientific articles are research reports whose conclusions are of general interest or which represent substantial advances of understanding. The text should not exceed 3,000 words and six displayed items (figures plus tables). The article should include an italic heading of about 50 words.

Letters to *Nature* are ordinarily 1,000 words long with no more than four displayed items. The first paragraph (not exceeding 150 words) should say what the letter is about, why the study it reports was undertaken and what the conclusions are.



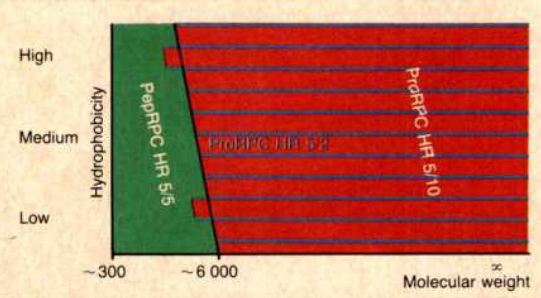
Matters arising are brief comments (up to 500 words) on articles and letters recently published in *Nature*. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted.

Manuscripts may be submitted either to London or Washington (decisions being made only in London). Manuscripts should be typed (double spacing) on one side of the paper only. Three copies are required, each accompanied by copies of lettered artwork. No title should exceed 80 characters in length. Reference lists, figure legends, etc. should be on separate sheets, all of which should be numbered. Abbreviations, symbols, units, etc. should be identified on one copy of the manuscript at their first appearance.

References should appear sequentially indicated by superscripts in the text and should be abbreviated according to the *World List of Scientific Periodicals*, fourth edition (Butterworth 1963-65). The first and last page numbers of each reference should be cited. References to books should clearly indicate the publisher and the date and place of publication. Unpublished articles should not be formally referred to unless accepted or submitted for publication, but may be mentioned in the text.

Each piece of artwork should be clearly marked with the author's name and the figure number. Original artwork should be unlettered. Suggestions for cover illustrations are welcome. Original artwork (and one copy of the manuscript) will be returned when manuscripts cannot be published.

If you have to say FPLC you are half way there ...



... because PepRPC™ and ProRPC™ from Pharmacia are the state of the art in reversed phase chromatography media for separating and recovering biological molecules.

Pharmacia reversed phase chromatography columns have been specially designed for high resolution chromatography of peptides, polypeptides and proteins, forming a natural complement to ion exchange chromatography and chromatofocusing when separating biomolecules using the Pharmacia FPLC System.

Pharmacia media PepRPC and ProRPC provide you with new and unique reversed phase selectivities (C_2/C_{18} and C_1/C_8) optimised for peptides and proteins. Excellent control over the new synthesis ensures reproducibility from batch to batch.

... so go all the way.

The Pharmacia RPC media are prepacked in boro-silicate glass columns with optimised lengths to utilize a range of reversed phase separation techniques for high resolution and high recoveries of both large and small polypeptides.

- Controlled synthesis for batch to batch reproducibility
- High recoveries of peptides and polypeptides
- High resolution of hydrophobic fragments
- Optimised bonded phase composition

FPLC from Pharmacia goes beyond HPLC with biocompatibility,

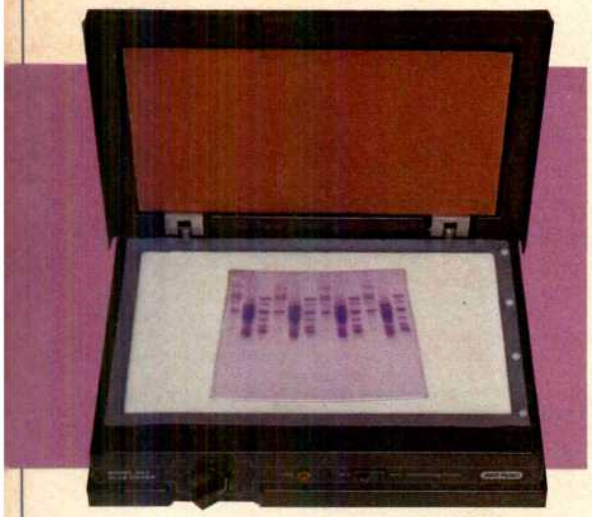
The new Bio-Rad PROTEAN™ II system

Here's Bio-Rad's entirely new Protean II system for SDS-Page, 2D electrophoresis, and other vertical techniques. No other system comes close to offering you such rapid setup, simple operation, and excellent resolution.



The PROTEAN II Cell— heart of the system.

- Unprecedented ease of assembly and casting.
- "Smile-free" patterns with only 1.5 liters of buffer.
- Easy sample loading, even 2D.
- Accommodates 16 x 16 cm or 16 x 20 cm slabs.
- Tube adaptor for complete 2D in one cell.
- Four slab capacity to separate up to 100 samples per run.
- Bottom gradient filling capability.

Run up to 25 samples per gel
Excellent accessibility means you can easily load and run 25 samples without lateral diffusion.

New slab dryer eliminates cracking

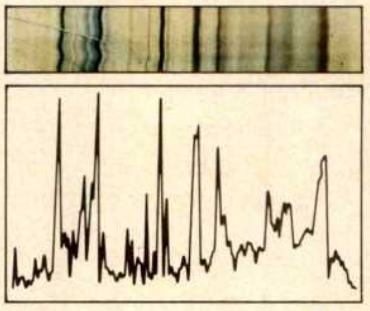
- Crack-free drying independent of gel thickness and composition.
- Transparent gasket lets you see gels during drying without breaking the vacuum seal.
- Soft IEF gels, high percent acrylamide, even steep gradients, dry without band spreading or cracking.
- Dryers in two sizes; 18x34cm and 35x45 cm drying surface.

A 5 to 30% gradient gel dried in 3 hours at 80°C without cracking.

dvanced system aration and analysis

Trans-Blot® Cell— high intensity electrophoretic transfer

- Adjustable electrodes for optional high field intensity transfers.
- Optional super cooling coil for high power applications.
- Removable platinum electrodes for easy cleaning.



High field intensity transfer of myosin (mw: 200,000).

State-of-the-art video densitometer

- Totally digital instrument scans in transmission or reflection with no moving parts.
- Powerful 16-bit microprocessor.
- Menu-driven, mouse controlled system.
- 27 functions, including baseline subtraction, filtering and enhancement, to optimize the measurement, display, and output of data.
- Programmable up to 250 steps
- Zoom-in, measure integrals and mobilities directly on screen.
- Analog and RS-232 ports, and a choice of output options.

Comprehensive technical support

Bio-Rad backs you with in-depth applications information, step-by-step protocols, and detailed technical bulletins. As always, our technical staff is ready to help. Just call.

The Essence.

How can a busy researcher sort out the staggering amount of information published each year on chromatography, electrophoresis, immunochemistry and HPLC? One good way is to make sure you have this year's Bio-Rad catalog. It contains the essence of what's new and important in materials, equipment and systems for these important techniques. And includes detailed application data to help you use these techniques successfully.

Our annual catalog is but one of many useful tools and services Bio-Rad offers in support of the research chemist. We maintain an extensive library of technical bulletins, application notes, and practical, step-by-step manuals. Seminars, technical papers and our popular Bio-Radiations journal also help keep you current. Problems? Our Technical Staff is always ready to answer your questions about products and protocols.

In short, you're not just buying our products, you're buying 35 years of expertise.

Remember, a lot happens in a year. Circle the appropriate reader service numbers below for your free copy of this year's Bio-Rad catalog, a subscription to Bio-Radiations, our Protean™II vertical electrophoresis system brochure, and a wealth of data on products and techniques for monoclonal antibodies.

IMPOSSIBLE ANTIBODIES?

DESIGN OSCAR REUTERSVÄRD

Yes, impossible antibodies are for sale, antibodies that do not measure up to your requirements.

As scientists ourselves, we have suffered the agonies caused by such non-specific, impure, low-titer antibodies and therefore we decided to do something about it.

The result is MIAB—a new company on the antibody market — but with vast experience in high quality antibody production. So, now our know-how and experience can help you in your research as well. And nobody has ever regretted quality. A quality so superior that competitors will try to copy us.

Not only do we aim at supplying you with the best antibodies available. We also want to stimulate and enrich your environment by making available to you this fascinating picture of the impossible antibody in "perspective Japonaise".

Fill in the coupon and we will send you more information.

Sometimes things only seem impossible!

MIAB ANTIBODIES
THE TRACER QUALITY ANTIBODIES
FOR THE DEMANDING SCIENTIST.

GUIDE TO AUTHORS

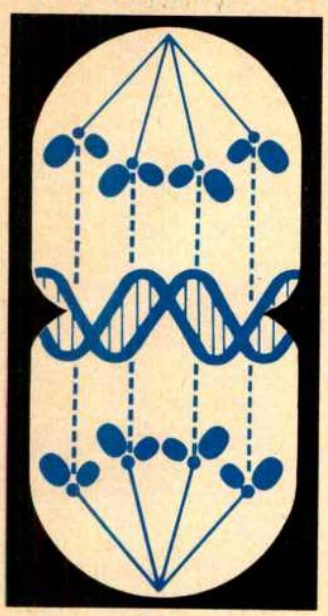
Authors should be aware of the diversity of *Nature*'s readership and should strive to be as widely understood as possible.

Review articles should be accessible to the whole readership. Most are commissioned, but unsolicited reviews are welcome (in which case prior consultation with the office is desirable).

Scientific articles are research reports whose conclusions are of general interest or which represent substantial advances of understanding. The text should not exceed 3,000 words and six displayed items (figures plus tables). The article should include an italic heading of about 50 words.

Letters to *Nature* are ordinarily 1,000 words long with no more than four displayed items. The first paragraph (not exceeding 150 words) should say what the letter is about, why the study it reports was undertaken and what the conclusions are.

Matters arising are brief comments (up to 500 words) on articles and letters recently published in *Nature*. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted.



Manuscripts may be submitted either to London or Washington (decisions being made only in London). Manuscripts should be typed (double spacing) on one side of the paper only. Three copies are required, each accompanied by copies of lettered artwork. No title should exceed 80 characters in length. Reference lists, figure legends, etc. should be on separate sheets, all of which should be numbered. Abbreviations, symbols, units, etc. should be identified on one copy of the manuscript at their first appearance.

References should appear sequentially indicated by superscripts in the text and should be abbreviated according to the *World List of Scientific Periodicals*, fourth edition (Butterworth 1963-65). The first and last page numbers of each reference should be cited. References to books should clearly indicate the publisher and the date and place of publication. Unpublished articles should not be formally referred to unless accepted or submitted for publication, but may be mentioned in the text.

Each piece of artwork should be clearly marked with the author's name and the figure number. Original artwork should be unlettered. Suggestions for cover illustrations are welcome. Original artwork (and one copy of the manuscript) will be returned when manuscripts cannot be published.

NATURE's Fifth International Conference and Exhibition

nature

UPDATE IN MOLECULAR BIOLOGY 1985

Genes and Systems in Development

Presented in association with the University of California at San Francisco

OCTOBER 7, 8, 9, 1985 SHERATON-PALACE HOTEL, SAN FRANCISCO

PERHAPS THE MOST IMPORTANT CONFERENCE YOU'LL ATTEND THIS YEAR!
Featuring preeminent scientists on the frontiers of uncovering new genetic techniques that will aid in understanding the development of micro- and macro-organisms.

NATURE's conference will keep you abreast of the very latest discoveries in . . .

- the diagnosis and therapy of genetic defects
- oncogenes
- homoeotic genes
- yeast development
- the immune system
- the development of neural systems.

CMEs WILL BE AWARDED!

ATTEND OUR GALA CONFERENCE DINNER on Tuesday, October 8, in the historic, glass-domed Garden Court. Admission only $29.50 per person.

POSTER SESSIONS will be held each day. For consideration, please send working title and brief synopsis to Posters Editor, Nature Publishing Company, 65 Bleecker Street, New York, NY 10012.

MEET SPEAKERS AT ROUNDTABLE DISCUSSIONS HELD EACH AFTERNOON and have ample opportunity to present your own ideas.

ROOM RESERVATIONS: Rooms can be reserved directly with the Sheraton-Palace Hotel by calling 800-325-3535. Please mention your participation in the Nature 1985 Conference to qualify for special rates.

BURSARY PROGRAM for selected graduate students to be announced during August 1985.

YOUR REGISTRATION FEE could be tax deductible!

A MAJOR EXHIBITION of scientific products and services will be held in conjunction with the conference.

PROGRAM SCHEDULE*

DAY 1: MONDAY, OCTOBER 7

SYSTEMS

Speakers	*Topics*
F. Bloom (Research Institute of Scripps Clinic)	Vertebrate neural systems
J. Gerhart (U. of California at Berkeley)	Early development—Xenopus
C. Nüsslein-Volhard (Tübingen)	Early development—*Drosophila*
C. Goodman (Stanford)	Development of invertebrate neural systems
H.R. Horvitz (MIT)	Caenorhabditis

DAY 2: TUESDAY, OCTOBER 8

CELLS

Speakers	*Topics*
M. Davis (Stanford)	T-cell receptors
U. Storb (U. of Washington at Seattle)	B cells
J.M. Bishop (U. of California at San Francisco)	Oncogenes
M. Ptashne (Harvard)	Bacterial development
I. Herskowitz (U. of California at San Francisco)	Yeast development

DAY 3: WEDNESDAY, OCTOBER 9

GENES

Speakers	*Topics*
R. Palmiter (U. of Washington at Seattle)	Transgenic mice
D. Hogness (Stanford)	*Drosophila* homoeotic genes
W. McGinnis (Yale)	Mammalian homoeotic genes
T. Friedmann (U. of California at San Diego	Human therapy
Y.W. Kan (U. of California at San Francisco)	Haemoglobinopathies

*Additional speakers will also appear on the program.

TO REGISTER FOR THE CONFERENCE NAT.

Return this form with your check, credit card authorization or an authorized purchase order to: Nature Update in Molecular Biology, Nature Publishing Company, 65 Bleecker Street, N.Y., N.Y. 10012.

Please reserve _____ conference registration(s) and _____ seats at the Tuesday Conference Dinner.

FULL 3-DAY REGISTRATION FEE: $375.00

PAY ONLY $325.00 IF YOU REGISTER BEFORE JULY 31.

nature

NATURE VOL. 314 4 APRIL 1985

COVER

Two superstrings meet and coalesce to form a single superstring. This is the single, fundamental interaction in the theory of the "heterotic" string, one of a small number of related supersymmetric string theories. These models unite particles and forces — including gravity — in what is almost a "theory of everything". (See p.409). Cosmological consequences of superstrings are described on p.415.

Seen in all the best scientific circles

Pharmacia's new Molecular Biology Division has been formed by linking the established strengths of Pharmacia P-L Biochemicals with the separations expertise of Pharmacia Fine Chemicals, creating a group with an unequalled technology base.

This group is dedicated to providing molecular biologists with the tools and advice they need in their research.

Whether you are constructing your own plasmids, sequencing, or working with cDNA, we have the products and the fast delivery that you need.

Everything from nucleotides to separation products and enzymes to expression vectors, are available from one dependable supplier.

Look at our new catalogue and you will see just how much we have to offer.

Write or call us today for your free copy.

You'll be in good company.

Pharmacia... your partner in molecular biology.

This is the sign you can see at 98 airports throughout Europe, Africa, the Middle and Far East, North and South America. Always on the most advanced types of aircraft. For we not only have a high reputation with our passengers (once again we have been voted "Best airline worldwide" by the readers of Business Traveller) but also with the planemakers.

For example the DC-9-81, introduced into airline service by Swissair, was specially designed so we can offer more room on our European flights. On the Boeing 747-357 we initiated the installation of much sophisticated technology as well as more economical and environmentally friendly engines. The Airbus A310 was only acceptable to us when its cargo compartment would take up to 7 tons and other special requirements from cockpit to tail assembly had been met. We converted part of our DC-10 fleet into DC-10 ERs so that the extended range saves our passengers intermediate stops. We were the first airline to order 8 new Fokker F-100s for our European flights - these are even quieter than the jets in use today and when delivered will mean that all Swissair aircraft will be equipped for landing in extremely poor visibility.

At Swissair new aircraft are constantly being replaced by even newer ones.

The sign of Swissair is indeed a sign of the times.

NATURE VOL. 314 18 APRIL 1985

COVER

An Ancient Egyptian mummy-case from the British Museum, dated at around 200 BC and thought to contain the mummified corpse of a priest of Amun. Tissue from such corpses can be a source of DNA amenable to analysis by modern molecular genetic techniques. On page 644 of this issue the sequence of a fragment of DNA from a 2,400-year-old mummy is reported, and this work is discussed on page 576. (Photos: Ronald Sheriden, Hannu Ukkonen)

Amersham – serving molecular biology

We offer an extensive range of products for life science research at the molecular level. And we supply them to just about every leading molecular biology laboratory in the world. Our range is continually being extended and includes:

- Restriction endonucleases
- Modifying enzymes
- Cloning vectors
- M13 cloning and sequencing systems
- λ *in vitro* packaging systems
- Oligonucleotides
- DNA labelling systems
- Labelled nucleotides
- Labelled amino acids
- Protein translation accessories
- Immunological reagents

Our new molecular biology catalogue not only provides a comprehensive guide to this range of products but is also designed to serve as a standard laboratory reference. Ask for your copy now!

Unparalleled commitment to your research

GUIDE TO AUTHORS

Authors should be aware of the diversity of *Nature*'s readership and should strive to be as widely understood as possible.

Review articles should be accessible to the whole readership. Most are commissioned, but unsolicited reviews are welcome (in which case prior consultation with the office is desirable).

Scientific articles are research reports whose conclusions are of general interest or which represent substantial advances of understanding. The text should not exceed 3,000 words and six displayed items (figures plus tables). The article should include an italic heading of about 50 words.

Letters to *Nature* are ordinarily 1,000 words long with no more than four displayed items. The first paragraph (not exceeding 150 words) should say what the letter is about, why the study it reports was undertaken and what the conclusions are.

Matters arising are brief comments (up to 500 words) on articles and letters recently published in *Nature*. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted.

Manuscripts may be submitted either to London or Washington (decisions being made only in London). Manuscripts should be typed (double spacing) on one side of the paper only. Three copies are required, each accompanied by copies of lettered artwork. No title should exceed 80 characters in length. Reference lists, figure legends, etc. should be on separate sheets, all of which should be numbered. Abbreviations, symbols, units, etc. should be identified on one copy of the manuscript at their first appearance.

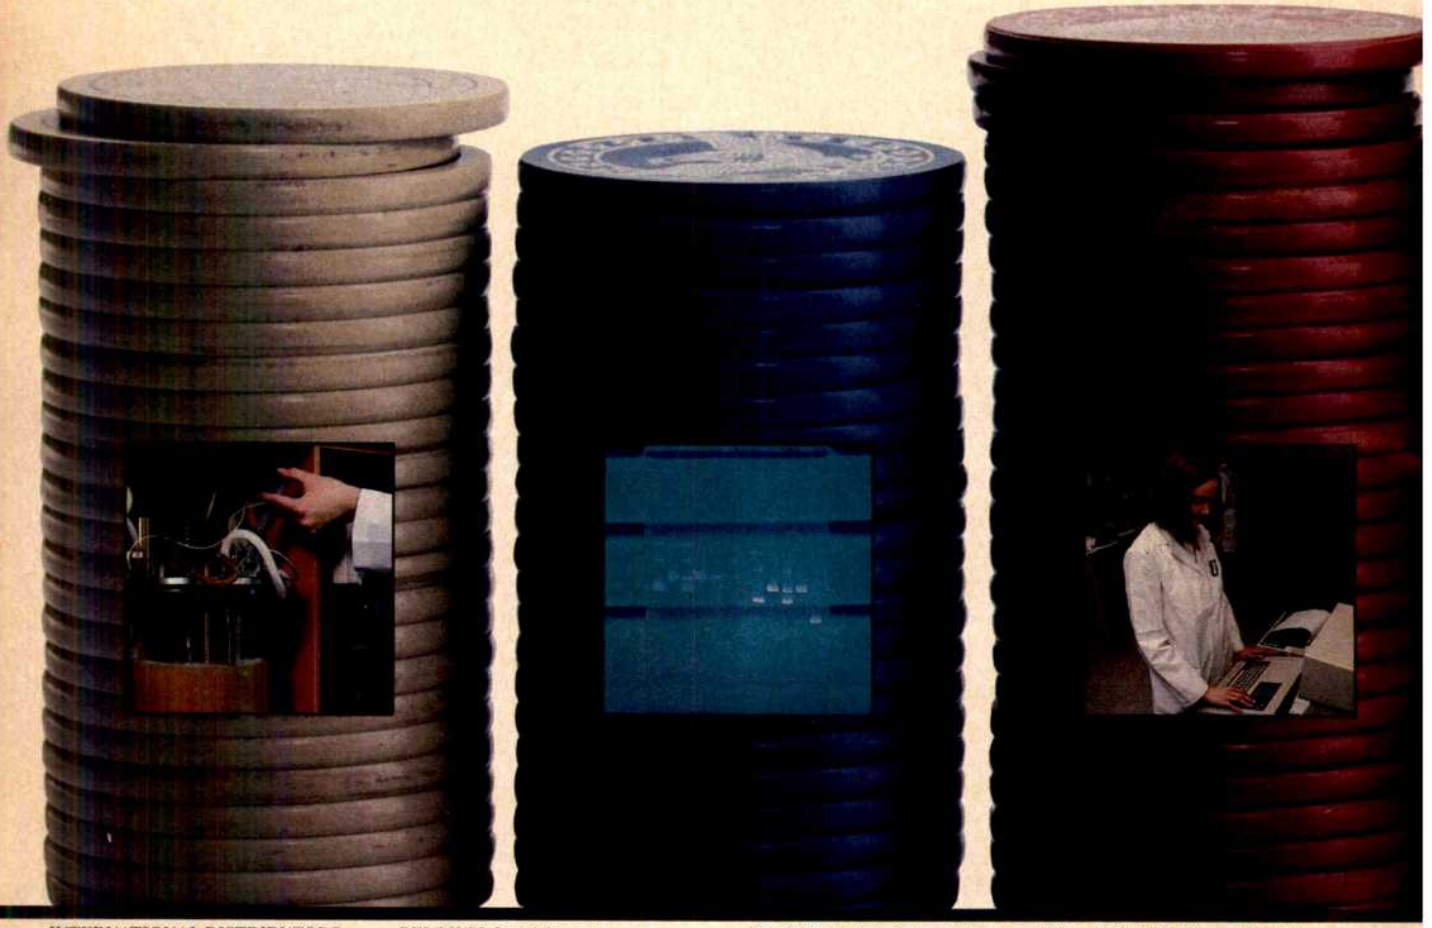
References should appear sequentially indicated by superscripts in the text and should be abbreviated according to the *World List of Scientific Periodicals*, fourth edition (Butterworth 1963-65). The first and last page numbers of each reference should be cited. References to books should clearly indicate the publisher and the date and place of publication. Unpublished articles should not be formally referred to unless accepted or submitted for publication, but may be mentioned in the text.

Each piece of artwork should be clearly marked with the author's name and the figure number. Original artwork should be unlettered. Suggestions for cover illustrations are welcome. Original artwork (and one copy of the manuscript) will be returned when manuscripts cannot be published.

Requests for permission to reproduce material from Nature *should be accompanied by a self-addressed (and, in the case of the United Kingdom and United States, stamped) envelope.*

When the chips you need United States

Providing enzymes and reagents for genetic research and gene analysis.



At USB, we believe in leaving nothing to chance.

We know how important biochemicals are in your work. A we're dedicated to helping your research by supplying consisten superior enzymes and reagents at the lowest possible prices.

Our enzymes are carefully purified in our new research cent using state-of-the-art technology and equipment. Each of our pr ducts must pass a rigorous series of tests for purity and activi

You can count on us for innovative products of the highe quality at the best price — like GeneScribe™, the first a original T7 RNA Polymerase based transcription system.

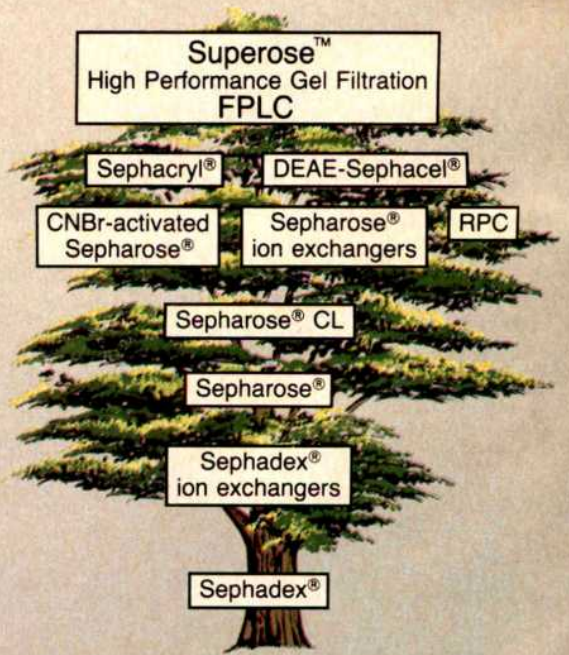
When you say "why FPLC" you are half way there...

... because Superose™ from Pharmacia is the peak of evolution in high performance gel filtration for the separation of labile biomolecules.

Over the past 25 years, Pharmacia has developed a broad range of chromatography media, including Sephadex®, Sepharose®, Sephacryl®, MonoBeads™, ProRPC™, and PepRPC™, together with the FPLC System, to meet the ever-growing requirements of experienced, innovative and demanding groups of researchers throughout the world.

Now, the FPLC System and Superose from Pharmacia allow you to use high performance gel filtration without the limitations imposed by silica and stainless steel.

With the introduction of Superose, the Pharmacia range of high performance chromtography media, including MonoBeads, ProRPC and PepRPC, has been extended to provide you with gel filtration media for fast, high resolution separations of biomolecules, from small peptides to large proteins and DNA-fragments.



- High performance prepacked glass columns
- Reproducible results
- High recovery of biological activity
- pH stability (1–14)
- Extended column life
- Pharmacia know-how

... so go all the way

Superose pre-packed glass columns with high chemical and pH stability, up to pH 14, provide you with unequalled flexibility in your choice of eluents and greatly simplify your column cleaning routines.

Superose allows you to perform rapid separations (20–60 min) while obtaining high resolution and high recovery, facilitating and improving your work in research, quality control or process development.

Superose has been especially developed for bioscientists and is optimized for high performance separation of proteins, DNA-fragments, peptides and other biomolecules.

Changing the objectives of research

The pressures on the British research enterprise, perhaps models of troubles that could arise elsewhere, are made worse by the government's lack of policy. But things may be changing.

WHAT follows is yet another account of the present agonies of the British system of publicly supported research, but that is not a signal to readers working elsewhere (by far the majority) to turn the page in search of something less parochial. For the British difficulty in adapting research and higher education to changing, and generally deteriorating, economic circumstances, is as vivid an illustration as there could be of the difficulties of changing course quickly in those fields. Even where the pace of economic growth is faster, so that the problems of containing spending within tight limits are less acute, there is plenty of evidence that the research enterprise is less flexible than it could be. Those who doubt that proposition should consider the condition of agricultural research in the United States, where attempts to reform the system going back for twenty years have mostly failed.

The British problem has it roots in the 1960s, the decade of relative prosperity when Mr Harold Macmillan, as prime minister, felt it proper to remind his electors that "you've never had it so good". That was the decade in which a threefold expansion of higher education was begun. It was also the decade when the British commitment to the European accelerator laboratory at Geneva was confirmed, and when the present pattern and scale of spending on civil science were determined more or less as they are at present. What else can have been expected of a decade in which the then Mr Harold Wilson (a later prime minister) offered before his election in 1964 a regenerated economy forged in the "white heat" of a technological revolution?

What has happened since is now a matter of record, much of it painful. Since the early 1970s, successive British governments of all kinds have been seeking to shed commitments on the grounds that they had become too expensive. The inquiry now under way under Sir John Kendrew to determine whether Britain should continue as a member of the European centre for high-energy physics (CERN) is not the first of its kind. Since the Rothschild reorganization in 1972, British government doctrine has been that the users of applied research should pay for it, with the result that many of the agents of research have become dependent for large parts of their budget not on the ministries that sponsor them but on a miscellaneous collection of other ministries with no administrative responsibility, either for efficiency or continuity. The present difficulties of the British Geological Survey, one of the largest identifiable components of the Natural Environmental Research Council, have arisen because its customers have become less willing spenders. Now the Agricultural and Food Research Council (AFRC) finds itself in the same case (see p. 8), facing the prospect that an as yet undetermined fraction of £10 million will melt away from its budget next year and probably twice as much in 1987-88. Similarly, British universities (and higher education generally) have for the past four years been made to survive on a budget unrelated to objectives of the enterprise, but instead determined as what the government considered it could afford.

Ignorance

Again in retrospect but also as a matter of immediate concern, the underlying difficulty is that British governments have set about the management of both higher education and civil science without sufficiently serious consideration of what these institution are intended to achieve. The present case of AFRC is a good illustration of how the government's attempt to manage this important part of the research enterprise is marked by what seems remarkably like ignorance of what research can do for an industry. It is not necessary to take sides in the dispute between the research council and the Cabinet Office about the yardsticks by which the scale of agricultural research should be determined to conclude that the system is being mismanaged.

The research council is the largest single agricultural research organization supported with public funds, and gets roughly half of its budget by way of research commissions from the Ministry of Agriculture, Fisheries and Food. But AFRC accounts for rather less than half of all the research supported by public funds in agriculture and related fields. Scotland, in this respect as in too many others, is separate. The ministry itself is responsible for fisheries research, forestry is parcelled out to the Forestry Commission while the ministry carries on its own books research laboratories intended to support veterinary services, among others. In short, there is a ragbag of arrangements for supporting agricultural research, which in normal times offers the advantages of plurality and diversity of research support, but when everything is being made to shrink makes it virtually certain that rationality will take second place after administrative convenience in decisions about which activities should be abandoned. That is one of the strongest reasons why the Scottish agricultural research stations should be united with those elsewhere in Britain, as a House of Commons committee recommended two years ago. The fact that the Scottish system is organized along the lines of the land-grant colleges of the United States (with researchers responsible for the provision of an extension service as well as innovations) should not be allowed to impede the more efficient distribution of effort and resources within this system.

Waste

The present system is also wasteful of such resources as there are. During the present financial year, AFRC will have spent more than £4 million on what is called "restructuring", the standard euphemism for the process of merging institutions and of persuading members of research staffs to take early retirement. Both in the research enterprise and in the British university system, this process has become a serious cause of wasted talents as well as money. As always, the people most willing to retire early are those who can most confidently expect to find something else to do, and who are likely by the same criteria to be most useful to the institutions from which they are displaced. While the theory of this process refers to something called the "managerial interest" by which applications for early retirement are judged, the academic world should by now be aware of the many talented British academic researchers who enjoy a premature pension and an academic salary from some other university system than the British. Is that a sensible way of hoping to turn a country's talent into national wealth? At the very least, the British government should be prepared to moderate the rate at which its research institutions are forced to contract by a sensible calculation of the speed with which that can be accomplished naturally.

Another irony running through recent experience of enforced contraction of the British system is that a government which is constantly complaining that academic research is indifferent to

the national economic interest is nevertheless apparently indifferent to the ways in which beneficial change might be accomplished. Thus the government's forecast of public spending published in January, which foreshadowed the further cuts which now threaten AFRC, boasts in passing that £2 million spent on the genetic improvement of pigs had yielded a benefit of £100 million a year to the pig industry, and that patented innovations in the design of agricultural mowers, themselves the products of a research programme costing £600,000, were yielding an annual income of £750,000 (to the British Treasury) by way of royalties. Sir Keith Joseph, who should know, was saying last week that the British government is soon to announce that such benefits will in future accrue to the organizations responsible — a promise first made in September 1983.

The issue is not merely one of equity, and of providing researchers with incentives to contribute to national wealth, but is also one of proper public administration. For how is it possible for people to make sensible decisions about the contraction of a research programme if they are required only to be concerned with costs? For AFRC, that issue is especially vivid in relation to plant breeding, for the council's excellent Plant Breeding Institute at Cambridge, which costs AFRC roughly £4 million a year, has recently been forced to cut back on staff ironically while the government is brooding on the question whether the National Seed Development Organization, which enjoys the right to market the institute's new varieties and which returned £2 million to the Treasury (half in tax) during its last financial year, should be turned into a private corporation. Why not lump the two institutions together, and let them make their own way in the world?

Core science

These lessons are not directly applicable to what remains the biggest upheaval under way in the British research enterprise, the attempt of the Science and Engineerng Research Council (SERC) to remould its programme of research support so as to release funds for the support of what is called "core science" (physics research for example) while remaining within the limit of a budget shrinking slowly in real terms. Three months of agonizing have identified the options between which the council will have to choose at its meeting later this month. As elsewhere, no decision is likely to avoid diseconomies of one kind (wasting talent) or another (wasting money).

This research council exists exclusively for the support of academic research but has been progressively since the early 1970s caught in the trap that what seemed the sensible provision of facilities for academic research have become institutionalized, representing growing commitments within a budget either stagnant or declining in real value. Astronomy has been one of the council's successes during this period. From a virtually standing start, the British community finds itself with access to new instruments built with SERC participation in Australia, on Hawaii, and now at La Palma in the mid-Atlantic. In Britain, there are three substantial institutions dedicated to the support of these distant telescopes, the Royal Greenwich Observatory, the Royal Observatory, Edinburgh and the Rutherford Appleton Laboratory (which has its finger in many other pies as well). Not all of these can survive the month ahead. The betting seems to be that Britain will pull out of its Australian connection, leaving behind not merely the Anglo-Australian telescope but the excellent Schmidt telescope on the same site, operated for the time being by Britain alone. The obvious difficulty is that funds must somehow be saved, but that it would be too galling, and also uneconomic, to think of pulling away from La Palma, where construction is still under way. But even in the present complicated state of the politics of international observatories and of quotas of observing time, is it entirely beyond the bounds of possibility that a broader international base for construction of the La Palma observatory would keep more facilities alive and accessible? Back in the United Kingdom, it is also clear that one, the other or perhaps both of the observatories must go, but again it is important that neither talent nor money should be wasted for the sake of administrative tidiness. Should not SERC be looking for some way in which the good work these laboratories do (in the development of instruments and the retrieval of data) could be transferred intact to universities, which are not often enough (in Britain) trusted with the execution of projects?

Another of SERC's problems is the clutch of machines that have been built as central facilities for university groups, but which are unlikely to be fully used in the years ahead for lack of funds for the general support of university researchers. There are lasers and synchrotron radiation sources, a neutron spallation source and nuclear structure facility. Again in retrospect, these machines were plainly commissioned too light-heartedly, without a sufficient calculation of whether SERC could afford to support enough customers to keep them fully used. The simple solution is that one or even two of these machines should be abandoned. The more complicated but better solution is that SERC should be enabled to shake free the shackles of chauvinism required of those who spend public money, and make whatever deals may be possible elsewhere in Europe for the continued use of facilities whose virtues, while not necessarily unique, are far from negligible.

SERC's biggest problem in the months ahead is, however, the decision that must be made about the subscription to CERN. The Kendrew committee has not yet reported, and may not until April, but there are only two things it can say — Britain cannot afford to continue to belong to CERN while the cost robs basic science of funds, but equally cannot afford not to belong. So there will be a period of further introspection, the issue will fall to be resolved by the government, which may or may not provide the extra cash that would be needed to square Kendrew's circle. But that will be a shabby way in which to deal with a serious problem — and what is in effect a treaty obligation. Walking out of CERN would not merely confirm mainland suspicions that Britain is a reluctant European but would damage an important laboratory at a particularly interesting time in its development. What the government (and SERC in its own interests) might reasonably expect, however, is that the future development at CERN, beyond the machine now planned (called LEP, an electron-positron collider), should be undertaken on a different financial basis, perhaps involving only the enthusiasts and the very rich. That way, the scale of SERC's dilemma would be limited in time.

What chance is there that the British government, hard-faced as it has been in the past five years, will listen to this special pleading? On past form, not much. But there is now at least a chance that the tide may be on the turn. After setting its face against the natural growth of student numbers at British universities, the government is now about to announce a planned increase, sufficient to yield about 1,000 graduates a year in science and engineering. Similarly, it seems the government has been more flexible that expected over the extra cost of continued membership of the European Space Agency. In each case the budgets of other ministries have been raided so as to provide urgently needed funds for education and science, necessary for carrying through policies on which the government has decided. Is it possible that a government whose reputation is for inflexibility has begun to appreciate that policies and not book-keeping should dictate the pattern of its spending?

That must be the hope. The British government's case for containing public spending within strict limits is strong. The need will continue for years to come. There may also be something in the government's constant complaint that the British investment in research has not yet been as productive of profitable innovation as might have been expected. But during the past five years, the management of the system has taken the form of publishing once every year figures showing what costs will be allowed and then grumbling from the sidelines. As anybody could have predicted, and as many did, the result within the system has been diseconomy. Nobody will suggest that governments, or even civil servants, should take on themselves the direction of research. But if they spend upwards of £500 million a year on these activities, they cannot walk away from the need, first, to help define their expectations and, second, to ensure that the resources are available. □

British higher education

Modest increase planned in student numbers

THE British government plans to announce next week an increase in the numbers of students following science and engineering courses at universities. This decision is the outcome of government alarm during the past two years at the shortages of trained people free for recruitment to British industry. But to many academics, the development will seem like the light at the end of a four-year tunnel.

The intention is that between £40 and £50 million should be spent over the three years beginning in September on the provision of extra places in science and engineering. Some of the money will come from the budget of the University Grants Committee, but the novelty of the plan (due to be made final at a meeting on Wednesday, 6 March) is that other government departments will be contributing. The Department of Trade and Industry and the Department of Energy are among those that have agreed to contribute from resources they would otherwise have spent on their own account.

In one respect, the new development is an outcome of the plan, widely canvassed a year ago, for organizing a "switch" within British higher education from the arts and humanities to science and engineering. That was frustrated by the unwillingness of departments other than the Department of Education and Science to pay up. One feature of what is now intended is that the increase of science places (smaller than first planned) will not be offset by an actual reduction of the places available in the arts and humanities.

The scheme about to be launched will apply only to the universities. Although, in early discussions, the possibility was canvassed that polytechnics might also be included, representations by employers to the Department of Trade and Industry seem to have convinced the government that university graduates are most needed.

One of the questions to be decided on 6 March is whether the Open University and Cranfield Institute of Technology, which are supported directly by the Department of Education and Science, should participate.

The intention is that formal applications for a share of the newly available resources should be invited from universities during April, and that funds should be available both for supporting courses and for modest building projects. The urgency of the timetable the government has set for itself is dictated by the need to get things started at the beginning of the next academic year.

Among those participating in the planning of this new departure are some who fear that students with school-leaving qualifications of the kind required by most university engineering courses may not be available in sufficient numbers in the years immediately ahead.

Among academics, the chief import of the new development will seem to be the evidence it provides of a new flexibility in the British government's management of resources. Some think that the partial defeat last year of Sir Keith Joseph's attempt at redistribution within his own budget may have persuaded ministers that the system had become inflexible. □

Space budget fixed

A FEW weeks ago, the UK Science and Engineering Research Council (SERC) was beside itself with worry over how to pay an increased mandatory subscription to the European Space Agency (ESA), to pay for ESA basic science. But now, in an important decision of principle by the British government, it appears that SERC is to be taken off the hook.

The trouble began in January when European space ministers agreed a 10-year programme for ESA. The programme included a three-per-cent annual increase (eight per cent in UK cash terms) for the next five years in the ESA science budget. The straitened SERC, which belongs to the budget of the Department of Education and Science (DES), could not pay. Yet the subscription was due if the Department of Trade and Industry (DTI) was to participate, as it wished to do, in ESA's plan to join the US space station. The usual Treasury procedures did not allow DES to claim the increase from DTI.

Deadlock seemed likely. But now, according to DES, "SERC's additional costs are likely to be shared among various departments" — a statement that marks a fundamental breaking of interdepartmental barriers.

Meanwhile, discussions over a possible British "space centre" appear to be faltering over the location and powers of the centre. Several sites are being considered. Another less auspicious possibility is that the "centre" would be no more than a mere coordinating committee. Robert Walgate

US supercomputers

Four research centres named

Washington

THE National Science Foundation (NSF) has finally put its money where its governing board's mouth has been and awarded a total of $200 million to set up supercomputer centres. They will be at the University of California at San Diego; Cornell University, in Ithaca, New York; the University of Illinois, Champaign-Urbana; and Princeton, New Jersey, near the campus of Princeton University.

Location	Machine	Director
San Diego	Cray XMP	Sidney Karin
Champaign-Urbana	Cray XMP	Larry Smarr
Ithaca	IBM 3084 QX/ FPS 164s and 264s	Kenneth Wilson
Princeton	CDC Cyber 205 (after 1986, ETA-10)	Steven Orszag

NSF is to provide each centre with between $7 million and $13 million a year for the next five years for the purchase and operation of the equipment. Users will not have to pay for computer time, which will be allocated both by NSF directly — in the case of requests for large blocks of time submitted as part of NSF grant applications — and by research committees at each centre. NSF officials expect a roughly 50-50 split between these two.

Two years ago, a working group of the National Science Board, NSF's governing body, called for a $200 million investment in ten supercomputer centres on the grounds that "important science" was already being neglected in the United States for lack of supercomputer capacity. The recommendation was received more warmly by Congress than by the administration's budget-writers. So far, NSF's official response has been to buy time on existing supercomputers, underwriting the equipment, such as terminals and communications networks, that academic researchers have needed in order to gain access to those machines.

Under the contracts announced last week, the states in which the four centres are to be located will contribute an average of about $20 million each. The host institutions will contribute about $10 million each, mainly in land and buildings, while computer manufacturers will supply an additional $50-$70 million, mainly by giving equipment or providing it at reduced prices.

According to NSF, the four host institutions, together with 28 other universities that will be affiliated with the San Diego and Princeton centres through two consortia, will be able to "influence policies and procedures" of the centres but will have to compete on an equal footing with all users for time. The centres are expected to begin operating in late 1985 or early 1986. **Stephen Budiansky**

US-Australian defence

Hawke fights on second front

Canberra

THE Australian Labor government seems to have successfully contained the damage that might have been done by last month's visit to Washington by Mr R. J. (Bob) Hawke, the Prime Minister. The issue is Mr Hawke's widely reported reversal of an earlier decision to provide logistical support for two US MX missile tests to be held this year in the Tasman Sea, off Australia's east coast. The government had feared that internal faction fights would cause trouble. Stiffer tests of consensus are to come, however. Mr Hawke has come under continuing pressure from the United States to strengthen US-Australian bilateral defence agreements and to promote the growing isolation of neighbouring New Zealand, following that country's refusal of port facilities to a nuclear-capable US warship earlier this year. The three countries are bound together militarily by the ANZUS treaty. On 4 March, however, Mr Hawke announced that the next ANZUS council meeting scheduled for July had been indefinitely postponed. Strictly speaking, under the treaty the three countries are obliged only to "consult together" in time of threat. But in practice ANZUS has been the formal basis for the US security guarantee to Australia and New Zealand for thirty-three years. Cancellation of the council meeting signals its likely imminent demise.

Mr Hawke's difficulties began immediately before his departure from Australia on 2 February for meetings in the United States with President Reagan and Secretary of State George Schultz, when he was reported to have agreed, without consulting his full cabinet or caucus, to provide facilities for US monitoring of the MX splashdown area.

The agreement would have fulfilled an undertaking by former prime minister Mr Malcolm Fraser, and would have made it possible to test the accuracy of the four-stage missile over its full range of 14,000 km, rather than over the shorter Vandenberg-Kwajalein range. With ten 350-kiloton warheads, the accuracy of the MX over a distance of 7,000 km is approximately 90 metres using NAVSTAR guidance.

Under pressure from the Labor Party's left wing, Mr Hawke cabled from Brussels on 6 February (the day before he was due to meet President Reagan) his decision to withdraw from the tests. The switch was made to look even more humiliating by Mr Hawke's exhortation three weeks earlier to New Zealand Prime Minister David Lange to rescind his decision to deny the use of port facilities to the destroyer USS *Buchanan* if the ship were to be carrying nuclear weapons, an item of information routinely refused by the US Navy.

Despite the MX fiasco, Mr Hawke has been let off much more lightly by Washington than has Mr Lange. There appear to be several reasons for this. One is a desire to counter the growing influence of the Australian government's left wing, another to send a message to wavering NATO allies emboldened by Mr Lange's

actions, and a third the importance the United States attaches to its Communications Command Control and Intelligence (C^3I) bases on Australian soil.

Information about these installations is scarce and more likely to be uncovered in US publications or under the US Freedom of Information Act than through Australian government channels, but there are thought to be more than two dozen of them.

The continued presence of these stations in Australia has become a contentious issue. Critics of the facilities at Pine Gap and Nurrungar (see below) in particular charge that whatever their value when they were commissioned, during the "deterrence" years, they are now (or could become) part of a first-strike "counter-force" system and hence nuclear targets. This strikes at the heart of Mr Hawke's embattled strategy for peace and disarmament, a major plank of government policy.

The New Zealand government is soon to become even more isolated militarily after Mr Hawke's announcement last week that New Zealand will in future be denied the usually generous US component of the intelligence "product" formerly shared among the United States, United Kingdom, Australia and New Zealand and Canada under the 1947 UKUSA secret treaty. Practical problems of intelligence separation have arisen for the Australian government because intelligence from the "joint facilities" combines information from shared sources as well as that gathered solely by Australia. This is compounded by the presence (on secondment) of New Zealand intelligence officers in several sensitive Australian installations. Mr Hawke must now deal with the looming policy problems of south-west Pacific regional defence, at the same time avoiding the impression that Australia is dumping a small idealistic neighbour at the behest of the United States. **Jeffrey Sellar**

US defence facilities in Australia

OFFICIALLY referred to as "joint US-Australian facilities, the most important US defence installations in Australia are, according to Dr Desmond Ball of the Australian National University, the following.

Naval Communications Station *Harold E. Holt*, North West Cape.

Operational since 1967, this station maintains reliable communications with the nuclear-powered ballistic missile submarines of the US fleet patrolling the Pacific Ocean. The VLF (Very Low Frequency) facility is the largest and most powerful in the US worldwide communications system. North West Cape also has an array of high-frequency transmitters used for US military operations in the Indian and Western Pacific Oceans, as well as a ground station for the US Defense Satellite Communications Systems (DSCS).

Joint Defense Space Research Facility, Alice Springs (known as Pine Gap).

Operational since 1969, the facility is 19 km south-west of Alice Springs and consists of seven large radomes and a large computer complex. Pine Gap was originally established as part of Project Rhyolite, which involves a small number of very large antenna-carrying signals-intelligence (SIGINT) satellites in geostationary orbit. The facility monitors a wide spectrum of Soviet and Chinese military communications and radar transmissions, allowing the mapping of the extensive Soviet early-warning and air defence networks, as well as telemetry data transmitted during Soviet ballistic missile tests. This is the principal means of monitoring Soviet missile developments, and hence Soviet compliance with the strategic arms agreements.

Joint Defense Space Communications Station, Woomera (known as Nurrungar):

This is within the Woomera restricted area, 480 km north-west of Adelaide, and with Buckley, Colorado, is one of the two ground stations for the US satellite early-warning system. Nurrungar provides a real-time link between the North American Air Defense Command (NORAD), Strategic Air Command (SAC), the national military command system and the satellite early-warning system. Data are derived from infrared, charged particle and radiation sensors aboard the geostationary satellites of Program 647 of the Defense Support Program (DSP), which detect missiles shortly after lift-off. **Jeffrey Sellar**

Polish universities

Government legislation unwanted

Warsaw

THE "public debate" over Poland's 1982 Higher Education Act is becoming, more and more, an open confrontation between the universities and the government. A referendum last week among academic staff at Warsaw Universitiy gave an overwhelming vote of "no" to the proposed changes. (More that 75 per cent were against the reduction of the size of the senate, and more than 80 per cent against all other reforms.) A similar referendum among the students, now in progress, seems likely to give even more conclusive results. Yet the votes are unlikely to make any real difference. The government, it is believed, will simply push through the changes.

According to those who oppose the reforms, the changes would effectively annul the academic autonomy gained in the Solidarity period. Rectors and deans, at present elected, would be nominated by the Minister of Science and Higher Education, who would also have wide powers to suspend or dismiss staff, students and academic bodies. Political as well as professorial considerations would be taken into account in hiring university staff, and the "students' self-government committees" would be replaced by new bodies, based on the party-linked youth organizations.

The government case is that, since the state supports the universities, the state has a right to decide what goes on in them, and, in particular, to ensure that they are not used for anti-socialist purposes. The proposed changes in the act would therefore stress the explicitly "socialist" nature of Polish education, and wide disciplinary powers in the case of alleged "anti-socialist action" by staff or students. (The definition of such action will, it appears, be wide according to sources in Warsaw Polytechnic. The rector of that institution is under pressure from the ministry to discipline students who carried the polytechnic's banner in the funeral procession of the murdered pro-Solidarity priest Father Jerzy Popieluszko, last autumn.) All that is happening, one ministry spokesman tried to explain, is that the Committee for Social and Political Affairs if trying to plug a few loopholes in the 1982 act, which have been used by opponents to destabilize the universities.

The academics, on the other hand, maintain that nothing is more likely to destabilize the universities than constantly changing the law.

The Main Council of Higher Education (which consists of one delegate from every university and higher college in Poland, with the exception of the Catholic University of Lublin) has repeatedly made the point that the present act should be allowed to run for the term of office of the rectors elected in 1984 (until 1987), before any changes are discussed.

One scholar formerly active in the unofficial Society of Academic Courses, the "Flying University" of the late 1970s, went so far as to say that what is at stake is not the election versus appointment of rectors, nor the existence of the "student self-government committees", nor even the right of the minister to suspend or dismiss recalcitrant staff or students. "What we are fighting for", he said, "is to ensure that the government cannot simply change the law every time it wants to interfere in the universities". **Vera Rich**

UK research

Joseph warns of trouble ahead

THE whole of the British research establishment spent two hours at the Savoy Hotel last week to hear Sir Keith Joseph, the Secretary of State for Education and Science, deliver a speech whose preparation cannot have taken nearly as much time as that needed to feed the multitude. He was speaking at the annual luncheon of the Parliamentary and Scientific Committee.

Sir Keith had three points to make, of which the clearest was that the scientific community should address itself to the "moral dilemmas" occasioned by new developments in research. He said that the parliamentary bill introduced by Mr Enoch Powell MP, which would ban the use of human embryos for any purpose other than the treatment of infertility, is only "an introduction" to the troubles that lie ahead.

On support for research by the government, Sir Keith said that his partially successful attempt to transfer funds from student maintenance grants to research support had broken new ground by uniting all sections of his party in opposition. He went on to chide scientists in his audience because, he said, among the "uncounted" letters of protest about student grants, there had so far been found none — "not one" — applauding his attempt to increase research support.

Borrowing from C.P. Snow, Sir Keith also wrung his hands last week over what he called "the two cultures" of "science and trade". He complained of the "suicidal snobbery of academic attitudes" towards trade, arguing that the stagnation of British support for research is a consequence of poor economic growth in recent years.

But Sir Keith said there are now "harbingers of improvement" to be found both in the rate at which new enterprises are being created in Britain and in developments such as that of the complex of science-based industries recently grown up around Cambridge. **John Maddox**

British AIDS

New cases cause alarm

SINCE the summer of 1982, 132 cases of acquired immune deficiency syndrome (AIDS) have been diagnosed in Britain, 58 of which have proved fatal. But not until last month was public anxiety about the disease fanned, following the publicity given to the death of a prison chaplain.

The Department of Health has now set up an expert advisory group representing science and medicine and public health services. The disease has not been made notifiable, although patients with AIDS are reported to the Communicable Disease Surveillance Centre by their doctors. Government policy is fivefold:

- Guidelines for all health professionals.
- Health Education Council leaflets to promote public awareness of the disease particularly among "at risk" groups (male homosexuals and intravenous drug abusers).
- Safeguarding of recipients of blood and blood products. Blood transfusion centres are distributing widely a leaflet *AIDS: Important New Advice for Blood Donors*; the British AIDS charity (the Terence Higgins Trust) and the Blood Transfusion Service are asking "at risk" people not to give blood.
- Development of tests to screen blood donations for the AIDS virus antibody.
- Speeding-up of the programme to produce heat-treated factor VIII (the blood-clotting factor) used to treat haemophiliacs. The Haemophilia Society is selling a comprehensive booklet about AIDS.

The government's financial commitment to AIDS research consists of £158,000 from the Medical Research Council (MRC) over three years (from October 1984), supplemented by £15,000 a year from the health department. MRC has also committed £27,000 for two years (with £7,000 a year extra from the health department) for research on the relationship of AIDS to patients with blood disorders. The US AIDS research budget is $86 million a year (see *Nature* 28 February, p.725).

The AIDS virus has been isolated independently in three different laboratories and has been variously named the lymphadenopathy-associated virus (LAV), human T-cell leukaemia/lymphoma virus (HTLV) type III or AIDS-associated retrovirus (ARV). It is now recognized that all three are variants of the same virus (see *Nature* **313**, 636 and 743; 1985) whose nucleotide sequences differ by 1 per cent and whose genetic organization is identical. The AIDS virus is thought not to be a member of the HTLV family of retroviruses, but to represent a new class.

According to Department of Health figures, 90 per cent of deaths due to AIDS in Britain have been male homosexuals of average age 36. **Maxine Clarke**

Genetic manipulation

Rifkin battle lost, war undecided

Washington

A PANEL of the US Court of Appeals has ruled invalid a lower-court injunction forbidding the National Institutes of Health (NIH) to approve any deliberate-release experiments (see *Nature* **312**, 689; 1984). But the Lindow experiment on frost-resisting bacteria is still held up pending approval of a formal document assessing its environmental risks.

The lower-court injunction, granted to anti-genetic-engineering activist Jeremy Rifkin, had ordered NIH's Recombinant DNA Advisory Committee (RAC) to prepare a lengthy "environmental impact statement" before considering any other proposals for field trials of recombinant organisms. NIH officials said that preparing such a document would have taken a year and would itself have been subject to further legal challenges.

The Lindow experiment, in which genetically-modified bacteria would be sprayed on potato plants to protect against frost damage, was to be the first in which bacteria containing recombinant DNA were to be released to the open environment. The experiment was approved by RAC in June 1983; in August of that year, Rifkin sued in federal court to halt it.

Although the appeals court has removed the biggest threat that Rifkin held over RAC — the prospect of tying up all deliberate release experiments in years of legal manoeuvring — it left no doubt that NIH did not follow the law in approving the Lindow experiment without first completing a formal environmental assessment. The court said that environmental assessments would likewise be required for each deliberate-release experiment that comes before RAC.

As for the Lindow experiment, it is now apparently up to the lower court in the person of District Court Judge John Sirica to decide whether the environmental assessment that the RAC staff has in fact just completed on the experiment is adequate. Rifkin's lawyer has raised the possibility of challenging that point. Rifkin himself has said on several occasions that he does not believe that there is at present sufficient knowledge fully to assess the environmental risks posed by the deliberate release of recombinant organisms.

The court's ruling also opens the way for routine legal challenges of every deliberate-release experiment that comes before RAC on the grounds that the environmental assessment is inadequate.

NIH are meanwhile taking steps to get out of the business altogether. The Environmental Protection Agency (EPA) intends to regulate all field trials of "microbial pesticides" that have been genetically altered or manipulated; under new EPA rules, the agency would have to be given 90 days' notice of any such test. (Previously, EPA regulations applied to field trials of pesticides only when the test plot exceeded 10 acres.)

EPA is also working on regulations that would apply to field trials of other recombinant organisms as well. At the next RAC meeting, scheduled for 3 May, the committee is expected to approve a proposal that would allow researchers subject to the RAC guidelines (currently any institution that receives federal funds for recombinant DNA activities) to go ahead with deliberate release experiments so long as they have approval from another federal agency; RAC approval would no longer always be required.

RAC has not received any new proposals for deliberate-release experiments from federally-funded institutions since the Lindow approval went to the courts. Two private companies, however, Advanced Genetic Sciences (which proposed an experiment virtually identical to Lindow's) and Cetus Madison (which proposed a plant experiment), voluntarily submitted proposals last year; RAC approved them, but the NIH director, James Wyngaarden, decided that even though the injunction did not apply to private companies (which are not legally bound by the RAC guidelines), there should be no double standards, so he is holding up approval until environmental assessments are prepared for them. Advanced Genetic Sciences has since withdrawn its proposals and has decided to deal only with EPA; Cetus Madison has been told that if it still wants its proposal considered by NIH, it should submit a draft environmental assessment.

Stephen Budiansky

Court wishes plague on both sides

THE following are extracts from the opinion of the United States Court of Appeals in the case in which NIH appealed from a ruling of the lower court awarding an injunction on deliberate-release experiments to the Foundation on Economic Trends, Mr Jeremy Rifkin's organization.

Judge Wright

This appeal presents an important question at the dawn of the genetic engineering age: what is the appropriate level of environmental review required of the National Institutes of Health (NIH) before it approves the deliberate release of genetically engineered, recombinant-DNA-containing organisms into the open environment?

We emphatically agree with the district court's conclusion that NIH has not yet displayed the rigorous attention to environmental concerns demanded by law. We therefore affirm the district court's injunction prohibiting the University of California deliberate-release experiment until an appropriate environmental assessment is completed. We also share the district court's view that NIH should give greater consideration to the broad environmental issues attendant on all deliberate release of organisms containing recombinant DNA, and to its own responsibility for approving these deliberate-release experiments. We find, however, that the part of the injunction enjoining NIH from approving all other deliberate-release experiments is, at this juncture, overly broad, and we therefore vacate the part of the injunction that prohibits NIH approval of those experiments. We emphasize, however, that if NIH fails to give appropriate environmental consideration to any other experiment, as it has failed to do with the University of California experiment, injunctive relief would be clearly proper.

Broad claims are made about both the potential benefits and the potential hazards of genetically engineered organisms. Use of recombinant DNA may lead to welcome advances in such areas as food production and disease control. At the same time, however, the environmental consequences of dispersion of genetically engineered organisms are far from clear.

The Lindow experiment

On September 17, 1982, Drs Lindow and Panopoulos, scientists at Berkeley, submitted a request for NIH approval of an experiment that would involve deliberate release of genetically altered organisms in the open environment. NIH approval was required because the University of California receives NIH funds for recombinant DNA research.

Neither the government nor the university seriously disputes that an environmental assessment is necessary. The university's contention here is that the environmental consideration given by NIH was equivalent to the necessary environmental assessment that the injunction requires only a document labelled "Environmental Assessment".

We thus fear that the university and the government completely misapprehend the district court's holding and the requirements imposed by NEPA [the National Environmental Policy Act]. The most glaring deficiency in NIH'sreview of the Lindow-Panopoulos experiment is its treatment of the possibility of dispersion of recombinant-DNA-containing organisms. An environmental assessment that fails to address a significant environmental concern can hardly be deemed adequate for a reasoned determination that an EIS [environmental impact statement] is not appropriate.

NIH procedures

The district court also found that plaintiffs were likely to succeed in showing that NIH should have completed an EIS (1) in 1978, when it revised the guidelines to make deli-

berate release possible, and (2) in 1982 or 1983, when it became clear that NIH would be receiving proposals for deliberate release. The district court thus enjoined NIH from approving all other deliberate release experiments. The emphasis on the 1978 revision is misguided for two reasons. First, the policy revision did not irrevocably commit NIH to any decision. Second, significant changes have occurred since 1978, including the maturation of genetic engineering to a point where deliberate release is feasible and imminent. It makes little sense to rest a judgment on *prospective* relief on decisions made several years ago in different circumstances.

The Supreme Court has emphasized that the question of preparing a programmatic EIS [which plaintiffs argued NIH should have prepared in 1982 or 1983] is initially committed to the agency. We are not prepared to agree that plaintiffs are likely to succeed in showing that the absence of a programmatic EIS unreasonably constricts adequate environmental evaluation.

Judge MacKinnon, concurring

I am of the opinion that the foundation should have made its original application to NIH. This is not a case of just failure to exhaust [administrative remedies], but a case of a complete failure of the foundation to present any claim whatsoever to the agency — NIH.

I can understand how the RAC scientists who are knowledgeable in this field of genetic engineering would approve the experiment by a vote of 19-0 with no abstentions. It would seem that an experiment that releases into the environment organisms substantially the same as some already living there, and subject to the same naturally occurring controls, would present no risk. However, the general public and those who have to pass on this action are not knowledgeable in this field and they are easily frightened by new scientific experiments and their possible consequences. It is such lay concerns that must here be satisfied by Environmental Assessments and Impact Statements.

Due notice of the pendency of this matter was given in the *Federal Register* and comment was invited, but none was forthcoming. Had the objections of the foundation been alertly raised before the agency, the district court and this court would undoubtedly have had a better record to consider and might even have been spared the necessity of ruling on the case.

The foundation's conduct has also delayed this vital experiment for a very considerable period of time. The use of delaying tactics by those who fear and oppose scientific progress is nothing new. It would, however, be a national catastrophe if the development of this promising new science of genetic engineering were crippled by the unconscionable delays that have been brought by litigants using the National Environmental Policy Act and other environmental legislation in other areas. □

Star wars

Quarrel over congressional study

Washington

THE Congress's Office of Technology Assessment (OTA) has reacted angrily to accusations that its study of President Reagan's "star wars" Strategic Defense Initiative (SDI) is "designed to kill SDI rather than examine it". The accusations were made last week by Lieutenant General Daniel Graham, a former member of the advisory panel overseeing OTA's study and a prominent champion of space-based missile defences. OTA says there is "no basis whatever" for Graham's attacks and accuses him of breaking faith with OTA's study by distributing confidential documents to senators and to a senior official in an (unnamed) executive agency.

Graham is director of the High Frontier organization, which is widely thought to have been influential in persuading President Reagan to instigate research into missile defences. Graham resigned from the OTA panel on 2 February after being told by OTA's director John Gibbons that he must undertake to keep OTA study documents confidential in order to remain on the panel. Graham admits distributing confidential OTA documents annotated by himself to three senators and the executive official. Graham's explanation for his action is that "this concerns national security and I consider that more important than their damn procedures".

Graham's charges extend both to OTA staff, whose study drafts he describes as "utterly biased", and the advisory panel, which he says is "heavily stacked with highly vocal opponents of SDI". OTA replies that Graham chose to list only those members with whom he personally disagrees; the panel has 21 members in all, chosen to represent all major points of view. Sidney Drell of Stanford University, a critic of SDI who appears on Graham's list, dismisses Graham's charges as "patently false". Another accused panel member, Richard Garwin, praised the work of the OTA staff and the panel chairman. The panel's chairman, Guyford Stever of Universities Research Associates, did not wish to comment on Graham's charges in the interests of maintaining neutrality.

One section of OTA's draft report which particularly incensed Graham lists possible goals of SDI and evaluates them. According to Graham, OTA "stated that a goal is to provide means for the United States to credibly threaten the use of offensive nuclear weapons should it so choose". OTA replies that Graham's quote is taken out of context; the draft did not suggest that this was the actual objective of SDI. Another of Graham's objections is that the report "attempts to make the issue a choice between the Anti-Ballistic Missile (ABM) treaty and SDI".

The issue that brought to a head the row between Graham and OTA was an attempt in the report to separate the issues of anti-satellite weaponry and ballistic missile defence. Graham says this was done to weaken the case for SDI; after unsuccessfully challenging OTA's authority to do so, he took his arguments to senators, and at least one senator has made representations to OTA about the study, says Graham.

OTA is no stranger to star wars controversy; last year, a background paper prepared for the study by Ashton Carter of Harvard University was vilified by Lieutenant General James Abrahamson, director of SDI. Carter's report concluded that the prospect of a near-perfect defence against nuclear missiles was so remote that it should not form the basis of public policy. Graham says he hopes his resignation will serve to discredit the latest OTA report; on the other hand, as one panel member pointed out, it also means there is now one fewer SDI supporter on the panel. **Tim Beardsley**

British cooperation

Washington

FOLLOWING the recent endorsement of SDI research by British Prime Minister Margaret Thatcher during her visit to Washington, negotiations are now under way here to determine how Britain might best cash in on the effort. The SDI office has made it plain that it welcomes allied research cooperation ("we need all the help we can get") and says "the ball's in their court". One major obstacle, however, is that Article IX of the ABM treaty, signed by the United States and the Soviet Union in 1972, expressly forbids the transfer to third parties of anti-ballistic missile technology covered by the treaty. A statement agreed between the signatories makes it clear that the article covers the transfer of "technical descriptions or blueprints specially worked out for the construction of ABM systems or their components". But Britain, and presumably other allied nations, would seek agreements guaranteeing just such tranfers.

The British negotiations in Washington are being led by Dr John Green, deputy head of the embassy's defence staff. One option is that a memorandum of understanding might be exchanged between the two governments; an objective of the negotiations is to establish a coherent framework for British research institutions and companies wanting to offer their expertise to the SDI office. As cost does not seem to be a major object in SDI, there should be plenty of opportunity for qualified British scientists to jump on the bandwagon. But first there will have to be a detailed scrutiny of research capabilities in relation to needs; the results are likely to remain classified. Tim Beardsley

Agricultural research

British council under new threat

THE least favoured of the British research councils, the Agricultural and Food Research Council (AFRC), is faced with yet another period of contraction. At the end of a year in which it has shed 550 jobs, one-sixth of the total, the council is now faced with the prospect of a further reduction of research commissioned by the three agriculture ministries, the Ministry of Agriculture, Fisheries and Food and the ministries for Scotland and Northern Ireland.

This is the gloomy theme of the second of the council's corporate plans, published earlier this week. Sir Ralph Riley, the secretary of the council who retires on 1 April, says in his preface to this document, which will become the basis of the council's claim on public funds in the financial year beginning in April 1986, that a revised plan may be necessary when the government's intentions are known.

The discontent of successive British governments with the council's work goes back at least to an internal inquiry in the late 1960s. At the time of the Rothschild reorganization in 1972-73, AFRC was the most directly affected, being required to depend on commissioned research from the agriculture departments for 75 per cent of its budget. In the past decade, the volume of commissioned work has steadily declined, as has the council's share of the science budget (from which all research councils are supported). Two years ago, the council formally dissented from the annual allocation recommended by the Advisory Board for the Research Councils (ABRC).

In the financial year now ending, AFRC and the Scottish institutes will have received £46.7 million from the science budget and the remainder of the total of £121.6 million by way of commissions. The planned increase of the cash budget for 1984-85 to £125.6 million (not fully compensating for inflation) includes an increase of £3.6 million from the science budget and of £0.5 million in commissioned research.

Government forecasts of public spending published last December show the total budget standing at £126.8 million three years from now (in 1987-88), but the corporate plan says that even this static budget has now been put in doubt by the planned reductions of departmental research and development of £10 million in 1986-87 and of £20 million in 1987-88.

The council is particularly sore at the way in which a Cabinet Office paper published at the end of last year used a comparison of agricultural research costs and output values in the countries of the Organisation for Economic Cooperation and Development (OECD) to demonstrate that Britain spends a greater proportion of the value of agricultural output on research and development than other countries. The assertion was quickly denied (*Nature* 3 January, p.8), and the corporate plan published this week says that other indicators would lead to different comparisons. Yet senior officials of the council fear that the Cabinet Office comparison is still being "hawked around Whitehall" to try to discredit its programme of research.

For the rest, AFRC seems not to have won the moral support it might have expected from the newly-formed Priorities Board on Research and Development in Agriculture and Food, which has apparently been asked to consider what steps could be taken to increase industrial sponsorship for the council's research. The board has apparently taken the line that the central government should pay only for what others cannot be expected to pay for.

The corporate plan says that if the council's budget is further reduced, "further restructuring" may be necessary. During the past few years, this has chiefly meant the closing of research stations and the shedding of staff, but now there is also talk of allowing some parts of the agricultural research enterprise to become free-standing. The possibility that there may be a merger of AFRC and the Scottish research stations is also being explored. □

Planned contraction

THE chief ingredients of the new corporate plan for agricultural research, covering both the work of AFRC and the Scottish stations supported directly by the Department of Agriculture and Fisheries for Scotland are as follows:

University research. The plan is that spending on research grants (increased by 8.5 per cent to £5.4 million this financial year) should continue to take a larger share of total funds. By 1989-90, the plan says, £7 million a year will be spent in this way, with priority given to food research.

Food science. The plan says that AFRC has warmly endorsed the recommendations of the Advisory Council for Applied Research and Development (ACARD) in 1983 that more attention should be paid to food science. Research spending will increase from £13.3 million this year to £19.3 million five years from now, or by 26 per cent in real terms. The plan is to concentrate this work on the three research stations at Bristol, Norwich and Reading, but other council research institutes will also be involved.

Animals research. The intention is that spending on animal diseases should decrease by 16 per cent (to a cash value of £16.4 million a year) over the next five years. Part of the council's recent restructuring has entailed the merging of the Grasslands Research Institute and the National Institute for Research in Dairying at a new site at Hurley, in Berkshire. During the coming year, the Animals Research Institute at Cambridge will be merged with its parent station at nearby Babraham.

Forage crops. The corporate plan outlines a strategy on concentration of research under the umbrella of the Animals and Grasslands Research Institute, with the Welsh Plant Breeding Research Institute and its two Scottish equivalents taking more tightly defined roles within the whole. Plant protection research will decline in the next five years by 16 per cent.

Capital development. The plan says that the recent tendency to spend 12 per cent of the AFRC budget on buildings "cannot be sustained", and that it will in future not be possible to replace some obsolete equipment or even to provide the material support for some new research programmes. But the council plans to earmark £3.5 million from the budget for the year after next to support initiatives not yet proposed.

Manpower. In the year now ending, 100 of the 550 posts lost from the AFRC establishment have been compulsorily vacated. The earlier contraction of AFRC, not yet completed, entails the loss of a further 250 posts during the coming year; the new plan says that it will also be necessary to lose a further 800 posts in the next two years, offset by an increase of 60 posts for food research. The rule that people should retire at age 60 will be strictly enforced, and as many as possible of those not needed will be persuaded to take early retirement. □

Schopper to stay

THE European Organization for Nuclear Research (CERN), near Geneva is to be directed for a further four years by the present incumbent, Professor Herwig Schopper of West Germany. He will thus remain director-general until the end of 1988, which should see the end of the large electron-positron collider (LEP) project.

Italy, which had been campaigning for a strong place in the directorate, has won a place for Professor Carlo Rubbia, Nobellist for his discovery of W and Z particles with his CERN proton-antiproton collider. Rubbia will chair a working group which will study "the long-range scientific and technological future" of CERN.

Meanwhile, after a meeting on the latest proton-antiproton collider results in St Vincent, in northern Italy, last week, physicists were surprised by the continuing discovery of events producing pairs of muons each carrying the same electric charge, but moving in opposite directions. A total of seven such events have now been seen in which the muons are not associated with "jets", the now-familiar signal for quark production and decay. Four of the events have no jets at all, and in five of the seven, strange quarks are produced (double the expected rate). No satisfactory explanation for these "like-sign dimuons" has been offered. Rubbia described these results and others as "a lot of good things cooking". However, "we must be prudent" in their interpretation. Robert Walgate

European research

Commission's new broom

Brussels

KARL-Heinz Narjes, the ex-U-boat officer who is now vice-president of the European Commission and responsible for industry, information technology and science, believes that the Commission's research policy is under test.

"If we fail this test, we will have a major political setback" said Narjes last week, sitting at pentagonal table at which commissioners representing the ten nations of the European Community regularly attempt to plan Europe's future.

A lawyer, and one of the founding fathers of the European Community, Narjes also firmly backs Esprit, the ambitious European programme of research in information technology started by his predecessor, Belgian Viscount Etienne Davignon. At the immense cost (by Commission research standards) of some £80 million a year, exceeding Europe's nuclear fusion research effort for example, Esprit attempts to knock European computer and electronics companies into some kind of coherent research policy and common standards.

Some major companies, such as Olivetti of Italy, have effectively spurned Esprit and believe they can dominate Europe with the help of US allies such as AT&T, while others continue to believe the programme can help (by forcing communication and joint standards). And for Narjes, "certainly Esprit is one of the tests". Moreover, "it is going very well", he claims. "Five hundred researchers are involved this year and there should be 2,000 next, and the first patent has already been applied for."

The setback in December when the European Parliament rejected the Commission's budget for 1985 will not much affect Esprit, the Commission claims, because the bulk of last year's money can be carried forward to 1985. On the other side of this coin, however, it seems the programme has been very slow to get moving.

Nevertheless, the Commission's political masters, the European Council of Ministers, had given a vote of confidence in Commission research programmes on 19 December with agreement in principle to support a substantial expansion of eight major programmes. Biotechnology, for example, will grow from its current budget of £6 million to £30 million a year. The Commission asked council for £2,000 million for 1984-87 and received a promised £1,400 million, still a substantial increase on current spending. "There's relief at being on the move again", said deputy research director-general David Hywell Davies last week, The test, said Narjes, is "whether we can manage the sums allocated".

But Narjes is already looking beyond this "first phase of solidarity" of European research, towards the "horizontal problems". These are the mobility of scientists and "the need to expose them to challenges".

Narjes sees no easy solutions. There are mundane obstacles such as national insurance, pensions, work for a spouse, differing qualification and education systems, security. Language itself is an "underestimated" problem, says Narjes. And it is politically difficult to argue that scientists should be treated as a special case, although the current political interest in using science to solve the economic crisis has given scientists an opportunity that they should seize. "We must make a major, long-term effort" for mobility, says Narjes. Does he have any real hope of success? "We have experience of hard negotiations. We can be 10 per cent tougher than the toughest member state."

Narjes also emphasized:

- The poor access of some non-English-speaking scientists to major US research journals.
- BRITE, a Commission programme to inject new technologies and science into small and medium-scale industries, which will be "a key programme if it succeeds".
- Agriculture, which takes 70 per cent of the Commission's budget "despite serious reforms", where the new biotechnology programme may help to give farmers new economic non-food products.
- The "budget needle", the eye of the needle through which Commission research projects must pass (the total budget still lies around 2-3 per cent of national research programmes). Here "we are seeking other sources" in the Commission, Narjes hinted.
- Big European research machines, such as the politically troubled European Synchrotron Radiation Source, for which the Commission might consider buying a "users' ticket" to distribute through Commission programmes.
- Coordination of Commission research programmes such as BRITE with space station research.
- Intra-Community communications, in science as in other fields, which form "one of the major European problems".

Robert Walgate

European cooperation in the air

BRITE, the European Commission's programme of Basic Research in Industrial Technologies for Europe, may have been oversold by its enthusiastic directors — but it has stolen a march on some other Commission programmes.

According to Dutchman Hendrick Tent, programme head, there has been "overwhelming reaction" to BRITE's invitation to industry and research bodies to participate in projects that will improve production techniques and provide the research base for new product lines in the next 5-10 years.

BRITE has been promised £70 million over four years, to be doubled by industrial contributions, but, like all the new Community research programmes, it still awaits final official approval from the council of ministers of the member states of the Community. This is expected any day now. But BRITE did not delay, having already called for "expressions of interest" to speed up the often bureaucratic process of calling for tenders and choosing and defining final projects. The BRITE team already has a good idea of what projects will be submitted, and has helped companies and researchers to prepare appropriate ideas and consortia, which contain partners from two or more member states and at least one industry. The programme has so far identified a need for projects in reliability and wear, laser technology, joining techniques, testing procedures, computer-aided design, electrochemistry, catalysis and particle technology.

Of the 3,037 expressions of interest received by 31 December, more than half were from industry, and more than a quarter from applied research organizations such as TNO from the Netherlands and the German Fraunhofer Gesellschaft. Fewer than a quarter came from academic institutions, although the proportion was higher in Britain. Britain made the most replies: around 800, compared with 700 from Germany, 500 from France, 400 from Italy, and 100 from Ireland. Some 21 applications came from the Community's newest member, Greece.

- **The European Commission's "stimulation" programme aimed at getting European academic laboratories together rejected 90 per cent of the 700 applicants for its first experimental phase. And it may have to do the same in 1985, the first year of full operations even though its support should increase fivefold (according to the 19 December council of ministers decision).**

So said one of the stimulation programme administrators in Brussels last week, explaining that the demand for European integration at academic level — and the concomitant funds — is enormous.

The stimulation programme should now get at least £33 million for 1985-89 (compared with just £4 million for 1983-84), of which £20 million is to be spent in the first two years, when ministers have encouraged the Commission to reapply for an increase. Sixty per cent of the cash will be spent on the twinning of laboratories, but some cash will also be put aside to run a European version of the "Gordon conference", where a select group of scientists can brainstorm in privacy.

Robert Walgate

NERC's corporate plan

SIR — The leading article (*Nature* 14 February, p. 515) on what you call the prospectus for the Natural Environment Research Council (NERC) contains a good breakdown of our present problems. Your conclusions do not follow. Having made the case for greater cohesion in the field of environmental research and touched on the history of why there is none, the answer is not as you suggest the dismemberment of NERC.

Early drafts of the corporate plan had the idea of submerging the research institutes in the new science divisions. Greater cohesion and flexibility may well come from abolishing the institutes, at the cost of more centralization. The plan published on 14 February was ambiguous. The absence from NERC of mainstream meteorological work is serious, but the corporate plan seeks to include work on climate. The main aim of the plan in its present form is to preserve university grants at a meaningful level. You rightly point out that in five years the universities will hardly notice the benefit. In contrast, in the same period, the funding to institute research could fall by up to 50 per cent and much long-term research will have been written off.

In the British Geological Survey (BGS) many staff feel a new home is necessary. They are committed to the need for continued survey but cannot carry out that task without an adequate level of dedicated funding. BGS finds no stability of finance within NERC and has been the target for an unfair share of cuts already. The proposal that BGS could find an umbrella similar to the British Antarctic Survey is as illogical as it is unlikely. No obvious slot exists for BGS and the present government would never sanction either the making of a new quango or the subsuming of 1,500 extra civil servants into an existing department.

The position of BGS outside central government gives a freedom with which only privatization might compare. The disadvantages of the latter course to the majority of staff and to the scientific needs of the community are obvious.

In the case of the Institute of Terrestrial Ecology (ITE), it is now untrue to say that any greater research links exist with the Nature Conservancy Council (NCC) than with any other government agency with interests in the biological environment. Scientists in ITE see a much wider role in the applied field of pollution studies and all aspects of land use, notably forestry and agriculture. The Ministry of Agriculture, Fisheries and Food and the Agricultural and Food Research Council have been slow to encompass sound ecological principles in answering environmental concerns. The House of Lords Select Committee report on agriculture and the environment (1984) came out in favour of much better liaison in research. Any return of ITE to a functional link with NCC would restrict the research scope and increase the accusation that the institute is simply an advocate of nature conservation. This denies the relevance of ecological work to a whole range of human activities. In any case research should be conducted away from the shackles of departmental policies.

Returning to the leading article of 14 February, your analysis of events leading to the NERC corporate plan was right, but the basic problem is the government's insistence on cuts. As its prescription may not change, it is best to look at what can be salvaged.

I have stated above why for dogmatic reasons the carving up of NERC will not suit the government either. It may be possible to persuade it to accept the proper integration of environmental science in the United Kingdom. In doing so it may get economies and take out some duplicated effort. To allow the fragmentation of NERC would make even more tenuous the links between disciplines and weaken research effort in key areas. This must not happen. Though we are against the planned 30 per cent cut in NERC manpower, we support the need for a properly directed and capitalized research council in the United Kingdom. It is our belief that reduction of institute strength and further fragmentation of research is not the way forward.

SIR — Given the now unavoidable association between the Natural Environment Research Council (NERC) corporate plan and the notion that a 3,000-strong workforce is to be reduced to 2,000, the choice of St Valentine's Day to announce the contents of such a melancholy document seemed at first sight inapposite until it is remembered that this feast day for romantics also commemorates a notorious massacre.

It may be about to commemorate another one — the sacrifice of the institutes on the altar of the universities. One of the principles underlying the plan and one that appears to have become axiomatic and therefore apparently beyond discussion (see *Nature* 31 January, p.340), is the transferring of institute resources to make up for the shortfall in government financial support for the universities. The plan is obviously modelled on the Mason report into the research councils which made canonical the notion that university research was more flexible and therefore better than the research of the institutes. Nowhere is the term "flexibility" defined or explained. It must be assumed in the absence of an explanation that flexibility in some way refers to an organization's response to the changing times we live in. In other words, it seems flexibility may mean how organizations respond to what has become almost the universal arbitrator — the market forces.

Terrestrial and fresh water ecology seem to have been earmarked for a large contribution towards the "Save the Universities Fund", yet the Institute of Terrestrial Ecology (ITE), for example, was born out of a not dissimilar transfer of funds a decade ago when a substantial percentage of its money was handed over from the Department of Education and Science with the Nature Conservancy Council (NCC) to the Department of the Environment, where NCC was to be a major customer of ITE and any other organization that chose to tender for NCC contracts. ITE has had to compete, and still does compete, with the universities among others for that money. If the universities are not able to obtain enough of that money through competition, are we to understand they will instead be given a proportion of, in this instance, ITE's funds instead? If this is so, how does this principle of flexibility operate other than to appear as a word whose context leaves it without meaning but with a use, namely that of a magic wand with which to shrink institutes.

In place of a more satisfactory explanation of the apparently fundamental concept of flexibility, perhaps there should be much wider consultation, not only on the "details" (*ibid*) but on the principles of the corporate plan.

Otherwise the more cynical employees of NERC institutes may just come to the conclusion that, since the institutes have no direct voice on council and the universities have many, what is being witnessed is not a "rational reconstruction" but something quite different.

Embryo research

SIR — The question "who can object to the proposition that there can be no such thing as a living being without implantation?" posed in your Opinion column (*Nature* 21 February, p.612) fails to address the objections to embryo research. In my mind the issue is not the point at which an embryo becomes a viable organism, but rather the point at which a unique potential member of our species is created. There can be no objections to the proposition that this takes place at fertilization.

An appeal to embryologists

The British House of Commons seems bent on passing a bill to prevent some kinds of research. Here is a way in which embryologists and geneticists can help themselves and even help defeat the bill.

MR Enoch Powell's already famous bill to prevent the use of fertilized human embryos for any other purpose than the treatment of infertility seems to have carried the British House of Commons with it. The substantial majority for the second reading of the bill two weeks ago, endorsement of the principle, is an embarrassment for the British government, properly anxious to produce a comprehensive piece of legislation to deal with the problems defined in last year's report from the Warnock committee, but which should also have seen the danger that its plans could be so easily undermined.

What the House of Commons seems not to appreciate is that it has embarked on an unprecedented and dangerous course, the outright banning of certain kinds of research. Its intention, following Mr Powell, is that there should literally never be in Britain even the most sober and well-intentioned investigation of human embryos.

But why should research be sacrosanct, especially when it flatly conflicts with what seems to be an absolute moral principle? This is what the 238 Members of Parliament who voted for the Powell bill were asking two weeks ago. What the scientific community must now recognize is that, while there may be arguments about the force of the moral principle, there is very little chance that this substantial body of opinion in the House of Commons will simply melt away. The practical task is somehow to persuade a large group of sensible people, who must constitutionally be supposed to represent a comparable body of opinion in the general population, that some other course of action than Mr Powell's bill will meet their need.

The starting point must be that research is not sacrosanct. There are already many fields in which investigators do not enjoy untrammelled freedom to do what they like. In most countries, experiments with animals are quite properly regulated with the objective of minimizing the pain that may be suffered in the best-designed experiments. Here the guiding principles are that animals, whose lives are not protected as are those of human beings, must nevertheless not suffer needlessly, which is a goal in its own right but which also protects the investigators concerned from debasement. In genetic manipulation and in work with dangerous pathogens, investigators are free to follow their interests only if they conform with guidelines designed to protect the safety of other people. In most countries, fetal material (as obtained at abortion) can be used, but only with seemly consideration for its source. More to the point, even investigations in which people are the experimental subjects are allowed, but only under the strictest criteria, among which pride of place is taken by the doctrine that the subject must understand what is proposed and must appreciate what risks may be involved. The plain fact is that there are already many fields of research which raise difficult moral problems. In no case has it yet been thought necessary to institute an outright ban. Regulation has been thought sufficient.

The reasons why an otherwise sensible legislature has on this occasion departed from precedent must be understood more clearly. Part of the explanation lies in the title of Mr Powell's bill, the "unborn children (protection) bill". Logician that he is, Mr Powell's argument against regulation rather than an outright ban is easy to predict: embryos are people or potential people who, because of their condition, are unable to give their informed consent. The best hope of winning a better piece of legislation is the likelihood that not many members of the British House of Commons will share this extreme position.

Even a superficial reading of the debate on 15 February in the House of Commons will show that the supporters of the bill span as wide a spectrum of opinion as would be expected. Mr Powell's acknowledged "deep and instinctive" revulsion from investigations of human embryos was widely shared, while many participants in the debate volunteered the opinion that "scientists must be stopped from playing God". The missing ingredient in the debate was the clear statement of what exactly are the benefits of investigations with human embryos. That is not surprising, for as yet there have been no such investigations.

The most common misapprehension seems to have been the almost entire lack of an understanding of what may be meant by research with human embryos. Within the scientific community, it is too easy to suppose that the implications are generally understood. But the chances are that, for many purposes, mere observation (with the help of a microscope) would suffice. Given the general interest in the early differentiation of embryos, it might also be necessary to separate early embryos into individual cells, perhaps so as to understand the circumstances in which totipotency is lost (but those are investigations on which work with other mammalian embryos might suffice). The immunology of the early embryo, and questions of teratogenicity, might involve adjusting the chemical environment of an embryo *in vitro* by the addition of identified substances, may of them naturally occurring. In all kinds of investigations, it would be necessary to be able to dissect an embryo after some fixed period of development, perhaps so as to learn something about its genetic structure. Compared with the more lurid suppositions of what the new opportunities in human embryology constitute — schemes for making literally artificial human beings and the like — this is all dull and almost pedantic stuff. Indeed, except in relation to the technology of *in vitro* fertilization, there seems at present something of a dearth of serious proposals for investigations that would make sense.

Accordingly, those with an interest in these opportunities (and in seeing the debate about the Powell bill take a measured course) are invited to take part in an experiment. The intention is to discover what kinds of investigations with human embryos would, in present circumstances, be carried out. Those willing to participate are asked to send to the editor (in London, in an envelope marked "Embryo Research") a synopsis of a proposed investigation with human embryos, giving a succinct account of the objectives, the reasons for expecting these to be attainable, a brief account of the procedure to be followed (together with an estimate of the numbers of embryos required, controls included) and an explanation why the use of human as distinct from other mamalian embryos is necessary.

Synopses received in the *Nature* office within one month of the date of this issue and judged suitable for the purpose will be sent to a panel of referees composed along the lines recommended by the Warnock committee. Opinions will be solicited from lay people as well as from researchers and physicians. Submissions as such will not be published, but (with the agreement of the authors) the gist of each proposal will appear together with the opinions of all the referees. Those whose submissions are dealt with in this way will be asked to nominate someone (possibly themselves) to receive a copy of *Nature* free for the year ahead. The outcome of this experiment may be to put the Powell bill in perspective. □

Condensed matter and planetary science

First-order phase transitions between amorphous ices

from J.P. Poirier

WHAT seems to be an unprecedented case of a first-order phase transition between amorphous solids is reported on page 76 of this issue. Since it concerns amorphous ices, it has some specific importance for the understanding of icy bodies in the Solar System and for the cryopreservation of biological samples. But it also has general implications for the physics of disorder and for a range of solids that might exhibit transitions between amorphous forms.

Amorphous solids can be obtained by a variety of methods: direct condensation of gases onto a cold plate; quenching of liquids through the glass-transition temperature; and intense irradiation by energetic particles or the impact of high-velocity projectiles. Unlike crystals, amorphous solids are disordered in structure, although not as chaotic as was once thought; they lack crystalline order, but according to the way they are prepared and to the nature of their chemical bonding, different kinds of disorder are found. The physics of ill-condensed matter is an active field of research, in which theoreticians and experimentalists alike are busy describing or predicting the structure of liquids, glasses and all sorts of amorphous solids.

The amorphous ices are of particular interest in two respects. First, they may be present in cometary nuclei, interplanetary dust and ring particles, and in the interior or at the surface of the satellites of the giant planets. Water has at least nine crystalline polymorphic varieties, some of which are metastable far away from their stability field. Second, by the use of cryoprotectants to promote the formation of amorphous rather than crystalline ices, living cells are protected against death caused by the volume expansion that accompanies the normal freezing of liquid water into the common form of ice, ice I. One cannot, therefore, overemphasize the interest of two papers from O. Mishima, L.D. Calvert and E. Whalley of the National Research Council laboratories in Ottawa, Canada. In the first (*Nature* **310**, 393; 1984), they report the preparation of amorphous ice by 'melting' crystalline ice I under pressure at temperatures below the glass transition of water; now, on page 76, they report the phase transition between this and another variety of amorphous ice.

The melting point of ice I decreases as pressure increases, but at low temperature and high pressure other crystalline phases become more stable than liquid water or ice I. The melting curve of ice I can, however, be extrapolated in the stability field of ice VI, showing that, in principle, ice I could 'melt' at 77 K and 10 kbar. By compressing ice under these conditions, Mishima *et al.* obtained an amorphous phase, which persists in metastable state on removal of the pressure. The density of the new phase is consistent with the extrapolated density of water under pressure. At atmospheric pressure and 77 K, the amorphous phase has a density of 1.17; it does not have the same X-ray diffraction pattern as the amorphous phase prepared by quenching water by jet freezing (Mayer, E. & Brüggeller, P. *Nature* **298**, 715; 1982). On heating to 117 K it transforms, with heat evolution, to a less dense amorphous phase resembling the form obtained by condensation of vapour onto a cold plate at temperatures above 80 K. There is clearly a rich variety of amorphous structures and their relationships have to be investigated.

In their paper, Mishima *et al.* report that compression of the low-density (0.94) amorphous ice obtained by vapour condensation produces the same high-density phase as they obtained by 'melting' ice I under pressure. The new and interesting point is that the transition, which occurs sharply at 6 kbar, seems to be the first reported case of a first-order transition between amorphous solids.

The theoretical possibility of phase transitions between amorphous solids or quenched liquids with differing packing structures has been considered by F.H. Stillinger and T.A. Weber (*Science* **225**, 983; 1984). At a meeting last year on Ices in the Solar System (see *Nature News and Views* **308**, 692; 1984) E. Mayer and R. Pletzer reported that vapour condensation onto a cryoplate provides two varieties of amorphous ice: a low-density porous solid when the flow is supersonic and a glass-like, dense non-porous solid when the flow is broken up by a baffle. Their hypothesis about the structures of these phases implies polymorphism for the amorphous ices. It is not yet clear whether the dense amorphous ice produced by Mishima *et al.* is the same as that of Mayer & Pletzer or that reported to be formed by condensation of vapour on a plate at temperatures lower than 10 K (Narten, A.H., Venkatesh, C.G. & Rice S.A. *J. chem. Phys.* **64**, 1106; 1976).

Clearly the evidence for first-order phase transitions between amorphous structures opens exciting new vistas in the physics of disorder, although one may, perhaps, shudder at the thought of the pressure/temperature phase diagram of water, with its superposition of many stable and metastable crystalline phases, being further complicated by the addition of boundaries

Riddle of reflections in the water

WHAT is the shape of the image of the mast of a sailing ship seen reflected in the water? Suppose the surface of the water is wavy, but not to the extent of creating sharp wave-crests (that is, the gradient is nowhere discontinuous). Of course, you will say, the image of the mast will be 'wiggly'. But will there be pieces of mast seen disconnected from the wiggly main image? Presumably yes, since there is no reason why there should be not be an occasional area of water surface off to one side and so inclined that it would throw light from the mast to the observer, and at the same time there might be no area in between that would do likewise.

What shape will such a disconnected piece of the mast image have? In particular, will there be 'ends', where the mast image appears broken? The picture on the cover of this week's *Nature* gives the answer. Disconnected pieces are closed loops. Why?

Here is a simple way to visualize the situation. Suppose instead of the mast we have a vertical line dividing a black area on the left from a white area on the right, each such area stretching out indefinitely far to left and right respectively, as well as upwards. The image area in the water on the right-hand side will then be largely white, but it may contain some black patches. Again, it is clear that they can be disconnected, meaning that they are wholly surrounded by white, since there can be an occasional patch of water surface at such an inclination that it looks into the black side of the object plane. What is the nature of the edge of such a black patch?

We may choose two closely adjacent points in the image, one within the black patch and the other just outside, in the white. Since the water surface has no discontinuities of gradient, the two adjacent rays must come to adjacent points in the object plane. But the only places where black and white areas are adjacent is on the dividing line. Since this consideration applies to every pair of points straddling the edge of our black patch, it implies that its entire edge must image a part of the dividing line into a closed loop, wherever a disconnected patch occurs. The appearance of the sailing ship mast follows from the same consideratons.

There is one additional condition required for all this to be true. The surface of the water must not anywhere be inclined to the horizontal as steeply as the line of sight from the observer, so no area of the surface is shielded from view.

Thomas Gold, Cornell University.

between metastable amorphous phases. The consequences extend further, as Mishima, Calvert and Whalley point out: other solids, which melt with a decrease of volume (like germanium, silicon and boron nitride), might exhibit several amorphous structures, some of them possibly resulting from 'melting' under pressure at low temperature.

Water vapour in the outer reaches of the Solar System that is condensed as amorphous ice and small bodies, like the particles in the rings of Saturn, the nuclei of comets and small icy satellites, may still contain a large proportion of (presumably) low-density amorphous ice (Smoluchowski, R. *Science* **222**, 161; 1983). Meteoritic impacts on the surface of icy bodies may also form amorphous ices by direct amorphization due to the shock, reversion of shock-produced high-pressure phases, or recondensation of vapourized water. It has been suggested that the heat evolved during the transition from amorphous ice to cubic ice I at 153 K provides the supplement of energy needed to melt and resurface Saturn's satellites Enceladus and Dion (Klinger, J. *Nature* **299**, 41; 1982) and alters the heat and mass balance of comets (Klinger, J. *Science* **209**, 271; 1980). As pointed out by Mishima *et al.*, we now have to take into consideration the possibility that low-density amorphous ice might transform into dense amorphous ice during accretion of the larger icy satellites (like Ganymede, Callisto or Titan) and then retransform exothermally into a variety of amorphous structures as the temperature increases inside the planet. □

J.P. Poirier is at the Institut de Physique du Globe de Paris, 4 Place Jussieu, 75230 Paris Cedex 05, France.

Evolutionary biology

A new phylogeny for Darwin's Galapagos finches

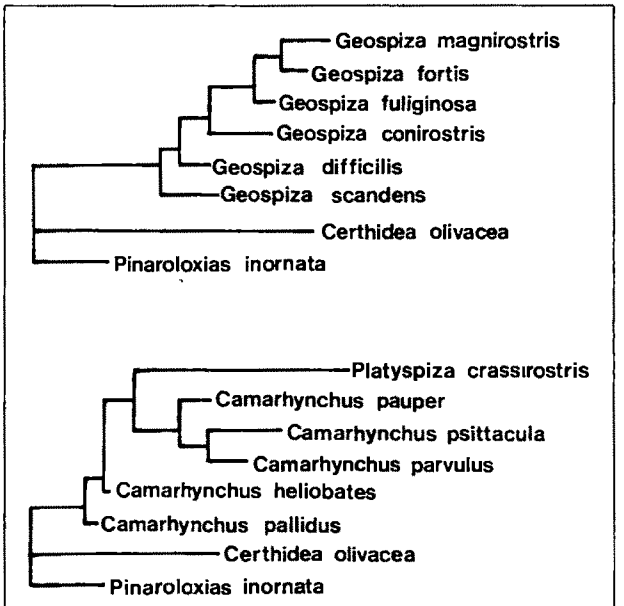
from Paul H. Harvey

EVOLUTIONARY biologists owe it to the memory of Charles Darwin to produce a phylogeny of his famous Galápagos finches. Schluter has produced one such phylogeny in a recent paper[1]; more importantly, he constructs it using a new method which assumes that natural selection alone has caused changes in morphology among the different finch species. Darwin might have appreciated that.

There have been two previous attempts to describe the relationships among the various finch species. The first, by Lack[2], was a qualitative assessment based on comparative morphology. The second, by Yang and Patton[3], used electrophoretic variation of proteins. Differences between the two estimates may result both from the different databases used and the failure to base the analyses on suitable models of evolutionary change.

The justification for Schluter's new analysis comes from recent ecological studies on Darwin's finches by Grant and his colleagues[4,5,6]. Their work leads to the conclusion that morphological variation among the finches is largely the result of differentiation by natural selection. But genetic constraints must also be taken into account if an evolutionary tree is to be derived on the assumption that differences between species are purely a result of natural selection. Genetic variances and covariances among the characters used in the analysis are the two relevant genetic constaints[7]. If genetic variances are high then characters are more susceptible to change by natural selection. If two characters covary positively then more selection is required to increase one and decrease the other than if the genetic covariance were to be negative. Lande[8] produced a quantitative genetic model that takes these factors into account and Schluter has adapted the model in order to estimate the total net force of natural selection that has led to differentiation among Darwin's finches. His analysis is based on phenotypic variances and covariances among eight measures of wing, tarsus and mandible size. The variances and covariances among the characters are similar within ground finches and within tree finches but differ between the two groups, so analyses were performed separately.

Phenotypic measures do not necessarily reflect underlying genetic trends but, fortunately, it appears that they do in the case of Darwin's finches. A recent genetic analysis of variation in the tree finch *Geospiza fortis*, which investigates five of the eight characters used by Schluter, shows that the five phenotypic and genetic variances correlate with a value of 0.98, while the ten covariances have a 0.99 correlation[9]. This allowed Schluter to substitute phenotypic estimates for the genetic variances and covariances.



Schluter includes the warbler finch *Certhidea olivacea* in both the ground finch and the tree finch analyses because this species probably branches off prior to the division of the two groups; its omission from the calculations does not change either of the phylogenetic trees. Like Lack before him, Schluter incorporates data from Cocos Island's putative warbler finch *Pinaroloxias inornata*.

The new evolutionary trees, shown in the figure, are similar to Lack's, but there are some differences; the ground finches *Geospiza difficilis* and *G. scandens* appear more closely related than in Lack's analysis, while the tree finches *Camarhynchus pallidus* and *C. heliobates* come close to the ancestral condition according to Schluter, yet are highly modified forms according to Lack. Yang and Patton's electrophoretic analysis resulted in a tree similar to Schulter's, although it is based on only eleven of the fourteen species used by Schluter and Lack.

The new method differs from standard cladistic techniques[10] in measuring branch lengths of the phylogenetic trees, while quantitative variation in the original characters is more effectively incorporated into the analysis. Equally important is the use of distance measures which are based on an explicit genetic model, many of the assumptions of which seem reasonable in the present case. □

Stellar structure

Beginnings of asteroseismology

from Douglas Gough

THE science of determining the internal structure of stars from the properties of dynamical oscillations, known as asteroseismology, has only recently become a possibility. Solar five-minute oscillations[1,2] have already yielded important information about the structure and composition of the Sun. Now similar five-minute oscillations have been reported for three distant stars[3-5]. Interpretation of the data from two of these[3,4] provides few surprises, but the third[5] seems to be anomalous and may pose a new and interesting problem to stellar astronomers.

The significant breakthrough came when Isaak *et al.*[2] discovered that they could detect the five-minute oscillations from the Sun in spatially unresolved whole-disk Doppler data. Some spatially resolved data[1], available for several years, had convincingly demonstrated that the five-minute oscillations are a manifestation of resonant acoustic waves trapped beneath the solar photosphere. Although important conclusions about the structure of the Sun's convection zone have been drawn from these observations, such detailed information cannot be obtained from other stars. Whole-disk observations, on the other hand, use light integrated from the entire visible surface of the Sun, which is just what one is forced to do when observing the distant stars.

Oscillations of ordinary stars have the spatial variation of spherical harmonics. For each value of the degree l of the harmonic, there is a sequence of resonant acoustic modes that are labelled with the integer n. These correspond to the fundamental tone ($n = 1$) and the overtones (of order $n-1$) of a musical instrument. On the whole, n is the number of spherical nodal surfaces inside the star, and is a measure of the vertical component of the wave number of the acoustic wave; the horizontal component of the wave number is approximately l/r, where r is the distance from the centre of the star.

A resonant acoustic mode can be considered as an appropriate superposition of many propagating sound waves with the same frequency. Because temperature, and hence sound speed, increase with depth inside a star, downward-propagating waves are refracted back towards the surface. Waves with periods longer than about three minutes, in the case of the Sun, are also reflected by the highly stratified material immediately beneath the photosphere. When l/n is large, the waves are refracted quickly, and are thus confined to a thin outer shell immediately beneath the stellar surface. Its thickness is about $(2n+3)\,R/l$, where R is the radius of the star. When l/n is small, the waves propagate nearly vertically, and penetrate to the core of the star. For the Sun, it has been possible to infer the variation of the sound speed through much of the interior[6] by analysing five-minute oscillations with a wide range of l/n, with a technique bearing some resemblance to that used by particle physicists to infer potentials from scattering experiments.

Whole-disk observations are sensitive to only the lowest values (0-3) of l, and consequently cannot access a very wide range of l/n. Nevertheless, in principle one can still gain useful information about the stellar interior. The density and pressure througout the star can be expressed in terms of linear combinations of oscillation eigenfunctions, with coefficients that depend in a calculable way on the eigenfrequencies, rather like expressing a function as a Fourier series. By measuring oscillation frequencies one might therefore hope to determine how the star is stratified. Indeed, using artificial data it has been demonstrated that if the frequencies of a substantial number of appropriate low-degree solar oscillations are known, the interior pressure and density distribution can be inferred quite accurately, provided the variation of the adiabatic exponent is unimportant.

Unfortunately real data of that kind are not yet available. In the case of the Sun, the acoustic modes are excited to an amplitude great enough to have been detected only in a frequency range between about 2 mHz and 4 mHz (though there is now evidence that another class of modes—the gravity modes, whose restoring force is provided by buoyancy—has also been observed). These modes are quite high overtones, with n between approximately 12 and 33, and by themselves are inadequate for describing the interior stratification—without the lowest sinusoids in a Fourier expansion one cannot in general obtain a good representation of a function. Nevertheless, one can draw some useful conclusions.

The cyclic frequencies ν of low-degree acoustic modes satisfy

$$\nu = (n+\tfrac{1}{2}l+\alpha)\nu_0+\varepsilon(n,l),$$

where α and ν_0 are constants and $\varepsilon/\nu = 0\,(n^{-2})$ when n is large. With the exception of only the lowest-order modes, the frequencies form groups with alternate odd and even l, which are approximately uniformly separated by $\Delta\nu = \frac{1}{2}\nu_0$. A moderately resolved power spectrum of oscillation data should reveal this spacing. It establishes the value of the base frequency ν_0, which is half the reciprocal of the time taken for sound to travel from the star's centre to its surface.

The whole-disk observations first reported by the Birmingham helioseismologists[2] clearly exhibit this property in the oscillations of the Sun, with $\Delta\nu$ of about 67.8 μHz. Now we have the first indications of similar oscillations in other stars. By combining photometric observations of the Ap star HR 1217 over the same time period from South Africa and Chile, Kurtz and Seeman[3] have found six approximately uniformly spaced frequencies near 3 mHz. Fossat *et al.*[5] and Noyes *et al.*[4] also have evidence for uniformly spaced frequencies of α Centauri A and ε Eridani, respectively.

The mean frequency separation measured by Kurtz and Seeman is 34.7 μHz. As Shibahashi[7] has pointed out, the situation is likely to be similar to that of the Sun: modes of both odd and even degree are probably present, so the observed spacing $\Delta\nu$ approximates $\frac{1}{2}\nu_0$. Computations by Christensen-Dalsgaard[8] show that on the zero-age main-sequence, $R\Delta\nu$ is roughly constant. (Main-sequence stars, like the Sun, are at the stage of their evolution where they are powered by hydrogen fusion in their cores). In other words, all zero-age main-sequence stars have the same harmonic mean sound speed. If evolutionary effects are small we can deduce that HR 1217 has about twice the radius of the Sun, a value typical of an Ap star.

The observations of α Centauri A and ε Eridani are particularly interesting because these stars are quite similar to the Sun. Their oscillation amplitudes are much smaller than those of HR 1217, so more sensitive observing techniques were required. Fossat *et al.*[5] observed variations in the intensities at fixed frequencies on the red sides of the Na-D spectrum lines, with the intention of detecting Doppler shifts. Noyes *et al.*[4] observed variations in the profiles of the Ca II-H and -K chromospheric emission lines. Both found evidence for discrete oscillatory modes. After a certain degree of filtering, it was deduced that the envelope of the power spectrum for α Centauri has a broad hump centred at about 3 mHz, like that for the Sun. In neither case was the power spectrum clean enough to identify individual modes unambiguously, so there is room to doubt the interpretation of the data. Nevertheless, the power spectrum of the power spectrum for α Centauri A[5] and the autocorrelation of the power spectrum for ε Eridani[4] both suggest a periodicity in the power, at frequency separations of 81.3 μHz and 86 μHz, respectively.

The approximate constancy of $R\Delta\nu$ found by Christensen-Dalsgaard[8] for the zero-age main sequence is also a property of main-sequence stars with the same evolutionary age, though the value of the constant changes as the stars evolve. The homologous scaling $R^{3/2}\,\Delta\nu$ = constant is approximately satisfied by a star during its central hydrogen-burning phase, even though the changes the star undergoes are not strictly homologous.

As pointed out by Noyes *et al.*[4], their observations of ε Eridani appear to be con-

sistent with these scaling laws. Judged by its strong Ca II emission, the star seems to be younger than the Sun, and Lacy[9] has established that $R/R_\odot = 0.81 \pm 0.08$, where $R_\odot$ is the present radius of the Sun. Since $R\Delta\nu/R_\odot$ is calculated to be 72.5 μHz for the zero-age main sequence, and $\Delta\nu$ is about 68 μHz for the Sun now, one would expect $\Delta\nu$ for ε Eridani to be 84-90 μHz. This is indeed the case.

The observations of α Centauri A do not conform to this pattern. The star is a member of a binary system and is known to have a mass of 1.1 $M_\odot$. According to Christensen-Dalsgaard and Frandsen[10], $\Delta\nu$ should have been 71 μHz when such a star was on the zero-age main sequence; its radius should have been 1.03 $R_\odot$. Since $\Delta\nu$ is now 81.3 μHz, one would deduce from homologous scaling that R is approximately 0.94 $R_\odot$. Having a higher mass and apparently a lower radius than the Sun, at first sight α Centauri might therefore also be thought to be younger because, according to the theory of stellar evolution, the radii of late-type main-sequence stars increase with both mass and age. But the observed $\Delta\nu$ appears to imply that α Centauri A has shrunk. This contradicts observation as well as theory, since Blackwell and Shallis[11] find from the infrared magnitude and a knowledge of the distance of α Centauri that $R/R_\odot = 1.23 \pm 0.04$. Moreover, Flannery and Ayres[12] conclude, from matching the theory of the evolution of the companions of the binary system with all the available observations, that α Centauri is probably older than the Sun. Either the oscillation data have been misinterpreted or the structure of α Centauri A is quite different from expectations.

More highly resolved measurements of the oscillations will have to be made in order to decide between these possibilities. It would help to have several days of almost continuous data, which can be obtained by observing from two or more sites widely separated in longitude over the same period, as has already been done for HR 1217 and the Sun[3,13]. Alternatively the stars might be observed from Antarctica or from space. From such data, it may also be possible to measure the small quantity ε in the dispersion relation, which separates the frequencies of modes with like $n + \frac{1}{2}l$ but different l, and which measures conditions close to the centre of the star[14]. This would give us direct information about the stratification of the energy-generating core of a distant star, an exciting prospect indeed. □

Scrapie

Perspectives on prions

from Colin Masters

AFTER decades of research into a group of 'slow virus' diseases, Stanley Prusiner and his collaborators have published a continuing series of papers identifying a new type of infectious particle—the prion (for proteinaceous infectious particles). The remarkable resistance of the prion to chemical and physical procedures that attack nucleic acids, and its small size (reportedly 100 times smaller than the smallest virus) have directed attention towards the possibility that the prion consists of protein without associated nucleic acid and that its replication proceeds via protein-directed protein synthesis—a situation which would be without precedent in biological science and contrary to the dogma that genetic information invariably flows from nucleic acids to proteins. Consequently, it is not surprising that the research (see refs 1 and 2 for reviews) has given rise to a great deal of speculation on the nature of prions, on the alternative possibilities of their replication, and on their significance in relation to several chronic degenerative diseases of humans. The potential ramifications make it worth assessing the status of prion research.

The research may be traced back to the 1950s when the first intensive studies began in the highlands of New Guinea into the strange degenerative condition known as kuru[3]. The dramatic nature of these findings (kuru was found to be transmitted by the cannibalistic habit of eating uncooked brain) stimulated interest in scrapie, a related disease of sheep and goats which can be produced experimentally in small laboratory animals. Scrapie researchers have coped with many formidable technical difficulties but after experimental models of scrapie were produced in mice and hamsters in the 1960s, several groups began to purify the causative agent[2,4,5], which was presumed to be a virus. It became apparent that the agent was firmly associated with cell membranes and could only be released by quite drastic treatment. Proteases, detergents and denaturants were commonly used in purification and it was the remarkable stability of the infectious agent to these substances, together with its resistance to nucleases and ultraviolet irradiation that led to a view that the scrapie agent may not be a virus at all.

Much of the data pointed to the importance of the protein content of the particle for scrapie infectivity. This, together with the continued failure to demonstrate the existence of a scrapie nucleic acid, led to the suggestion that the protein may either code directly for its own replicative synthesis or induce genes of the infected animal to do so for it[1]. Subsequently, similarities between prion aggregates in tissues and the amyloid plaques that are features of several human diseases were pointed out by Prusiner, who suggested the involvement of prions in a wide range of conditions including senile dementia, multiple sclerosis, rheumatoid arthritis, Parkinson's disease, diabetes, lupus erythematosus and cancer[2]. Clearly, if these postulates are substantiated, they will have momentous implications for biomedical science.

What remains to be done then before this critical and highly contentious situation is finally clarified? At present, quite severe criticisms of major elements of the prion hypothesis are still appearing in the scientific literature[6,7]. Several authors have pointed to the fact that much of the evidence is negative in nature—never a fully satisfying situation for the scientist. Much of the data on the physiochemical characteristics of the infectious agents in tissues is difficult to interpret because of the crudity of the extracts. It has been suggested, for example, that the organism's extraordinary resistance to inactivation, which has led to much of the present speculation on this new life form, may not be a feature of the overall population of particles but rather is limited to small subpopulations. It has, moreover, been claimed that when conventional viruses are suspended in tissue homogenates, they too can provide examples of resistant populations and insensitivity to virucidal agents. The deduction that the scrapie agent has a sub-viral size has also been questioned, and it has been pointed out that there is good *a priori* evidence that the scrapie agent has a nucleic acid genome, even if direct biochemical evidence is lacking. Finally, it has been argued that if all the scrapie agent has to do is be replicated by host enzymes and interact with the host in strain-specific ways to produce disease, its nucleic acid could be unusually small and difficult to detect.

Clearly, it would be possible to resolve most of the outstanding questions if the infectious agent were available for examination in purified form. It is, therefore, encouraging to note that rapid progress is being made in that direction. It

has been established that the bulk of the protein in the scrapie agent consists of a single molecular species (called PrP, for prion protein)[8]. PrP is a glycoprotein, of apparent relative molecular mass of 30,000, and has been highly purified and partially sequenced. When the complete sequence has been determined, it will be possible to synthesize the same sequence and test whether it has the same biological action as the natural agent. Only then will it be determined with certainty whether prions are both infectious and devoid of nucleic acids. When the synthetic molecule is available, antibodies to it could also be produced for titration of scrapie, and synthetic sequences of the corresponding gene could be constructed and used to investigate both the function of the PrP gene in the cell and the presence of the PrP gene in the host genome. It will also be important to determine the amino-acid sequences for myeloid proteins and compare them with PrP to establish the exact connection between amyloid plaques and the infectious agent.

The imminent resolution of many of these questions heralds an exciting era of biomedical advance. An intriguing area of scientific curiosity which has been impeded by forbidding technical problems has been transformed into a rapidly progressing and productive area of contemporary research. Already, the the immunological evidence available appears to provide support for the view that the amyloid plaques in the brains of scrapie-infected animals and humans with Creutzfeldt-Jakob disease are composed of arrays of prion proteins[9]. Soon we should know for certain whether prions do indeed represent a revolution in molecular biology and medicine, or if they are another manifestation of the complexity of interpreting molecular behaviour in the cellular microenvironment. □

Immunology

Control of T-cell development

from Roland Scollay

OUR understanding of the control of the proliferation and early differentiation of T lymphocytes in the thymus gland is hazy, to say the least. Yet the thymus supports a large population of dividing cells[1] and about 30 per cent of its lymphocytes are replaced every day[2]. The hope that either one of the thymic hormones or interleukin-2 (IL-2) — a potent growth factor for mature stimulated T lymphocytes — would turn out to be the key factor for proliferation of the blast cells from which T lymphocytes are derived, has not been realized[3,4]. As a result the notion has arisen that growth factors are less important for proliferation than the interaction between blast cells and other non-lymphoid cells of the thymus. But two papers in this issue[5,6], showing IL-2 receptors to be on a subset of cells in the thymus, come as a faint ray of hope that IL-2 is the key.

About 80 per cent of the blast cells (15 per cent of all cells) in the murine thymus are the parents of the major population of small thymocytes in the cortex of the thymus. On their cell surfaces, they carry two antibody-defined markers associated with functional T lymphocytes[7]. The markers are Ly2 and L3T4, so the cells are classed 2^+4^+. Most of the other blast cells (about 3-5 per cent of all thymocytes) are 2^-4^-— that is they express neither Ly2 nor L3T4 and are generally felt to be precursors of, presumably, both cortical and medullary cells[7]. These 2^-4^-blasts are the predominant population in the embryonic murine thymus from day 12-16 or 17 of gestation, an observation which lends credence to their role as precursors[8].

It is on these 2^-4^-blasts that receptors for IL-2 have now been demonstrated. Ceredig *et al.*[5] use an antibody to the IL-2 receptors to show that about half the 2^-4^- blasts in both embryonic and adult thymus express the receptor, although those from the adult thymus (embryonic not tested), are slightly fewer in number and lower in affinity than those found on mature lymphocyte (Con A) blasts. They also demonstrate that the cells with IL-2 receptor are scattered throughout both the cortex and medulla of the thymus. Using different monoclonal antibodies, Raulet[6] finds a very similar distribution of the receptor on adult and embryonic blasts but, unlike mature lymphoid blasts which respond vigorously to IL-2, neither population of thymic blasts responds to IL-2 unless an additional stimulus (Con A) is added.

These data are relevant to a number of issues. First, it has generally been felt that 2^-4^-blasts are mainly confined to the outer cortex of the thymus, even though blasts in general, although more concentrated in the outer cortex, are widely distributed. The data from Ceredig *et al.*[5] show that the IL-2 receptor-positive 2^-4^- blasts are also widely distributed. Whether 2^-4^-cells occur in the medulla is still unclear, since it has not been established whether all the IL-2 receptor-positive cells are 2^-4^-, as both papers point out.

The second but related point concerns the heterogeneity of 2^-4^-cells. Other work shows that they are not a homogeneous population. Are receptor-positive and receptor-negative cells precursors for two pathways or lineages, or are they sequential stages of one (or more) pathway? The new data open up several interesting lines of experiment to answer such questions.

The third issue concerns the role of the receptor in cell differentiation. The receptors on thymic 2^-4^- blasts have relatively low affinity for IL-2, which perhaps accounts for the fact that the cells are not well stimulated by IL-2 alone. Unfortunately, there is no affinity data for the embryonic cells, which respond even less well to IL-2 alone, so it remains unclear whether this reflects a real difference in receptors or a response by the unkilled mature cells in the adult 2^-4^-preparation.

Nonetheless, the presence of the receptor in the embryo is important in interpreting the adult data. In general, immunologists associate IL-2 receptors with antigen- (or mitogen-) activated T lymphocytes and with mature cells that produce IL-2. The fact that before day 16 the embryo seems not to express antigen receptors[9] and that neither IL-2 producing cells nor cells of the usual (mature) IL-2 producing phenotype are detectable until several days later[8], suggests that the receptor on 2^-4^- cells may be operating quite differently from those on mature T cells. Indeed, the whole process within the thymus must be quite different, since the major, rapidly-dividing 2^+4^+ blast population, which presumably derives from the 2^-4^- blasts, is completely lacking the receptor[5,6] unlike any other population of activated lymphocytes. Perhaps we should not be unduly influenced by our knowledge of the activation process in mature cells in considering the significance of the IL-2 receptor on thymic cells and its presence on cells should not necessarily be taken as evidence that they are stimulated by antigen.

Some evidence of IL-2 production in the embryo would go far to establishing the relevance of the receptor. Without this, I find it too early to speculate on the receptor's role. But clearly, these experiments and the rapid increase in knowledge of the T-cell receptor brings us closer to an understanding of the secret workings of the thymus. One day a cocktail of factors added to a single T-cell precursor may allow us to observe the complete process of T-cell development in a test tube; but it may yet turn out that cell-to-cell interactions are essential. □

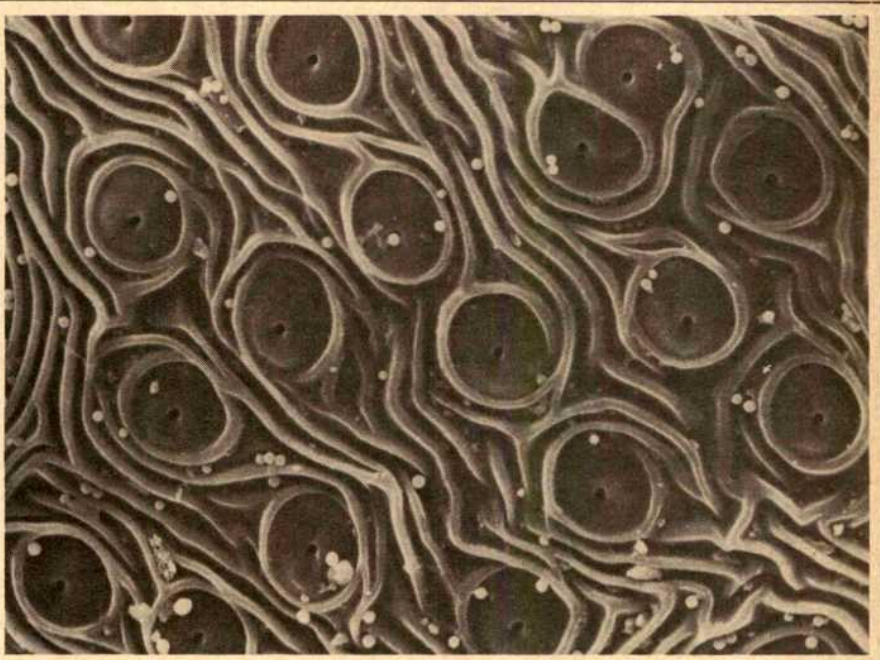
Periodic extinctions

Cratering theories bombarded

from Paul Weissman

ONE of the first lessons for any young scientist is how to limit research to a finite task. "All of us", wrote geophysicist E. C. Bullard in 1960, "dig our own small specialized holes and sit in them". For those scientists who venture out of their holes, few problems today are so quick to bring on feelings of agrophobia as the study of biological extinctions of species on the Earth. Once relatively confined to the planet, the various aspects of the extinction problem have reached out first into the Solar System, and now to the Galaxy surrounding it. To explore these new horizons, astronomers and other concerned scientists met in January* to examine, and heatedly debate, the possible interactions between the Earth, the Solar System and the Galaxy.

The problem of biological extinctions was once the sole province of the palaeontologists and biologists who studied the fossil record of the rise and fall of species. Then, in 1980, physicist Luis Alvarez and his geologist son, Walter, along with colleagues, suggested that the Cretaceous-Tertiary extinction 65 Myr ago was associated with the impact of a 10 km diameter asteroid. They found a strong concentration of iridium in the boundary clay coincident with the extinction. Iridium is very rare in the Earth's crust, most of it having gone into the core when the planet differentiated.



A second expansion of interest in extinctions has followed last year's report by David Raup and John Sepkoski that the extinctions of marine animals over the past 230 Myr seems to have a 26 Myr periodicity. This sparked a number of hypotheses for generating periodic showers of comets from the Sun's Oort cloud — 10^{12}–10^{14} comets surrounding the Solar System and extending out to interstellar distances. Other hypotheses involved a possible association of extinctions with the Sun's harmonic motion above and below the galactic plane, which has a half-period of 33 Myr. Analysis also indicated a possible 28 Myr period in the record of large, well-dated impact craters on the Earth.

One of the first items called into question at Tucson was the reality of the 26-28 Myr periods in the fossil and crater records. Michael Rampino and Richard Stothers (Goddard Institute for Space Studies) reported a variety of periods, ranging from 12-36 Myr, from a reanalysis of the data, and similar periods in episodes of low sea levels on the Earth, geomagnetic reversals, and major tectonic episodes. They suggested that the periods are all harmonics of the Sun's 33 Myr interval between galactic-plane crossings and that a weakly-detected period of about 250 Myr is associated with the mean time between the Sun passing through galactic spiral arms.

Critics of these analyses pointed out that Rampino and Stothers had not identified any mechanisms for relating the various geophysical events to the Sun's z-motion. It has been suggested that the probability of the Sun encountering a galactic giant molecular cloud increases sharply as the Sun passes through the galactic plane, every 33 Myr. But Patrick Thaddeus and Gary Chanan (Goddard Institute for Space Studies) showed that such clouds were well dispersed above and below the galactic plane, and that encounters would occur at essentially random times (see page 73 of this issue). In addition, Piet Hut (Institute for Advanced Study, Princeton) and Scott Tremaine (MIT) presented a detailed analysis showing that galactic giant molecular clouds are not likely to be major perturbers of the Oort cloud, contrary to the idea of Biermann and Lust in 1978 and strongly argued for ever since by Victor Clube (University of Oxford) and William Napier (Edinburgh Oberservatory).

Gene Shoemaker (US Geological Survey) reported a reanalysis of the cratering and extinction records, with a best fit period of 31-32 Myr. But he pointed out that the dating for many of the extinction events is extremely poor, expecially beyond about 140 Myr ago. Shoemaker also noted that because most workers is this field now accept the idea that impacts and extinctions are related, the fossil and crater records are not independent, and might well agree in both period and phase of any pseudo-periodicity. As compelling as the evidence may seem, Shoemaker characterized it as 'shot noise' — simply a sequence of very few random events arranged with apparent periodic spacing. Support for this view came from Tremaine, who generated several hypothetical histories of random cratering and then challenged the audience to distinguish the real history from the 'best' random sample. About one-fifth of the assembled scientists chose the random sample. Tremaine then showed that statistical analysis in the random data gave a better fit to the 26-Myr period than the actual cratering history.

All this did not deter the proponents of the several mechanisms for creating a 26-Myr periodicity in showers of comets from the Oort cloud. The idea of an unseen solar companion star with a 26-Myr period has been suggested independently by Daniel Whitmire (University of Southwestern Louisiana) and Albert Jackson (Computer Sciences Corporation), by Marc Davis and Richard Muller (University of California, Berkeley), and by Piet Hut. The unseen star, presumably of low mass, would have to be in an orbit with a semi-major axis of about 87,000 astronomical units (1.4 light years) to have a 26-Myr period, but with a high eccentricity, of 0.7 or more, so that the perihelion distance is close to the inner Oort cloud where the comet density is highest. Dynamical studies by Hut, Mark

Pustuliform organs on the abdomen of the spider *Holcolaetis vidua* Lessert, magnified × 880. It may be that pheromones are secreted through the pore in each organ, and it is not inconceivable that the spherical bodies associated with, or even lodged in, the pores are 'packets' of pheromones. Mytiliform organs on the abdomens of Spartaeinae spiders may serve the same function. The two types of organ are described and compared by F.R. Wanless in the course of a revision of the spider genus *Cyrba* in the Bulletin of the British Museum (Natural History), Zoology Series 47, 445 (1984).

*"The Galaxy and the Solar System', Tucson, Arizona, 10-12 January 1985.

Bailey (University of Manchester), and Jack Hills (Los Alamos) showed that such an orbit was unstable and would be likely to escape from the Solar System in less than 1.0 Gyr. Since capture of a companion star is extremely unlikely, the orbit must have been more tightly bound in the past.

The Berkeley group believes that the last periodic extinction was about 12–14 Myr ago, so the proposed companion star, which they call Nemesis, is now near aphelion. Muller described an optical survey of 5,000 low-mass red dwarf stars, which is expected to examine all candidate stars visible from the Northern Hemisphere by the end of this year, and will be extended to the Southern Hemisphere in 1986. Nemesis, if it exists, might also be detected by the all-sky survey of the Extreme Ultraviolet Explorer Satellite, scheduled to be launched in late 1988.

Whitmire and John Matese (University of Southwestern Louisiana) suggested an alternative mechanism for creating periodic cometary showers that involves a tenth planet, some 100–150 AU from the Sun. They suggest that the orbit of the planet is eccentric and highly inclined, and that it has swept a 'clear zone' out of the inner ring of the Oort cometary cloud. As the orbit precesses, however, it will occasionally come close to the edges of the clear zone and again perturb the comets there. The comets are first thrown into Jupiter-crossing orbits, and then some fraction of them reach the Earth's orbit. Comets which do not hit the Earth are eliminated by Jupiter's perturbations in a period of about 1 Myr. Whitmire and Matese believe that the tenth planet has a mass one and a half times that of the Earth and an orbit inclination of at least 45 degrees.

I raised a number of objections to the hypotheses involving cometary showers. Current estimates of the cratering rate on the Earth and Moon from known craters on dated surfaces agree well with expectations from the observed flux of Earth-crossing comets and asteroids, whereas adding intense comet showers every 26 Myr would raise the cratering rate by a factor of 5–18, inconsistent with the observed craters. The only way out of this dilemma is to assume that the Solar System is currently in the midst of a cometary shower, and that the 'steady state' observed cometary and asteroid flux (many dynamicists hold that the Earth-crossing asteroids are extinct comets) is anomalously high. This might work with the 31–33 Myr period, which puts the last periodic extinction only 4 - 5 Myr ago, but not with the 26 Myr period, which sets the last extinction some 10 Myr farther back in time. Moreover, analyses of impact melts from terrestrial craters suggest that many were made by highly differentiated meteorites, like irons and achondrites (similar to basalts). This is inconsistent with a cometary source, since comets are believed to be the most pristine undifferentiated objects in the Solar System, a conclusion supported by analyses of interplanetary dust collected by high-flying aircraft.

The advocates of cometary showers countered that the identifications of the objects that formed the crater are still very tentative, and that the flux of comets in a shower might be up to an order of magnitude less than their original estimates, thus lowering the predicted cratering to acceptable levels. The question of whether the lower fluxes would also decrease the probability of major biological extinctions was not answered.

In the end, no hypothesis for or against periodicity emerged as clear winner, and few converts were made, but a very convincing picture emerged of the ways in which the Galaxy could affect the environment within the Solar System and on Earth. Although the conference participants did not come to any clear concensus on the extinction problem, they returned home with broadened horizons and, perhaps, with the temptation to continue to explore beyond their specialized holes. □

Biogeology

Sulphur-eating tube worms take to the Oregon breaches

from Roger N. Anderson

SCIENTISTS attending meetings of the American Geophysical Union (AGU) have grown accustomed to new reports of undersea oases of brilliant red tube worms and giant red-meated clams clustered around black smokers, which billow forth 400°C hydrothermal fluids at the axes of mid-ocean ridges. New communities from the eastern Pacific have been reported with remarkable regularity since their initial discovery in 1977. More were reported at the AGU winter meetings in San Francisco (4–9 December 1984), but there was a big surprise in store. A series of four consecutive papers[1-4] documented the presence of sulphur-eating tube worms and giant clams in a completely new environment: on the accretionary pile of sediments found above a subduction zone, where there are no hot springs.

The biological communities were found living along 'breaches' or open rifts that were discovered during dives of the submersible *Alvin* along a series of anticlinal folds of newly accreted sediments on the continental margin off Oregon, in the north-west United States. No hot-water springs were detected by the sensitive thermometers on *Alvin*, but methane-enriched waters were captured. These, along with methane-derived calcium carbonate cementation found within the surface sediments, verify that sulphur-rich waters are being expelled along the breaches. Methane and sulphur are both added to hydrothermal waters during chemical interaction with basalts of the oceanic crust.

Though not associated with hot springs, the methane-rich waters of the breaches probably have a source similar to that at ridge crests. The subduction of the Juan de Fuca plate under the coast of Oregon is the likely source of the sulphur and methane. Waters circulating in the crust eventually end up as pore fluids in sediments being accreted to the west coast of Oregon. Dewatering of these sediments is apparently a more dominant physical process than previously thought, since sufficient flow must be occuring to supply enough nutrients to support the same kind of biological community as that living near ridge-axis black smokers. Contrary to popular belief, these new observations show that hot temperatures are not required to support the organisms.

The typical sedimentary diagenesis that is observed in the area points to widespread venting all along this margin. The microcrystalline dolomite, magnesian calcite, and aragonite that surround the vents result from methane reactions. Such mineralogy is common throughout older accretionary complexes of the world. Dewatering of 20 per cent by volume of the accretionary sediments is required to support the volume of diagenetic sediments observed off Oregon. The dewatering becomes more pronounced as one proceeds away from the trench axis toward the shoreline. Tube-worm communities were sampled on vents in sediments accreted up to 1.8 million years ago.

These discoveries, and another report[5] of similar sulphur-eating organisms at the foot of the Florida escarpment, where sulphide-rich hypersaline waters are seeping out at ambient temperatures onto the sea floor 3 km below the surface, show that our tube-worm friends are more plentiful than ever anticipated. The joy of all this for geologists is that we can learn much about subsurface hydrological processes while observing some of nature's true wonders. □

Genetics

New aid to human gene mapping

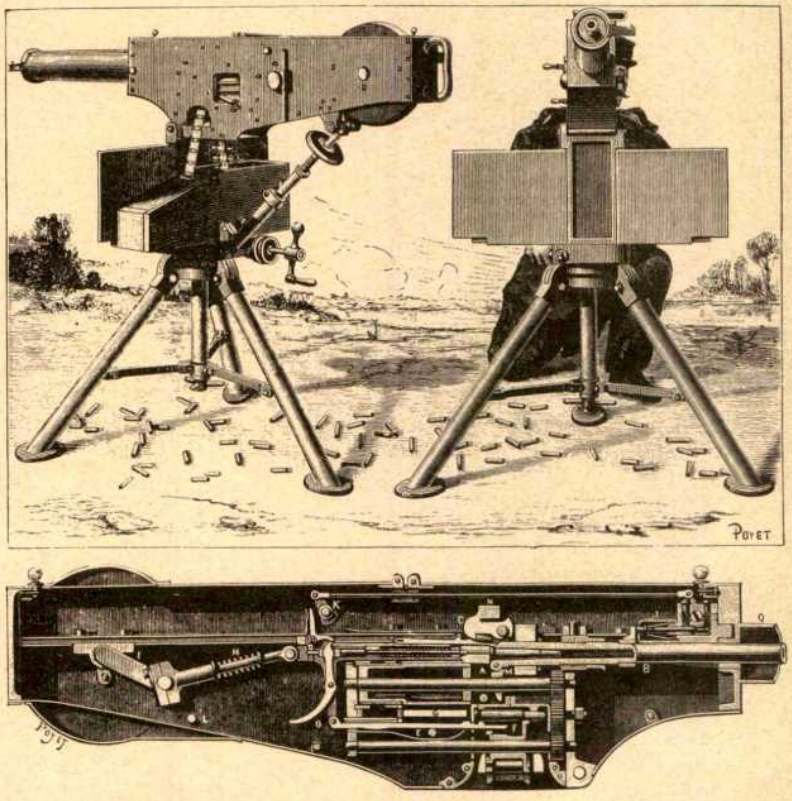
from C. Thomas Caskey

ALTHOUGH the chromosomal localizations of the genes for Duchenne muscular dystrophy[1] and Huntington's disease[2] stand as powerful examples of the use of restriction fragment length polymorphisms (RFLP) to map human genes, considerable technical difficulties still limit the application of the technique. Help is at hand with the report on page 67 of this issue[3] of a new family of DNA sequences, the characteristics of which are highly suited to RFLP linkage analysis.

Typical RFLP analysis has employed cloned functional gene sequences[4], pseudogene sequences[5] or 'anonymous' genomic probes[2], to detect what are presumed to be single base-change polymorphisms that generate or remove recognition sites for restriction endonucleases, the enzymes used to fragment DNA. Alternatively, these probes have been used to detect polymorphisms that are presumed to be due to DNA rearrangements[6]. With the exception of the last, these probes suffer from low heterozygosity because only two alleles are present in the population, one of which often occurs at a low frequency. As a result, no information can be obtained from some critical individuals in a pedigree or even entire pedigrees. Another problem is that genomic recombinants often contain highly repeated sequences that must be removed prior to analysis. Finally, closely linked polymorphic probes may not be available for a chromosomal region of particular interest.

Several of these difficulties should be obviated by the use of the DNA sequence family that is both tandemly repeated and dispersed in the human genome, and is described by Alec Jeffreys and his colleagues in this issue[3]. This family offers the opportunity to recognize multiple unlinked chromosomal loci and, with use of appropriate restriction endonucleases and specific probes, to identify variations in the number of copies of the tandem 'minisatellite' at each locus. The variation in copy number is seen as an RFLP by standard Southern blotting techniques and some loci are shown to be highly polymorphic for copy number of members of this repeat family (multiple alleles).

The minisatellite was first detected during characterization of the human myoglobin gene by Jeffreys and colleagues[7] as an intron sequence that contains four tandem repeats of a 33 base-pair subunit and bears similarities to highly polymorphic sequences that are found near several other genes[8,9]. A probe constructed as a concatamer of this repeat has now been used to identify numerous genomic lambda clones which contain sequences homologous to the repeat. Eight of the clones were selected and further characterized. They differ in their base sequence, number of repeat units and, apparently, in their localization within the human genome (that is, they are not closely linked). All the repeat units, however, share a similar 'core' of 10-15 base pairs. Three of the eight repeats studied are highly polymorphic in copy number when hybridized under high stringency to DNA from various individuals. Pedigree analysis by Southern blotting shows that bands representing different copy numbers of repeats are inherited in a Mendelian fashion. Furthermore, the heterozygosity of these highly polymorphic repeats appears to be close to 100%. Thus, it is highly likely that these probes can yield information for analysing the pedigrees of families affected by a closely linked disease gene.



In order for these probes to be useful the chromosomal localization of the minisatellites will need to be determined. But it is clear that they provide an interesting and potentially significant improvement in the use of RFLP's for prenatal diagnosis, linkage studies, and gene mapping. Other polymorphic satellite DNA probes have been reported[10,11], but they do not seem to have the same widespread potential in human gene mapping. Minisatellite sequence families offer the advantages of multiple chromosomal localization and greater heterozygosity at a given locus. Jeffreys *et al.* have described one, but their report holds out hope that other minisatellite families, which would make useful polymorphic probes available throughout the genome, await discovery.

Because the 'core' sequence of the repeated units resembles the generalized recombination signal of *Escherich coli*, a further use of these minisatellite sequences may be in the study of unequal crossing-over, the presumed mechanism for generating heterogeneity of copy number within a tandem repeat. □

100 Years Ago **The Maxim Gun** **From *Nature* 31 414, 5 March 1885.**

MR. HIRAM STEVENS MAXIM, the well-known American engineer, has lately brought out a new form of a machine-gun, which is attracting a great deal of attention in military and naval circles. This gun is a completely new departure. It takes the cartridges out of the box in which they were originally packed, puts them into the barrel, fires them, and expels the empty cartridges, using, for this purpose, energy derived from the recoil of the barrel.

Lysosomes and prohormone activation

SIR – The interesting *News and Views* article by Pfeffer and Ullrich[1] refers to the unexpected relationship between the structure of the low-density lipoprotein and epidermal growth factor (EGF) receptors and that of the biosynthetic precursor for EGF itself. Pfeffer and Ullrich believe that a new clue to the puzzle is provided by the letter in the same issue of *Nature*[2] reporting the detection of unprocessed EGF precursor, but not EGF itself, in mouse kidney. The authors of this letter envisaged the possibility that the EGF precursor is a membrane protein and that it might function as a receptor in the cells of the distal tubules to regulate membrane transport events. This exciting new information, together with other clues to the puzzle, invites the re-evaluation of a suggestion I made a few years ago, prompted at that time by the related problem of the existence of prohormones[3,4].

In brief, it was proposed that polypeptide hormones have evolved from the constituent proteins of the secondary lysosome of simple unicellular organisms. A key element of this hypothesis was that the membrane of the secondary lysosome must contain transport processes. Hence the agents and products of lysosomal digestion would have direct access to, and the possibility of regulating, nutrient transport processes. Regulation of nutrition is a major feature of the action of many polypeptide hormones and growth factors. (As a result of this concept a glucose transport system was searched for and found in lysosomes[5].) It was also proposed that the proteins which could act as polypeptide hormone precursors included membrane transport proteins and lysosomal digestive enzymes. "If some of the effectors arise by partial degradation of membrane proteins, then a structural relationship could exist between some effectors and receptors"[3]. A structural relationship between cobalamin binding proteins and their receptors has been recognized[6].

Further informative structural relationships between a membrane protein, transport, nutrition and growth promoting activity, have emerged around transferrin and its receptor. The transferrin receptor shows weak homologies with the EGF precursor and chicken transferrin precursor[7]. Transferrin itself appears to be structurally and functionally related to an iron-binding cell surface glycoprotein which is present in most human melanomas, fetal intestine and, in trace amounts, normal adult tissues. This protein may translocate iron[8]. Transferrin has growth factor activity and stimulates the growth of some cells independently of its iron binding[9]. Finally the nucleotide sequence of a transforming gene suggests that it encodes a protein partially homologous to the amino terminus of transferrin, suggesting possible functional similarities[10]. It is possible that this smaller peptide is growth-stimulating with a role similar to that proposed for platelet-derived growth factor in malignant transformation[10,11].

Pfeffer and Ullrich also mention that the precursor for a polypeptide homologous to EGF, transforming growth factor (TGF)-alpha, has a sequence suggestive of its being a membrane protein. It should perhaps be added in the present context that TGF-α and EGF show homology to the serine proteases urokinase and tissue-type plasminogen activator[12], and that EGF appears to be related to pancreatic secretory trypsin inhibitor[13]. The EGF precursor also appears to be structurally related to the serine protease factor X and more generally to the family of blood coagulation zymogens which includes prothrombin[14]. Thrombin itself has mitogenic activity and triggers a number of platelet reactions including secretion. These effects are not due to its protease activity but are considered to be hormone-like[15]. Other thrombin sequence homologies which have been described include those with angiotensin and the β-chain of luteinizing hormone[16]. It has recently been recognized that human γ-trace, a polypeptide having some homology with glucagon and corticotropin[17], is an extremely potent cysteine-proteinase inhibitor[18]. The K_i for γ-trace inhibition of cathepsin L is less than 0.005 nM[18]. Thus a picture of close interrelations between some polypeptide hormones, proteases and their inhibitors emerges.

The sequence information which has emerged to date is consistent with the hypothesis that the lysosomes are involved in the activation of prohormones, suggesting that it may provide a useful framework for making and interpreting structural comparisons in this area.

Agreement between optical and radiocarbon dating

SIR — D.J. Huntley *et al.*[1] recently described a new method for dating sediments. They compared their optically dated age of 62±8 kyr for a sample with a radiocarbon dated age of 58.8±0.3 kyr. In fact, the agreement is even better than Huntley *et al.* indicated, since the radiocarbon age used for comparison is based upon the wrong half-life for ^{14}C.

For well over twenty years, it has been internationally agreed to continue to use the Libby half-life value of 5,568 years for ^{14}C (ref. 2), although the best value was acknowledged to be a factor of 1.03 larger[3]. The procedure was justified by the desire to avoid the confusion which would arise should the many thousands of published dates require revision[4]. It should be noted that all radiocarbon dates are consistent among themselves but 3% lower than the true age.

As a result, the true (radiocarbon) age for Huntley *et al.*'s specimen would become 60.6±0.3 kyr, which is in excellent agreement with their 62 kyr value.

Right-handed flagella in tumbling *Caulobacter*

SIR — In a pair of fascinating *News and Views* articles, Michael Spencer has recently discussed the remarkable case of bacteria that have right-handed helical flagella but are still able to reverse direction without tumbling, by simply changing the sense of rotation from clockwise to counterclockwise[1]. There seems some uncertainty, however, about when such bacteria were discovered. Spencer presents data from the work of Alam and Oesterhelt on *Halobacterium* species[2]. But the first bacteria to be discovered with such properties were in fact *Caulobacter crescentus* — they were studied by us in the University of Tokyo and the work was reported in an earlier edition of the same journal[3].

THE WIDE, WIDE WORLD OF SCIENCE

PRINCIPLES OF MEDICAL THERAPY IN PREGNANCY

edited by **Norbert Gleicher**

This new handbook covers the management of all types of medical disorders in pregnancy. Each chapter is written by an expert on the subject discussed. An essential reference for obstetricians, internists, and any clinician who deals with pregnant patients.

0-306-41845-2/1,233 pp. + index/ill./1985
$125.00 ($150.00 outside US & Canada)

THE HERPESVIRUSES

The Herpesviruses is a subseries within The Viruses, a series edited by Heinz Fraenkel-Conrat and Robert R. Wagner.

Volume 3
edited by **Bernard Roizman**

Focuses on pseudorabies, herpes simplex viruses 1 and 2, and human cytomegalovirus.

0-306-41778-2/432 pp./ill./1985
$55.00 ($66.00 outside US & Canada)

Volume 4 • Immunobiology and Prophylaxis of Human Herpesvirus Infections
edited by **Bernard Roizman** and **Carlos Lopez**

Molecular Structure: Macromolecules in Three Dimensions

R.J. Fletterick, Trina Schroer and R.J. Matela
1985. 212 pages, 153 illustrations. Paper, £19.80

The Blackwell Molecular Models Kit
Contains 66 red and 70 green parts, 118 connectors and 510cm or rod, packaged.
£29.80

Molecular Structure, along with the *Blackwell Molecular Models Kit*, presents fundamental chemical and physical principles that determine the conformations and three-dimensional structures of proteins and nucleic acids. The book is intended to develop understanding of the atomic nature of the structure and function of molecules through the study of models. The text is written at an introductory level, and is designed for undergraduate students and sixth formers of biology, and those in specialised fields such as, molecular biology, genetics and cell biology. It is an important addition to the classroom or laboratory.

Also . . . **a set of fifty 35mm slides** may be purchased to accompany *Molecular Structure* and its models. A booklet listing each slide provides background information for the viewer or instructor.
£100.00

UNDERSTANDING DNA AND GENE CLONING:

A Guide for the Curious

by **K. Drlica,** *University of Rochester*

Written for non-scientists (with no background in chemistry), this compact text organizes relevant information into a manageable, understandable format. Using gene cloning as a framework to describe the molecular biology of information storage and utilization of cells, the author discusses how recombinant DNA technologies are providing new insights into the life process. Also covered are recent developments in the field.

Contents: Preview; Bacterial Growth; Gene Expression; Reproducing DNA; Gene Splitting; Plasmids and Phages; Cloning a Gene; Using Cloned Genes; Recent Surprises; Additional Reading; Appendix I: Attenuation; Appendix II: Transmissible Plasmids; Appendix III: Cloning with Plasmids.

0471 87942 8 220pp October'84 £12.50

AN INTRODUCTION TO RECOMBINANT DNA

by **Alan E.H. Emery,** *The Medical School, Edinburgh*

Recombinant DNA technology, or genetic engineering, has an increasingly important role in medicine, and although there are many textbooks of molecular biology, this book provides an introduction to this complex subject particularly for those with a medical orientation. The book is profusely illustrated throughout with clear line diagrams, and will be invaluable in confirming the significance of the subject in modern medicine.

Contents: Prologue; The Development of Recombinant DNA Technology; Structure and Function of DNA; The Technology; Gene Mapping, Structure and Function; Molecular Pathology of Unifactorial Disorders; Molecular Pathology of Some Common Diseases; Prevention of Genetic Disease; Treatment; Some Broader Applications; Problems and Future of Recombinant DNA; Glossary; Index.

0471 90363 9 234pp October'84 (paper) £6.75

ECOLOGY OF NATURAL RESOURCES

by **F. Ramade,** *Laboratoire de Zoologie et d Ecologie, Universite de Paris-Sud (Orsay)*

Discusses the application of ecological principles, tools and data to the conservation and management of the biosphere. It provides an analysis of the ecological implications of man's use of his environment and an assessment of the strategies needed to conserve and optimise natural resources in the future.

0471 90104 0 246pp December'84 (cloth) £34.00

STATISTICAL TECHNIQUES IN GEOGRAPHICAL ANALYSIS

by **G. Shaw,** *Department of Geography, University of Exeter,* and **D. Wheeler,** *Department of Geography, Sunderland Polytechnic*

A guide to elementary and multivariate statistics that aims to cover the undergraduate geographers needs in statistical methods from their first to final year. The authors have kept in mind the needs of the non-science trained geographers by avoiding difficult mathematics and have made use of worked examples and exercises to reinforce points made in the text.

GENES

2nd Edition

by **B. Lewin,** *Massachusetts Institute of Technology*

A second edition of a widely recognised and authoritative text, written by an authority in the field. Emphasizing modern topics, this updated edition reflects progress in DNA technology and focuses more on direct analysis of the genome. Preliminary chapters now examine the biochemical basis for heredity as seen through the structure of DNA, making it accessible for the student with only a casual knowledge of biochemistry. Features include extensive new figures, drawings, and illustrations.

Contents: DNA as a Store of Information, Turning Genes into Proteins, Producing the Template; Controlling Gene Expression/Prokaryotic; Constitution of the Eukaryotic Genome; Clusters of Related Sequences; Reaching Maturity: RNA Processing; The Packaging of DNA; Prepetuation of DNA; The Dynamic Genome: DNA in Flux; Glossary; Index.

0471 80789 3 732pp February'85 (cl) £47.10
0471 82068 7 732pp February'85 (WIE) £16.75

UNDERSTANDING MEDICAL IMMUNOLOGY

by **E.M. Kirkwood** and **C.J. Lewis,** *Department of Bacteriology and Immunology, Western Infirmary, Glasgow*

A book on medical immunology for those who are not immunologists as such, but whose occupation requires an understanding of certain immunological problems, either at a clinical or laboratory level. The book has been carefully written and designed to ensure that the reader is not bombarded with terminology, but rather to give a complete overview of immunological concepts in relation to medicine.
The information is presented in atlas form as a series of logically developed topics and themes, each dealt with as an illustration with annotated text. A single page is devoted to each topic to ensure easy reference.

0471 10529 5 128pp February'84 (paper) £7.95

A PRACTICAL GUIDE FOR THE OBSTETRIC TEAM

edited by **M.D. Read,** *North West Health Authority,* **D. Wellby,** *Queen Elizabeth Hospital, Adelaide, Australia,* in Association with **C. Pawley,** *Queen Elizabeth Hospital, Adelaide, Australia* and **D. Brears,** *South Manchester Health Authority*

Describes the practical aspects of management of pregnancy and childbirth. It is not intended to be a comprehensive textbook of obstetrics or midwifery but rather a concise and readable account of the normal course of pregnancy, the problems which might arise, and their recommended treatment. It does not distinguish between the traditionally accepted roles of obstetrician and midwife but rather discusses the important aspects of the subject common to both in the management of patients.

0471 90584 4 296pp January'85 (paper) £9.75

CELL BIOLOGY:

Structure, Biochemistry, and Function, 2nd Edition

by **P. Sheeler** and **D.E. Bianchi,** *both of California State University, Northridge*

An in-depth investigation of the structure, biochemistry, and function of cells, their organelles and other constituents. This updated edition gives greater emphasis to cell structure and genetics and discusses recent developments in the field.

0471 09308 4 688pp April'83 (cloth) £42.25

A tax not for imposition

On Budget day, 19 March, the British government may announce it is to impose value added tax on publications. The proposal might be economically rational but should be resisted.

FOR more than the past six months, British publishers and the British consumers of their products have been buzzing with anxiety at the proposal that there should be a tax on publications. The issue is simple. Should the government, in pursuit of its laudable ambition to shift the burden of taxation from income taxes to what is called indirect taxation (which applies to what people purchase), impose a kind of generalized expenditure tax on publications?

Such a move would be widely and fiercely scorned. On 19 March, when the budget for the coming financial year is known, it should be clear whether the British government is ready to go down yet another unpopular road.

That is why it is important not to exaggerate the case against a tax on publications. Value added tax (known as VAT) is in principle an economically rational and an equitable form of tax. The idea is that, in the manufacture of goods or the provision of services, each commercial entity will pay VAT on all purchases used in its business, collect VAT from all its customers, and hand over the difference between the output and the input tax to the government. At the end of each commercial chain stands the ultimate consumer, for whom VAT is a tax on expenditure. But because of the way in which the tax is structured, the burden is collected from all who have contributed to the production of something saleable in proportion to the value they have added to the final product. By now, VAT is a familiar part of the European scene, and even the basis on which the annual budget of the European Communities is calculated. As taxes go, VAT is a splendid principle. It would no doubt be more popular if it were more easily understood, and if its administration were not appallingly cumbersome.

In parochial Britain, for the past six months the popular slogan thrown at the proposal to levy VAT on publications is that such a move would be a "tax on knowledge", but that is not easily sustained. The most obvious difficulty is that there are many types of publication which can hardly be called educational or scholarly. Further, there are already many intellectual commodities in Britain and elsewhere in Western Europe which are taxed in exactly the same way. Those who buy tickets at theatres, opera houses and concert halls are already paying VAT. Who is to say that these institutions contribute nothing to the pool of knowledge of cultivated societies? That a performance of Beethoven's *Ninth Symphony* should be taxed when *Pride and Prejudice* is exempt?

As things are, in Western Europe, something like 40 per cent of purchases of goods and services is subject to VAT, in most countries at a single percentage rate (which is, at present, 15 per cent in Britain). VAT is not levied on necessities of life such as food (except in restaurants) and rent, but unambiguously attaches to most manufactured goods, television sets for example. Publications are not taxed in this way, while commercial publishers are "zero-rated" in the sense that they neither pay tax on their inputs nor charge it on their products. Elsewhere in the European Community, in West Germany and, more recently, in Ireland, VAT applies.

So on what grounds should publications continue to be lumped in with food (but not drink) as necessities of life? The easy argument, that a tax that impedes the free flow of information within a democratic society is a threat to its well-being, is too riddled with inconsistency to be easily defended. One difficulty is that it has been readily, perhaps too readily, accepted that the commercial organizations willing to provide cable television services in Britain (and still waiting to see whether there is substance in the government's promise to "cable Britain") will be taxed by VAT. Another is that telephone calls, which are as powerful a means of conveying information as many publications, are also taxed, perhaps iniquitously. Compliantly to have accepted these taxes but to resist that now proposed for printed publications is inconsistent and, therefore, unwise.

The true case against the British government's flirtation with the proposal to levy VAT on printed publications is different and more pragmatic. There is a host of ways in which VAT would have disastrous consequences, one of which should be clear from the pages which follow where the virtues of a year's crop of textbooks are reviewed. A glance at the prices shown at the head of each review will be to most people a prompt for the question "how can students afford them?". So how will they get by if the cost is increased by another 15 per cent? Further depriving them of essential tools would throw doubt on the quality of education as such.

The case of learned journals is more complicated, and more shot through with potential inequity. The National Book Committee in Britain, an admitted lobbyist against the VAT proposal, has nevertheless produced some telling figures as part of its case. Surprisingly, it calculates that learned journals produced in Britain account for some 28 per cent of the titles in international currency, but that the sales of these journals within the United Kingdom account for only 21 per cent of the total (reckoned as £187 million a year).

Even allowing for what may be very large errors in these estimates (based on replies to questionnaires), the figures suggest that the plan to levy VAT on publications would be a way of further and arbitrarily increasing costs in a modestly substantial export business where price-resistance is already strong. (Libraries everywhere are short of funds.)

The way in which the effects of VAT would discriminate between different kinds of customers and publishers would however be absurd. Commercial publishers (such as those of *Nature*) would at least be able to offset their input tax (paid out) against their output tax (collected from customers), but learned societies would have no such relief. Similarly, universities (already skimping unwisely on library acquisitions) would have no way of recovering the tax paid to publishers, but the libraries of commercial research laboratories, for example, would be able to deduct VAT paid on journals from that collected from the ultimate customers of their operations.

And while, in theory, VAT should be levied on imported publications, there is plainly no way in which this could be done on subscriptions serviced from abroad. (As Ireland has discovered to the cost of its own newspapers; VAT has been a boon to those who ship in British newspapers.) Yet a little discouragement of this kind could provoke a rapid emigration of many important journals that could be based anywhere in the world, and which are in Britain by historical accident. Is that what the British government wants to see occur?

But why not anticipate these untoward consequences of the imposition of VAT, and make arrangements that vulnerable groups of users, or publications, should be exempt? That seductive argument is the most dangerous of all, for it is a way of inviting the British government to discriminate between different kinds of publications. It amounts to censorship of a kind. Nobody, perhaps not even the government, wants that.

This is why a sensible decision about VAT on publications is bound to be a difficult decision. The government may like to think that the benefits of less direct taxation will put so much more money into people's pockets that the obvious economic consequences of the tax will be outweighed. In a more prosperous Britain, there might be something in that calculation. But as things are, VAT would further undermine the British academic enterprise, would begin a flight from Britain of many important institutions and would spread yet more intellectual impoverishment in a society that has long since lost its reputation for being widely read. Living with a little inconsistency is the better course. □

Matters of gravity

John D. Barrow

General Relativity and Relativistic Astrophysics. By Norbert Straumann.
Springer-Verlag: 1984. Pp.459. DM 112, $42.
A First Course in General Relativity. By Bernard Schutz.
Cambridge University Press: 1985. Pp.376. Hbk £30, $54.50; pbk £9.95, $19.95.
General Relativity. By Robert M. Wald.
University of Chicago Press: 1984. Pp.491. Pbk $34, £31.50.

EVER since the classic texts by Weyl and Eddington, written soon after the inception of general relativity, there has been a steady stream of high quality expositions of Einstein's route to his new theory of gravitation. Most have stayed close to the path first beaten by Einstein himself, which he described in the many editions of his own *The Meaning of Relativity*. Subsequent descriptions of general relativity have tended to focus upon polishing-up the standard route towards the field equations taken by Einstein, expounding the equivalence principle, covariance, tensor analysis, curvature and the field equations, before moving on to Schwarzschild's solution and the classical experimental tests of the theory. The situation is slightly reminiscent of the multitude of users' guides for the better known personal computers, each a minor revision of the manufacturer's manual.

Yet for all this duplication the didactic profile of general relativity has been dominated by a small number of influential books with very definite, but very different, points of view as to which aesthetic criteria should be emphasized in its formulation. While some authors regard the geometrical basis of the theory as the essential element in its formulation, others see this feature as an occlusion that inhibits its connection with the rest of physics. While one author may take a version of the principle of general covariance as its paramount guiding light, another may ignore it entirely or stress that it is empty of all physical content. This essential ambiguity in the initial motivation for entering into the mathematics along the lines followed by Einstein was the main reason for the proliferation of textbooks until the early 1970s. Since then, the motivation has changed: the development of more elegant and powerful coordinate-free formalisms has dominated the modern research literature in relativity and has begun to be promoted in new teaching texts. Further, there have been exciting new applications of general relativity to astrophysics and in the development of a unified approach to the natural forces. General relativity has finally ceased to be embarrassingly disjoint from the rest of physics, a haven only for group theorists and differential geometers.

These three books reflect the need for systematic expository texts that treat new theoretical and observational developments in modern mathematical language. Straumann's volume is the most formal in style, and has arisen from series of graduate lectures. It is divided into three parts which hang rather uneasily together.

The first part is a rigorous and detailed description of modern differential geometry and could be used as a course on this topic. Very clearly written, it takes the approach of the mathematician rather than that of the physicist; beginning with differentiable manifolds, it leads on to differential forms and the use of coordinate-free techniques for describing curvature. The second part then develops general relativity and contains detailed chapters on the behaviour of weak gravitational fields and the post-Newtonian approximation. Here, I found the exposition clear when the emphasis was on the mathematical formalism but rather weak on the link between physical principles and the mathematics. The last third of the book is much more physical and deals with relativistic astrophysics: neutron stars, the Kerr black hole and the laws of black hole mechanics, binary X-ray sources and, in the final chapter, the problems of accretion disks around black holes. All these astrophysical chapters are written at a high level but fall short of the standards set by Shapiro and Teukolsky's outstanding graduate textbook, *Black Holes, White Dwarfs, and Neutron Stars* (Wiley, 1983). There are a small number of exercises scattered throughout the text but I did feel this to be an intended textbook that was written and printed in the somewhat forbidding style of a monograph.

Schutz is a well-known relativist who specializes in the study of gravitational radiation and equations of motion in general relativity. In this book he has put together a very carefully constructed course on general relativity which, unlike Straumann's, can be used by both undergraduates and graduates. Its great strength is the author's evident experience in teaching its content. The book is a goldmine of cleverly constructed problems and exercises (and solutions!) — there must be nearly 500 in total and a lot of careful planning has gone into their devising. This feature alone is sufficient to make this text far more appealing than Straumann's.

Schutz devotes the first 50 pages to recasting special relativity and vector analysis in modern formalism, before launching into tensors. Yet one wonders whether the level of detail here might not inhibit all but those able to chart a short-cut through this material from employing it as a core text, simply because of the limited length of undergraduate courses at British universities. But those seeking a basis for an advanced graduate course on the behaviour of gravitational radiation and black holes will find the author's evident mastery of the subject, and his ability to avoid mathematical formalism for its own sake, a strong attraction. The final chapter gives a brief but useful introduction to the homogeneous and isotropic cosmological models. Strongly recommended.

Wald's book is for a graduate course but, unlike its two competitors here, will be also extensively used by research workers because it is the first pedagogic treatment of so many advanced topics and techniques that form the research frontier of the subject. The author employs the so-called

Bildarchiv Preussischer Kulturbesitz

abstract index notation rather than traditional tensor notation. The formal treatment of manifolds, differential forms, continuous transformation groups, conformal transformations and the Hamiltonian formulation are all contained in extensive appendices that are designed to be integral parts of the text, displaced from the main body only on the grounds of continuity.

The first portion of the book covers the traditional ground from special relativity to Einstein's equations in a mathematical manner that I found was slightly lacking in its discussion of the physical motivation and content of the formalism; perhaps it is assumed that the reader has already followed a traditional introductory course? However, the outstanding part of this book is the treatment of a wide range of advanced topics in the second half of the text. Modern techniques for generating and classifying exact solutions to Einstein's equations, the causal structure of space-time and the use of techniques from differential topology to prove singularity theorems are all developed in detail. Each chapter is followed by a number of problems, although solutions are not supplied. The final series of chapters provides modern discussions of the initial value problem and Penrose's conformal treatment of infinity. These later chapters also focus upon topics close to the author's own research interests and there is a particularly nice introduction to developments in quantum gravity and the study of quantum fields in a classical curved space-time as well as detailed discussion of black hole mechanics and thermodynamics.

This is a much-needed book that will greatly stimulate the teaching of advanced graduate courses in modern gravitation physics. It will also provide an invaluable directory of modern techniques and results for gravitation theorists. □

John D. Barrow is a Lecturer in Astronomy at the University of Sussex.

Physical reasoning

Colin Upstill

Theoretical Concepts in Physics.
By M.S. Longair.
Cambridge University Press: 1984. Pp.366. Hbk £25, $49.50; pbk £8.95, $14.95.

IT IS the exception rather than the rule for brilliant scientists to be the best teachers: Planck studied under Helmholtz and Kirchoff, but confessed that "the lectures of these men netted me no perceptible gain". Most of us have at some time had the same experience, going full of expectation to a lecture by some professor of renown, only to find the lecture-room clock of more interest than his impenetrable phrases and even more impenetrable algebra.

Sadly, good textbooks are a rarity too. The texts whose content best matches our syllabuses are all too often hastily compiled pot-boilers, spin-offs from others' fumbling attempts at courses with similar titles to our own. It is of the greatest value in university teaching to possess a full and deep understanding of one's subject matter, yet to be aware of what it is like to be a student who does not. Professor Longair has this rare gift, and he has used it to good effect in writing this excellent book, subtitled *An Alternative View of Theoretical Reasoning in Physics for Final Year Undergraduates*. The subtitle hardly does the book justice; it is a complement rather than an alternative to most standard courses and standard texts — providing the cement of understanding to put between the blocks of lectures which go to build a physics course.

For most of the topics covered, Longair has leant heavily on the best treatments available elsewhere, and has often gone back to the original literature — for men such as Einstein, Maxwell and Rayleigh expressed lucidly ideas which subsequent generations of authors have muddled and obscured. It is no surprise to find that the book owes a great debt to Feynman's three-volume *Lectures on Physics* (Addison-Wesley, 1963–1965). But let me make it quite clear that Longair's book is much more than a collation of familiar material from diverse sources; throughout, it is stamped indelibly with the author's own deep insights and, equally important, his enthusiasm for his subject. This enthusiasm comes over vividly, and has resulted in a learned book with the rare property that it is compelling: like a well-crafted novel, it is hard to put down; at the end of each chapter, one turns the page eager to see what happens next. In my view, Longair has provided for final-year physics undergraduates the sort of essential background Feynman gives them in their first and second years. No facet of the reality of the practice of physics is omitted, from the importance of experimental observations for theory (via Kepler's use of Tycho Brahe's observations and especially his error analysis, which was so crucial to the discovery that the orbits of the planets must be elliptical rather than circular), through the use of models (such as Maxwell's mechanistic models for electromagnetic phenomena), to the use of computers (to simulate the synthesis of light elements in the hot big bang).

In his epilogue, Longair admits that in preparing the book he learned a great deal which he wished he had known years ago. I feel the same after reading it. □

Colin Upstill is a B.P. Venture Research Fellow at the H.H. Wills Physics Laboratory, University of Bristol.

Round the mechanics course

J.W. Humberston

Classical Mechanics*.
By B.P. Cowan.
Routledge & Kegan Paul: 1984. Pp.111. Pbk £3.95, $9.95.

CLASSICAL mechanics continues to be regarded as an essential component of a modern degree course in physics, and this book attempts to cover all the material required by a student taking a first course in the subject. It is a rather bold claim to make of a book containing only 111 pages, but the choice of topics is generally satisfactory. There are chapters on Newton's laws, energy and momentum, dynamics of a single particle, many-particle systems and rigid bodies, and non-inertial frames. The final chapter gives a very clear introduction to Lagrangian and Hamiltonian mechanics, ending with a brief section on Poisson brackets and their relationship to commutators in quantum mechanics. Worked examples are distributed throughout the book and a short set of problems (with solutions) is also included.

Because the book is so small, there are, inevitably, omissions. For me, the most serious of these relates to moments of inertia. After a brief account of the inertia tensor there is merely the statement that the diagonal elements are the moments of inertia. No mention is made of the motion of a rigid body about a fixed axis (unless it be a principal axis) nor of the theorems of parallel and perpendicular axes. There is not even a worked example of the calculation of a moment of inertia.

Also, in the discussion of motion under an inverse square law of force, insufficient detail is given of the properties of conic sections. It is assumed, I would have thought unreasonably, that the reader is already familiar with them. A bibliography of more extensive works in mechanics would have been some compensation for these and other omissions but, unfortunately, one is not provided.

The book is written in a clear and concise style and, despite its shortcomings, should generally be well received by its intended readership. □

J.W. Humberston is a Lecturer in the Department of Physics and Astronomy at University College London.

*A volume in Routledge & Kegan Paul's *Student Physics* series. Other titles to appear during 1984 were *Quantum Mechanics* (by Paul Davies), *Relativity Physics* (Roy Turner) and *Electricity and Magnetism* (Roland Dobbs). All are short paperbacks costing £3.95, $9.95. Forthcoming later this year are *Electromagnetic Waves* (Roland Dobbs) and *Liquids and Solids* (Michael Sprackling).

Good companions

Robert Connon Smith

Astrophysics. Vol. I Stars. Vol. II Interstellar Matter and Galaxies.
By Richard Bowers and Terry Deeming.
Jones and Bartlett/Wadsworth: 1984. Vol. I pp.344, Vol. II pp.244. $37.50, £17.95 each volume.

THE main teaching load for astronomers in the United States is the large first-year class of liberal arts students and so there are many textbooks jostling for a place in that market. In British universities it is more common to teach astronomy only to science specialists, usually in the context of physics courses. Good books at that level are rarer and so it is a pleasure to find a new two-volume work that caters for the advanced undergraduate or beginning graduate student.

In 588 pages the books attempt to cover the whole of modern astrophysics, excluding the Solar System. The task is made easier by the assumption that the reader already has an elementary knowledge of astronomy, presumably from one of the myriad first-year descriptive texts, but nonetheless the authors succeed remarkably well in providing a comprehensive coverage at a useful depth. They are not content with order-of-magnitude arguments — though these are well-used where appropriate — but give proper mathematical derivations while managing to avoid the generality of treatment that only serves to confuse the new student.

This is not a research monograph and so is not completely up to date. For example, the discussion of supernova models mentions radioactive decay as an explanation for the exponential tail in the light curve of a Type I supernova but attributes the decay to Cf^{254} rather than to the more likely Co^{56}. In the more general discussion of stellar evolution, there is little emphasis on mass loss, except through mass transfer in binary systems. However, the volume on stars is more complete than its companion, in which there is little hint of the modern picture of the violent interstellar medium, and almost no discussion of interstellar molecules. The exciting subject of active galactic nuclei and quasars gets essentially no mention at all. These and other omissions make the books more suitable for undergraduates than for graduates, though the latter will learn useful things about longer-established branches of astrophysics. Even in these branches there are some surprising gaps, however, such as the absence of any detailed account of how the rotation curve near the Sun is found. As a whole the second volume is not as good as the first, being less complete and less balanced. It also stops rather abruptly, with no attempt to draw ideas together.

Still, I liked these books. They are readable and well-illustrated, full of short but useful problems and include some helpful suggestions for further reading. Without producing something twice the length it is doubtful if a much better job could have been done, and I shall certainly be including them on reading lists for my own students. □

Robert Connon Smith is a Lecturer in Astronomy at the University of Sussex.

Out of this world

David W. Hughes

The Universe of Galaxies: Readings from Scientific American.
Compiled by Paul W. Hodge.
W.H. Freeman: 1984. Pp.113. Hbk $20.95, £23.95; pbk $10.95, £12.50.
A Workbook for Astronomy.
By Jerry Waxman.
Cambridge University Press: 1985. Pp.356. Comb bound £15, $19.95.
Planets and Their Atmospheres: Origin and Evolution.
By John S. Lewis and Ronald G. Prinn.
Academic: 1984. Pp.470. Hbk $59, £49.50; pbk $29.50, £25.
The Solar System.
By Barrie William Jones.
Pergamon: 1984. Pp.336. Hbk £24.25, $40; pbk £11.75, $19.50.

ASTRONOMERS at the chalk face of tertiary education have a lot to be grateful for, not the least being the hard work of authors and publishers. Astronomy has popular appeal, and so attracts the attention of glossy scientific journalism; it has a strong practical edge and many new ideas for laboratory experiments have been laboriously written up into book form; and it is fast moving, an attribute that results in a stream of updated textbooks.

At the forefront of the popularization of astronomy are the monthly astronomical reviews that appear in *Scientific American*, noteworthy for their clarity of exposition — both in text and in figures — and the erudition of their authors. Periodically the publishers gather together articles on a specific topic and issue them in a large-format paperback. *The Universe of Galaxies* is one such collection. It starts with a paper by Bok on our own galaxy and moves out, encompassing the Andromeda galaxy, dark matter in spiral galaxies, the evolution of disk galaxies, tides between galaxies, active galaxies, cosmic jets, superclusters, voids and quasars. The important word in the title of the book is *Readings*. It has never been easy getting students to read and *Scientific American* must be praised for coaxing many and enlightening most.

Practical work is crucial to astronomy — observations must be made, spectra analysed, graphs plotted, errors calculated and results mused over. But how do we introduce this aspect of the subject to the throngs in arts faculties that take a science course in astronomy at American universities. These students dive into astronomical texts by the likes of Abell, Pasachoff and Hartmann and read, somewhat grudgingly, enough of them to pass the course. They must be encouraged to wander into the laboratory planetarium and observatory. Waxman's book is a valuable start, providing a complete set of practical activities to supplement the factual meal to be gleaned from the textbooks. Suggested activities are divided into three time categories, short ones which can supplement a lecture, longer ones suitable for a three-hour laboratory class and others concentrating on outside observations which can be carried out individually and can extend over many weeks.

A Workbook for Astronomy contains a multitude of bright ideas and, what is more important, the wherewithal for carrying out the experiments — finder charts for binaries, comparison spectra, lunar charts, reproductions of crater fields, star charts and photographs of clusters of galaxies. Students are introduced to a wealth of topics including stellar evolution, distance measuring, planetary orbits, the curvature of space, the age of clusters and classification of galaxies. They learn by doing. I found the book a source of many good ideas but for British science teaching the standard is rather elementary. Also,

while I can see very little advantage to the student in having the book held together by a plastic ringbinder, the advantage to the publisher is obviously enormous. After one year of use the book falls to pieces and the owner cannot recoup some of his outlay by selling it to those who follow. The quest to reduce the second-hand value is also helped by including "data sheets" and graph paper (with marked axes!) in the text. This surely spoonfeeds students too much, for one of the objectives of laboratory exercises is to introduce them to the craft of tabulating results and planning graphs.

The other two books reviewed here both deal with our Solar System. Lewis and Prinn have provided, in *Planets and Their Atmospheres*, the ideal starter pack. It is not for the faint hearted, however, being aimed accurately at the final-year student, postgraduate and research worker. To this end the authors have assembled an impressive 70 pages of references and a detailed, itemized index which has at most five page numbers for each topic. The book is also timely. Spacecraft have provided an enormous bank of data about the present atmospheres of the terrestrial planets Venus, Earth and Mars. Observations of Jupiter, Saturn, Uranus, Neptune, Titan and Io have also helped us formulate models for the structure, composition and chemistry of their gaseous mantles. Detailed comparative studies have allowed us to move away from the present state to a discussion of origins and evolution.

Why do I call it a "starter pack"? Well, when considering a new topic, all researchers and students need to read a few sections of a good book to familiarize themselves with the relevant background before turning to shelves of journals in the library. There are too few good books of this type around. We must be grateful to Lewis and Prinn for providing another.

Jones's *The Solar System* is a non-mathematical introduction to our planets. I found it rather difficult to visualize the audience it is intended for. We are given a contemporary picture of the planets, with many references to the new data obtained from spacecraft, but the view has been somewhat drained of its excitement. Everything is mentioned, but only briefly and sketchily, and the author has thus given himself little room to point out the problems and mysteries. He has also taken the rather old-fashioned approach of compartmentalizing each planet into a separate chapter, which militates against fruitful comparisons. And now that we are so used to pages of colour images of planets, the reversion to black-and-white produces a sense of disappointment.

There are many general books presently available which deal with the Solar System. Unfortunately, most of them are better than this one. □

David W. Hughes is Senior Lecturer in Astronomy and Physics at the University of Sheffield.

From eye to CCD

Michael Rowan-Robinson

Astrophysical Techniques.
By C.R. Kitchin.
Adam Hilger: 1984. Pp.438. Hbk £40, $65; pbk £15, $25.

IN THE 50 years since Jansky first detected the Milky Way at radio wavelengths there has been a phenomenal explosion in techniques of astronomical observation. The new wavelengths — radio, X-ray, ultraviolet, infrared, microwave, gamma-ray — and the other types of astronomical information reaching the Earth, such as neutrinos, cosmic rays and gravitational radiation, have each required new detection techniques, new types of telescope and new observing platforms, ranging from caverns deep under the Earth to satellite-borne telescopes. Optical astronomy too is being revitalized by new techniques, for example the CCD (charge-coupling device) array and the fibre-optics spectroscope.

Many university and polytechnic departments of physics or astronomy give courses on astronomical observing techniques and instrumentation. Not all of these bear much relation to what is actually happening in astronomy today, and there is a great need for authoritative and accessible books on the subject. Dr Kitchin has set out to provide an account suitable for the science-based undergraduate, though he hopes that the amateur astronomer will find it useful and also points out that increasing specialization in the subject means that most professional astronomers would also benefit from such a book.

Dr Kitchin concentrates on techniques of detection and imaging, but extends this to include the basic optics used in modern telescopes. There is little discussion of the atmospheric and other background limitations which pose such a challenge to observational astronomy and which drive so many of the technical developments. The book is crammed with useful detail, though. It is strongest on the techniques of optical observation: the coverage of the new astronomies such as radio and X-ray is fairly skeletal. Microwave and submillimetre developments are not mentioned. The physical basis of the techniques is briefly discussed, but a fair knowledge of atomic physics and optics is implicitly assumed.

This will be a useful addition to the reading list for a more advanced course on astronomical techniques. But the amateur astronomer may find it a bit heavy going.

Michael Rowan-Robinson is Reader in Astronomy at Queen Mary College, University of London.

Inside the planets

D.C. Tozer

Physics of Planetary Interiors.
By G.H.A. Cole.
Adam Hilger: 1984. Pp.208. Hbk £22, $39; pbk £9.95, $16.

THERE will always be a need for books that try to put the enormous complexity of the known planetary structure and behaviour into a readily comprehended form — books that show a student how much can be explained by a relatively straightforward application of generally accepted physical principles. Professor Cole's book is directed at undergraduates and his choice of subject and approach reflect his background in applied mathematics. For example, much — in my view, too much — attention is given in this introductory text to the gravitational fields and shapes of rotating massive bodies in hydrostatic equilibrium (though who would now deny that a world of meaning and whole fields of research have been inspired by the very small but definite departures of the actual geopotential surfaces from such predicted shapes?). A student needs much more guidance than he is given here for pursuing calculations that tacitly imply a very static view of planetary evolution.

Characteristically, an attempt is made to define the realm of planetary science as that of objects in which self-gravitation is strong enough to induce an axial symmetry of their external shape, but not so strong as to make the atoms "incapable of maintaining the equilibrium which defines a planetary body". Such efforts at classification appeal to the tidy mind, but are likely to prove very confusing to the able and inquisitive student. "Minor planet" is a well-established usage for objects whose light curve suggests a highly irregular shape, and if the quotation I have taken is intended to mean no pressure ionization of atoms, what is one to call an object such as Jupiter, in which a substantial mass fraction is believed to be a pressure-induced metallic phase? Further clarification is not helped by the erroneous comment that free electrons are non-relativistic in planets but fully relativistic in white dwarf stars.

Unfortunately, this kind of ambiguous or poorly reasoned remark is all too common — I noticed serious conceptual errors and typographical mistakes that make the sections on planetary heat transfer and magnetism positively misleading. If there is no treatment of seismology, a chapter devoted to a hydrostatic theory of the structure of icy major planet satellites is an original feature. Nevertheless, I would not recommend this book to students until several corrections have been made. □

D.C. Tozer is a Reader in Theoretical Geophysics at the University of Newcastle upon Tyne.

Eumorphous amorphs

Robert W. Cahn

Physics of Amorphous Materials.
By S.R. Elliott.
Longman: 1984. Pp.386. £25, $60.

ONE of the joys of contemplating amorphous materials is their affinity with paradox. *Amorphous*, etymologically, signifies *shapeless, without form*; yet the book under review has an 80-page chapter on structure. One of the key theorems general to all amorphous solids is the Kauzmann Paradox, which tells us that for all glasses (a concept not quite coterminous with amorphous solid) there is a temperature above 0K at which the entropy must decrease below that of a crystal of the same composition; Dr Elliott offers a careful discussion of the implications of this paradox, which belongs to the category of impossible things that Lewis Carroll's White Queen liked to believe before breakfast.

Again, Dr Elliott repeatedly insists that an amorphous material has no reciprocal lattice, and this poses enjoyable obstacles to theorists who seek to understand, in particular, electron transport in these materials. But even this "reciprocity failure" may not be a universal attribute of amorphous materials, as witness the publication, a few weeks ago, by Shechtman and others, of evidence of a non-periodic metallic phase (a quasicrystal), neither glass nor crystal, which yet gives a sharp diffraction pattern... of fivefold symmetry!

There is a plethora of textbooks and monographs on glasses, but until recently the word has tacitly connoted oxide glasses. A leading exemplar of this large category is *Glass Science* by R.H. Doremus, published in 1973, which is entirely about oxide glasses, an excellent book, subject to that limitation. J. Zarzycki's *Les Verres et l'Etat Vitreux* (1982) takes this classic approach to glass science as far as it will go. Lately, a flood of literature, but no textbooks, about metallic glasses has appeared. Other textbooks again, notably Mott and Davis's celebrated *Electronic Processes in Non-Crystalline Materials*, have covered the theoretical physics of conduction in chalcogenide glasses.

Elliott approaches the field in a new way. He treats amorphous materials quite generally in terms of preparation strategies, ease of glass formation, the glass transition and its statistical mechanics and thermodynamics, and, in particular, structure. That chapter has the clearest exposition of diffuse diffraction from glasses and of EXAFS that I have seen. Defects are also discussed; of course, a genuinely formless material could not possibly have defects, since the existence of defects implies the existence of a non-defective structure! The author pursues a resolutely quantitative approach but combines it with frequent pauses to see where he has got to in terms of a physical model. The reader is thus helped to keep track of the argument. Problems at the end of each chapter, linked always to the relevant mathematics, will help the conscientious reader to cement his understanding.

The heart of the book is a more specialized theoretical treatment of spectroscopy and electron transport, mostly with reference to semiconducting (chalcogenide) glasses but also to metallic glasses. A number of difficult topics are painstakingly set out; I have never seen such a clear discussion of the difficult concept of two-level systems. However, as the author himself specifies, the reader must be competent in solid-state physics somewhat beyond the level of Kittel's *Introduction to Solid State Physics*, and this distinctly narrows the readership.

This fine book has at present no effective rival. Although — inevitably — it barely touches on some aspects of some types of amorphous solid, it is yet an excellent basis for an advanced course on the amorphous state for physicists. □

Robert W. Cahn is currently Visiting Research Fellow at the General Electric R&D Center, Schenectady, New York.

On the ground

C. Kidson

Geomorphology.
By Richard J. Chorley, Stanley A. Schumm and David E. Sugden.
Methuen: 1984. Pp.605. £17.95, $30.
The Nature of the Environment: An Advanced Physical Geography.
By Andrew Goudie.
Basil Blackwell: 1984. Pp.331. Hbk £22.50, $39.95; pbk £7.50, $14.95.
Environmental Systems: An Introductory Text.
By I.D. White, D.N. Mottershead and S.J. Harrison.
George Allen & Unwin: 1984. Pp.495. Hbk £30, $50; pbk £11.95, $19.95.

MORE than 80 years ago, long before the current environmental movement began, geography was described as "the study of man in his environment". However physical geography, environment and geomorphology, as covered by these three volumes, have differing meanings. There is, nevertheless, sufficient overlap to make it useful to look at them together.

In the narrower field of geomorphology, concerned with the geometry of the surface features of the Earth, the new work by Chorley, Schumm and Sugden must be hailed as a masterly review of the development of the science and of its present status and subject matter. It will rank with the classical presentations of Lobeck (1939) and Von Engeln (1948). Its publication may, indeed, come to be regarded as marking almost as significant a stage in the evolution of the subject as the major works of Davis (1909), Penck (1924) and King (1967). Time will be needed to test this view, which some may regard as premature and perhaps extravagant.

The great merits of the book are its balanced presentation of the different ways of looking at the development of landforms and the integration of the historical and functional approaches. Part 1 represents the clearest, most concise and penetrating introduction to the subject which it has been my pleasure to read. While the whole work is clearly aimed at advanced students and professional geomorphologists, this section can be recommended even to first-year students. This is so even though they may not fully comprehend the whole of it and despite the fact that it does less than justice to the studies of denudation chronology, largely carried out by students of that greatest of English Davisian disciples, S.W. Wooldridge. Part 3 is a comprehensive review of contemporary Earth surface processes which brings the advanced student to the very frontiers of research. The remaining sections on geological (Part 2) and climatic geomorphology (Part 4) are penetrating syntheses of these areas of the subject.

The book as a whole is a balanced statement of the present position in geomorphology. The specialist interests of the authors have been combined in a most successful unified approach, and while it is sometimes possible to detect the authorship of particular sections only those very familiar with their individual work will be able to do so.

It is probably unfair to compare this outstanding volume with the new study of the environment by Professor Goudie, which is sub-titled *An Advanced Physical Geography*. This book covers not only geomorphology but includes also climatic and ecological sections and a consideration of man's impact on the environment. Nevertheless, by far the greater part of the subject matter is the same as in Chorley *et al.* In addition, the publishers claim that Goudie's book "is informed by the latest advances in theory and research" and that it "will surely become the standard work". For these reasons alone comparison becomes inevitable.

It has to be said at once that *The Nature of the Environment* suffers in the comparison. It is written in a discursive and descriptive style, with frequent statements of the obvious such as "The great bulk of the world's water is in the oceans" and "During glacials the ice caps of the world were greatly expanded" which one might expect to find in a first year essay. One example serves to show that the publisher's claim for a research basis is somewhat

BioEssays

The current awareness monthly for biological scientists

An ICSU publication

Editor: **W. J. Whelan** *University of Miami*

Presents the results of major discoveries at the very frontiers of molecular, cellular and developmental biology along with the implications for medicine, industry and agriculture

Volume 2: January-June 1985
Volume 3: July-December 1985
Institutional rates: one volume £32.00;
two volumes £63 00
Individual rates: one volume £15 00;
two volumes £28 00
Prices include air-speeded delivery to most countries
ISSN 0265-9247

Published for The British Computer Society

The Computer Bulletin

Editor: **T. F. Goodwin**
Computing Centre, University of Surrey

For the reader interested in the wider world of computing – case studies, industry profiles, news from abroad, features on education, and input from B C S. special interest groups

Series III, Volume 1 Quarterly from March 1985
U.K. £6 00; Overseas £7 00 *ISSN 0010-4531*

The Computer Journal

Editor-in-Chief: **P. Hammersley**
Computer Centre, Middlesex Polytechnic

Technical, commercial and academic papers for specialists in all aspects of computer science.

Vol. 28 Quarterly from February 1985 – plus an additional issue in April 1985, to be included in the subscription price
U K & Eire, £95.00, Overseas £110.00 *ISSN 0010-4620*

SPECIAL OFFER: 1985 subscribers to the Journal will receive the four 1985 issues of the Bulletin free of charge

Coming later this year:

Chemica Scripta

Published for the Royal Swedish Academy of Sciences

Editor-in-Chief: **Salo Gronowitz**
University of Lund, Sweden

Covering all aspects of physical, organic and inorganic chemistry. Special first issue entitled Hydration Forces and Molecular Aspects of Solvation

Vol. 25 Quarterly from March 1985 plus annual Nobel Symposium supplement £95 00, residents of Sweden only, £71 25 *ISSN 0004-2056*

Journal of Tropical Ecology

Published for INTECOL and the ICSU Press

Editor: **Adrian G. Marshall,** *Institute of South-east Asian Biology, University of Aberdeen*

Research reports and reviews on topics in the general field of ecology of tropical regions

Quarterly
£15 00 (institutions), £18 00 (members of INTECOL)
ISSN 0266-4674

International Journal of Technology Assessment in Health Care

Editors: **Egon Jonsson** *Karolinska Institute*; **Stanley J. Reiser**
University of Texas Health Science Center

Investigating the interface between health care providers, decision makers, and academics concerned with the role of technology

Quarterly
£35.00 (institutions), £18 00 (individuals)
ISSN 0266-4623

Water Science Reviews

Executive Editor: **Felix Franks,**
Department of Biology, University of Cambridge

Yearbook of basic and applied research on water and the role played by aqueous solvents in physical, chemical, biological, technological and environmental processes

Annual £24 00 *ISSN 0266-4615*

CAMBRIDGE

The Cambridge Guide to the Material World

RODNEY COTTERILL

This provides a unique single-volume description of all the materials, both animate and inanimate, in the terrestrial environment. The book stresses the essential unity of nature at the atomic level and is liberally supplied with beautiful full-colour photography and illustrations throughout.

The text is littered with fascinating analogies and examples, and topics requiring special attention are highlighted in display panels. Text and illustrations are carefully integrated to ensure maximum readability, and each chapter ends with a clear summary of what has gone before.

Circle No.44 on Reader Service Card.

Communicating in science: writing and speaking

VERNON BOOTH

Writing scientific papers and giving talks at meetings and conferences are essential parts of research scientists' work, and this short, straightforwardly written book will help workers in all scientific disciplines to present their results effectively.

The first chapter is about writing a scientific paper. Later chapters discuss the preparation of typescripts, speaking at meetings and writing theses. There are special sections for non-English speaking scientists and for Americans. The last chapter gives information about dictionaries, style books and other literature.

overdrawn. The short and inadequate section on sea level changes shows no acquaintance with the work, between 1974 and 1982, of the International Geologic Correlation Project No.61, on sea level change in the last 15,000 years. Similarly the claim that it will become the standard work looks somewhat exaggerated in the light of a reference list confined solely to textbooks. In short, the book has some merit as an introduction to the subject but is not for advanced students and research workers.

The last of this trilogy, *Environmental Systems*, is a modest approach to the very

U.S. Department of the Interior

Subject for the geomorphologist — the Grand Canyon, drawn c. 1880 by William H. Holmes.

broad subject of "the environment". As an introductory text, which it claims to be, it has much to offer. Unlike Chorley *et al.* the authors do not set out to embrace, or even to reconcile, all approaches to their subject matter but concentrate firmly on the single methodology of their title. In this the book is very largely successful. A careful factual exposition is supported by frequent references to source material, by detailed suggestions for further reading and by a bibliography of 350 journal references. It is a little disappointing that Part C does not include any treatment of coastal environments — the book's aim to promote "an understanding of Man's terrestrial environment" surely cannot be entirely achieved if it ignores a part of it where such a large number of people live and work. Despite this shortcoming this is a successful book and one which can be recommended to the readership at which it aims.

The strength of interest in "the environment" is shown by the steady flow of publications in this general field at all levels. Occasionally an outstanding book in a specialized part of the subject appears and tends to overshadow other worthwhile contributions. *Geomorphology* by Chorley, Schumm and Sugden is such a work. Still, the other volumes reviewed here also have their strengths and will be of value to somewhat different readerships. □

C. Kidson is Emeritus Professor of Physical Geography at the University College of Wales, Aberystwyth.

Devonian review

Bruce Sellwood

Aspects of a Stratigraphic System: The Devonian.
By D.L. Dineley.
Macmillan, London: 1984. Pp.223. Hbk £20; pbk £9.95.

THE Devonian Period spans some 48 million years (408-360 Myr) and was originally established, in Devon, as the Devonian System by the entrepreneurial stratigraphic approach of Sedgwick and Murchison in 1839. David Dineley, who has devoted many years to research on the Devonian and its fish faunas, has written this book to illustrate, he says, the ways in which the different disciplines within geology help our understanding of how things were 360 million years ago. He claims that it is aimed at the "interested" but "not very advanced student of historical geology".

The book doesn't really provide a source on regional Devonian geology (though in fairness one should say that it doesn't set out to do so); thus it cannot be used in the same way as Arkell's masterly descriptive account, *Jurassic Geology of the World* (Oliver and Boyd, 1956). Neither does it provide an ideas approach to a system comparable with that of Hallam's *Jurassic Environments* (Cambridge University Press, 1975). Instead it falls somewhere in between.

The introduction attempts to justify use of the Devonian as a vehicle for the book "because it is there", an argument that also recurs in subsequent chapters on the materials of stratigraphy, and stratigraphy and the world tectonic model. In the latter, plate tectonic models are extensively adopted from the literature, although being considered "crude means of solving problems in crustal history". The next chapter ("Time in Question") shows how stratigraphic correlation is achieved, while Chapter 5 deals with biostratigraphy and reviews the various groups of organisms found in Devonian rocks and their use in correlation.

The following four chapters deal with Devonian facies: Old Red Sandstone; paralic facies (including some carbonates); carbonates and evaporites; and deep-water suites. Each begins with a generalized global review before giving brief accounts of individual areas (Arctic Canada, western Europe, the Russian Platform, Altai-Sayan, east Asia and so on). Many maps are included (though only a single isopachyte map occurs in the whole book), but relatively few stratigraphic sections. This is a pity in view of the fact that, after correlation, successful stratigraphic interpretation rests on the details of sequence evaluation.

Finally, Dineley considers Devonian geography, particularly covering recent work on possible continental dispositions, facies and the oceanographic implications. Climatic changes are reviewed and notions of meteorite impact speculated upon.

I'm unsure about the readership for this book. It cannot really be for "interested" students, because they will get lost in the sections on biostratigraphy; and it won't be for the specialist Devonian workers because this is a broad scale review. Still, it should be taken up by university libraries where it will be a useful student text for the few sessions normally spent on Devonian geology. □

Bruce Sellwood is a Lecturer in Geology at the University of Reading.

Earth through time

A. Hallam

The History of the Earth's Crust.
By Don L. Eicher, A. Lee McAlester and Marcia L. Rottman.
Prentice-Hall: 1984. Pp.197. Hbk $25.60, £23.30; pbk $22.90, £20.85.
The Evolving Continents, 2nd Edn.
By Brian F. Windley.
Wiley: 1984. Pp.399. Hbk £25, $24.95; pbk £9.95, $21.50.

IN THE current enthusiasm to understand more about geological processes in such diverse fields as sedimentation, rock deformation and volcanism, increasing use is made of mathematical modelling and modern laboratory techniques. This analytical approach remains somewhat sterile, however, if it fails to illuminate Earth history, which remains at the core of academic geology. Because the subject is so complex and involves synthesis of a diversity of rapidly growing research fields, satisfactory undergraduate textbooks are few and far between. As in other spheres of science the premium in research is on increased specialization and this inevitably influences what is taught in university courses.

The advent of the new book by Eicher, McAlester and Rottman is to be welcomed because, within its limitations, it copes very well with a difficult task. The principal limitation is one of brevity; the book forms part of a Prentice-Hall Earth Science series which is restricted to short, small-format books. The text is clearly written in plain, straightforward English and there are plenty of good illustrations. After an initial outline of stratigraphic principles and geochronology the authors deal with the Earth as a planet in a way more customary in physical geology texts, before devoting successive chapters to the Precambrian, Palaeozoic, Mesozoic and Cenozoic.

The writing is thoroughly up to date, whether dealing with subjects as different as Precambrian life and the cause of mass

extinctions, suspect terrains or orbital cycles as a cause of ice ages. The principal shortcoming is that the book is written at a very elementary level and has a minimal bibliography. There is little critical evaluation or in-depth treatment of specific subjects, and detailed examples are taken almost exclusively from the United States. This is essentially an Earth history digest aimed at the large American freshman and sophomore market; in consequence, it is unlikely to be adopted widely for geology honours courses in British universities, where world history is normally dealt with at a comparatively advanced level after a thorough grounding in stratigraphic principles has been undertaken with reference to local examples.

For the past eight years the most suitable textbook for senior undergraduates has been Windley's *The Evolving Continents*, in which a pioneering attempt was made at an overview of continental evolution from the Archaean onward, within a conceptual framework of plate tectonics. Windley's book has been a well warranted success and the second edition is timely.

So rapid have been the advances of recent years that substantial revision has proved necessary, though the basic outline remains unchanged. The new Harland timescale is adopted uncritically in a new opening chapter. It is perhaps as well that Windley did not wait a further couple of years before revision, because he would then have had three other new timescales to contend with, all differing in some important respects. Besides major changes in the Precambrian chapters there are new sections for the Phanerozoic on a host of subjects. These include, among many others, phosphorites in relation to oceanic upwelling, mass extinctions, the Iapetus Ocean, the elevation and climate of Pangaea, oceanic mineralization, Pacific island arcs, suspect terrains and the structure and evolution of the Himalayas. The bibliography remains at 30 pages but the contents are much changed.

As in the first edition, Windley is at his most authoritative when dealing with tectonics, especially the Archaean and Proterozoic, though he is not sufficiently up to date to record that much of eastern Asia is now thought to consist of isolated continental fragments brought together since the late Palaeozoic. On subjects such as palaeoenvironments, or those dealing with events in the biosphere, he is less comprehensive and reliable. The big advances recently in the understanding of sedimentary basin formation and continental margin subsidence are largely ignored, and Phanerozoic sea-level changes receive only a scant treatment. It would, however, need a superman to produce an advanced textbook of Earth history that was equally strong in all fields. □

A. Hallam is Lapworth Professor of Geology at the University of Birmingham.

Student pollution

Peter S. Liss

Fundamentals of Air Pollution, 2nd Edn.
By Arthur C. Stern *et al.*
Academic: 1984. Pp.530. $39.50, £28.
Pollution of our Atmosphere.
By B. Henderson-Sellers.
Adam Hilger: 1984. Pp.210. Hbk £30, $49; pbk £13.95, $23.

AIR POLLUTION is a fast-moving topic which has attracted much public attention in recent years. Developments in it have often been haphazard since, instead of a steady flow of funding for research, there has been a tendency to throw large amounts of money at particular problems, for example acid rain, and halocarbons and their possible impact on stratospheric ozone. With this sort of patchy temporal progress it might be thought that there would be widespread disagreement as to what should be included in the corpus of knowledge constituting the subject. However, to judge from these two books there is apparently considerable unanimity as to what courses in air pollution in higher education should contain. Basically both of them deal with sources, effects, measurement, monitoring, meteorology, and regulatory and engineering control of air pollution. But there the similarity ends.

The book by Stern *et al.* is a new edition of a publication of the same title which appeared 11 years ago. Two of the original four authors remain and two new ones have been recruited. The style and level of the new edition are much as previously, but the text has not merely been revised and considerable parts of it are completely new. Even so, there is a less than modern air about it, a possible reason for which will be discussed shortly. Students will find the book packed with information and it will serve them not only while they are at college but also in any subsequent career concerned with atmospheric science.

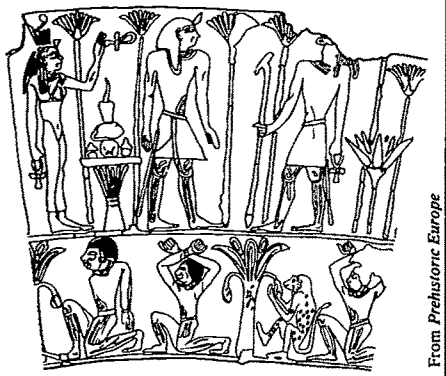
Henderson-Sellers's book is definitely a new production but again it doesn't strike me as really being at the forefront of knowledge. It is readable and a real attempt is made to explain how physical processes operate in the atmosphere, rather than merely stating that they do, as is done in less didactic treatments. The book is quite short and students should find it a good read, though I'm not sure it will be as useful to them after graduation as will Stern *et al.*

My principal grouse about both books is their lack of treatment of atmospheric chemistry. Both attempt to deal with chemical aspects of the subject but the approach is peripheral rather than central. Of the two, Stern *et al.* does a better job in this regard but even here the chemistry has insufficient weight. Because of this, important topics such as removal of air pollutants by natural cleansing processes, hydroxyl chemistry, and even acid rain receive only scant attention. It is the underplaying of chemical aspects which I believe gives both books a somewhat dated air. Arguably the biggest growth area in air pollution research in the past decade has been in atmospheric chemistry. Books in which insufficient attention is paid to this will inevitably look old before their time. □

Peter S. Liss is Reader in the School of Environmental Sciences at the University of East Anglia.

Archaeology anew

Colin Renfrew



Prehistoric Europe.
By Timothy Champion, Clive Gamble, Stephen Shennan and Alasdair Whittle.
Academic: 1984. Pp.359. Hbk $45, £28.50; pbk $23.50, £14.50.

WHEN a discipline has recently undergone a profound, perhaps revolutionary transformation, the first textbook to follow that upheaval is of more than usual significance. The study of European prehistory has indeed undergone such a transformation over the past 15 years, with the widespread acceptance of a chronological system very different from that which prevailed earlier, and with the development of interests and forms of explanation which were not much in evidence then. This ambitious volume offers the first reasonably comprehensive overall coverage of the resulting subject, from the palaeolithic period to the iron age.

Three qualities separate the prehistoric archaeology of today from the traditional version, seen in a series of standard works from V. Gordon Childe's *Dawn of European Civilisation* (first edition 1925) to Stuart Piggott's *Ancient Europe* (1965). The first is the happy lack of preoccupation with chronology: radiocarbon dating has now successfully solved many of the outstanding chronological problems. So that while the early works of the new radiocarbon era were backed up by bulky appendices of date lists, much needed at the time, these are absent here. A second feature is the refreshing absence of automatic diffusionist assumptions: no longer is it taken as self-evident (whether by explicit axiom or by unstated convention) that most changes in the prehistoric record came about as the result of contacts with the civilized lands of the Near East by a process of the "diffusion" of culture. And thirdly, the processual approach now predominates: that is to say the emphasis is on the explanation of change through an analysis of economic conditions and social structures. The discussions of change in

this volume are lively and interesting, and in some cases new and original as well.

The book is the collective work of four authors: justifiably so, for there is no one today who could cover the subject single-handed with the same authority. Indeed perhaps there never was, for the earlier textbooks in general did not venture very far back into the palaeolithic period. Inevitably, however, in the necessary work of compression some detail is lost. We no longer see the comprehensive summaries of pottery styles and of the artefact forms

From *Prehistoric Europe*

Pictures of the past — decoration on a vase dating from the late eighth or seventh century BC found at Tarquinii in Etruria.

which occupied so large a proportion of many earlier accounts. Instead the themes treated are sometimes at a further remove from the raw data. In consequence this book will perhaps be more vulnerable to change as problems come to be solved and new questions arise. But, in a sense, the better the textbook the more rapidly will it be affected by the progress of current research.

The book is well-organized chronologically, and the treatment wisely takes the survey down to the beginning of the modern era (the BC - AD interface) for Europe as a whole. The emergence of the civilization of classical Greece thus falls within its scope, together with that of the Etruscans of Italy. This presents problems of treatment, which many earlier authors have avoided, since of course the availability of written sources brings Greece out of prehistory and into the light of history at that time, and the summary offered here will no doubt find its critics. But the solution is a bold one, and I find it altogether effective.

Minor faults and failings in several places can be rectified in a second edition. Meanwhile it is a pleasure to salute the appearance of a survey which for the first time since the New Archaeology of the 1960s presents the prehistory of Europe in a coherent and satisfying way. It will at once take its place as a new standard work, for it is quite simply the best introduction to European prehistory which is currently available. □

Colin Renfrew is Disney Professor of Archaeology at the University of Cambridge, and a Fellow of St John's College, Cambridge.

Fossil selection

W.S. McKerrow

Atlas of Invertebrate Macrofossils.
Edited by John W. Murray.
Longman/Halsted: 1985. Pp.241. Pbk £13.95, $24.95.

IT IS very seldom that I have opened a new book with such delight. About half of its pages consist of magnificent photographs of well-preserved fossils, and primary congratulations must go to the photographers who have so ably produced these illustrations. The preface informs us that there are about 3,000 named minerals, but that the invertebrate macrofossils include tens of thousands of genera and hundreds of thousands of species. It has never been easy to select what to teach from this myriad. Now we have a choice of 900 well illustrated fossil genera, more than enough for an undergraduate course. Some of my favourite genera are missing, but most are there; more significantly only one or two minor groups of macrofossils are absent: hyolithids and archaeocyathids seem to have escaped the editor's net. (Vertebrates and microfossils are also absent, but by deliberate decision. Do they warrant two more books along the same lines?)

Seven of the contributors are from British universities, five from the Natural History Museum, one from the Geological Survey of Greenland and one from Brigham Young University, Utah. They all know what is needed to give authoritative descriptions of the common fossil groups. Although there is some bias towards north-west Europe, the fossils illustrated and described include genera from all over the world. So the book will be a useful text for any student in any country who can read English, while the diagrams and photographs should even prove helpful to those with only a scanty knowledge of the language.

Most chapters include a glossary of descriptive terms, and also an evolutionary diagram showing the relationships of the larger taxonomic groups. But, as the editor points out (p.2), "taxonomy is not the main aim of palaeontology. It is the application of correctly identified fossils to the problems of biostratigraphy and palaeoecology which makes palaeontology a major part of geology". The teacher who uses this book in class will still have plenty of work to do, especially in explaining the biology, ecology and evolution of these extinct animals. However, this atlas will make his task (and that of the student) so much more pleasant and so much more efficient. □

W.S. McKerrow is a Lecturer in the Department of Earth Sciences, University of Oxford.

A view of solids

R. Rudham

Solid State Chemistry and its Applications.
By Anthony R. West.
Wiley: 1984. Pp.734. £37, $67.95.

HAVING carefully defined solid state chemistry as the synthesis, structure, properties and applications of solid materials, the author of this book is somewhat confined within a straitjacket of his own manufacture. Unfortunately, his definition precludes consideration of the important interactions between solids and gases or liquids. The fact that the book has nothing to say about adsorption and heterogeneous catalysis is perfectly acceptable, but when metal oxidation is similarly ignored one cannot help questioning the desirability of such a definition of solid state chemistry.

The non-mathematical approach adopted by the author contributes to the readability of his work, but inevitably introduces some shortcomings. For example, the law of mass action treatment given for lattice defect equilibria is less informative than that of statistical thermodynamics, where the compensating contributions to the overall free energy from defect formation and configurational entropy are directly seen. Nevertheless, the chapters on structure and properties present an interesting and coherent account of these fundamental aspects.

What is less certain is the merit of the last four chapters on glasses, cements, refractories and organic solids, when serious consideration of diffusion processes and solid state chemical reactions has been omitted. In particular, the final chapter on the organic solid state seems something of an afterthought and in its brevity unjustly emphasizes the inorganic nature of the subject. To be fair, the early chapter on synthetic methods presents information on chemical reactions involving solids, but also injudiciously absolves the book from consideration of their kinetics. It is in this chapter that one of the major founders of modern solid state chemistry, Carl Wagner, receives his only mention.

West has written a remarkably readable account of solid state chemistry as he sees it, but who will read it? Both size and price will preclude its formal adoption as an undergraduate text, although it should make the recommended reading lists. Postgraduate students and other researchers will find it gently informative on areas other than those of their personal endeavours. The most probable readership will be non-chemists who have reason to enquire into the nature and physical behaviour of solids at the atomic level. □

R. Rudham is a Reader in Physical Chemistry at the University of Nottingham.

Different elements to chemistry

Jon McCleverty

Inorganic Chemistry: Principles of Structure and Reactivity, 3rd Edn.
By James E. Huheey.
Harper & Row: 1984. Pp.936. Hbk $37.50; pbk £11.50.
Chemistry of the Elements.
By N.N. Greenwood and A. Earnshaw.
Pergamon: 1984. Pp.1,542. Hbk £75, $120; pbk £19.50, $34.95.
Structural Inorganic Chemistry, 5th Edn.
By A.F. Wells.
Clarendon: 1984. Pp.1,382. £75, $98.

OF THE three books reviewed here, two are, to most inorganic chemists, old friends (Huheey and Wells), and one is a keenly anticipated newcomer. The books by Huheey (now in its third edition) and Greenwood and Earnshaw are intended as student texts, whilst that by Wells (a fifth edition) is primarily a work of scholarship and reference directed at one aspect of inorganic chemistry — the structure of crystals and solids of all types.

I have always been an admirer of Huheey's account of the principles of structure and reactivity in inorganic chemistry, largely because, like my students, I found it immensely readable and a nicely presented package of material for the core of the first two years of an undergraduate course. Typically North American in its approach, combining a distinct flavour of the physical chemist's view of chemistry, nonetheless it advances inorganic chemistry within a topic approach which makes the consumption of a wide range of facts both appetizing and digestible.

The early chapters deal with atomic structure, bonding models, chemical forces, acid–base chemistry and chemical behaviour in aqueous and non-aqueous media. It is gratifying to see a chapter on solid-state chemistry, although perhaps rather small in the light of the rapid growth of interest in the subject. Later chapters are concerned with coordination chemistry in all its aspects, organo-transition metal chemistry (including ritual obeisance to homogeneous catalysis) and bioinorganic chemistry. There are three chapters covering some descriptive chemistry of the d- and f-block metals, and of the halogens and rare gases. This is an improvement over the earlier editions, although there are, inevitably, still quite significant gaps. To some extent, however, the omissions are partly catered for in the excellent chapter on periodicity. The appendices contain a wealth of physical data, and discussions of nomenclature and of group theoretical symbolism and symmetry (although this is not used specifically in the text).

Greenwood and Earnshaw provide a wholly different menu of inorganic chemistry, returning in a sense to a factual presentation based on single elements or groups of elements following the periodic table. Thus the s- and p-block elements take up most of the first half of the book, and transition metals, reported by vertical groups, the second half. The only time that topics are discussed is at the beginning — the origin of the elements, isotopes and atomic weights, and chemical periodicity and the periodic table — and later with an account of coordination chemistry which precedes discussion of the transition metals.

Within each chapter, the properties of the elements and their compounds are discussed systematically, and aspects of solid state, organometallic and bioinorganic chemistry are referred to at the appropriate point. An unusual and unexpected feature is the inclusion in the chapter on carbon of a major discussion of metal carbonyl and hydrocarbon chemistry, particularly from the structure and bonding point of view. But by far the most interesting and novel feature of this book is the liberal presentation of facts and figures on the uses and potentially useful properties of inorganic compounds, information which is almost totally absent from any other major texts in this subject area. The danger of including such material is, of course, that it may rapidly become out of date, but that problem apart this is a fresh approach to the furthering of the relevance of inorganic chemistry which is to be welcomed enthusiastically.

It is not helpful to say which of the two books one might choose as the basis for a course of inorganic chemistry at the tertiary level. Huheey is certainly appropriate for the first two years of a British undergraduate curriculum, and I suspect that students would prefer it initially as a more helpful study guide. However, Greenwood and Earnshaw's book unquestionably contains more chemical information, and course instructors will be immensely grateful to the Leeds chemists for having reminded us all that facts are facts, whereas theories often reflect passing fashions and fancies.

Wells's *Structural Inorganic Chemistry* cannot be realistically regarded as a student text, although senior undergraduates will undoubtedly use it for reference. It seeks to present the structural basis of inorganic chemistry for chemists, and it succeeds. It is a little bit like an Irish stew — everything is included, cooked in a special and uniform way, making up a rather fine and nourishing dish.

The book is divided into two parts, the first of which deals with a number of general topics, including the properties of polyhedra, the nature of symmetry and repeating patterns, the way in which spheres of varying sizes pack together, and bonding in molecules and crystals. The second, longer part describes the structural chemistry of the elements, based on the groups of the periodic table. Here oxides, hydroxides, aquo species, sulphides and halides receive considerable attention, but there are also chapters dealing with metal carbonyls, carbides and alkyls, the coordination chemistry of the later transition metals, and metals and alloys. The text is usefully referenced and there are formula and subject indexes.

In a subject as vast as structural inorganic chemistry, encompassed in some 1,400 pages of text, there are bound to be some topics which receive only cursory treatment. However, this is likely to worry only the crystallographer rather than the broader congregation of chemists, and the author is to be congratulated on assembling such an amount of useful information in such an accessible form. □

Jon McCleverty is Professor of Inorganic Chemistry at the University of Birmingham.

Organic affairs

John Mann

Advanced Organic Chemistry, Part A, 2nd Edn: Structure and Mechanisms.
By Francis A. Carey and Richard J. Sundberg.
Plenum: 1984. Pp.726. Hbk $59.50, £56.53; pbk $16.95, £16.19.
Organic Chemistry.
By G. Marc Loudon.
Addison-Wesley: 1984. Pp.1,451. $39.95, £39.
The Third Dimension in Organic Chemistry.
By Alan Bassindale.
Wiley: 1984. Pp.242. Pbk £7.95, $17.95.
Spectral Problems in Organic Chemistry.
By R. Davis and C.H.J. Wells.
Chapman & Hall/Methuen: 1984. Pp.121. Pbk £5, $10.95.

LIKE Shakespeare's *Henry IV*, *Advanced Organic Chemistry* by Carey and Sundberg comes in two parts. Last year (*Nature* **308**, 136; 1984) I extolled the virtues of the second edition of Part B, which is concerned with the methodology of organic synthesis. Part A deals with structure and mechanisms and, like its companion volume, is aimed at the advanced undergraduate or novice graduate student.

The style is modern, and both molecular orbital theory and the frontier orbital approach are used to good effect. There is a lot of physical organic information pertaining to the various reaction types, and other highlights include chapters on stereochemical principles and conformational analysis, concerted reactions and photochemistry. The numerous problems provided are well-chosen, and many contain data taken from the research literature.

Overall, the book complements Part B

most satisfactorily — the one providing the theory, and the other the practice. There is, however, a rival text of the same title by Jerry March, published by McGraw-Hill, a third edition of which is due later this year. March has become an essential purchase for many graduate students, especially for its vast collection of literature references. Carey and Sundberg's books are more readable and much better illustrated, but are not so well endowed with references. Any decision between the two types of book will depend upon personal preference and the size of one's bank balance (assuming that one book costs less than two).

At a lower level there are now so many books on organic chemistry that any new contender must offer something different in order to succeed. Recent innovations include two-tone illustrations, comprehensive chapters on spectroscopic methods and sections on "special topics". In his book, Loudon incorporates the first two of these, but spurns the last, somewhat gimmicky one.

Most books of this kind commence with the alkanes and introduce mechanistic concepts through a consideration of free radical processes. In contrast, Loudon believes that the "curly arrow" formalism and heterolytic processes should be used as an introduction to mechanistic organic chemistry, and I suspect that many would support this. Two-tone illustrations are used to good effect, not only for mechanisms but also whenever emphasis is required, as, for example, in the chapter on NMR spectroscopy. This appears early in the book, and stresses the practical uses (with lots of examples) rather than the theory. The links with life processes are not forgotten, so we find biological oxidation alongside oxidation of alcohols; ionophore antibiotics in with the ethers; and the mode of action of S-adenosyl methionine as an example of sulphonium chemistry. In fact the chapter on organosulphur chemistry is more extensive than in any other recent text of this kind, and reflects modern usage of these reagents. The same can be said of the account of heteroaromatic species. Other nice touches include examples of experiments, amusing historical anecdotes and end-of-chapter summaries.

There are, however, some important omissions — for example pericyclic reactions and organophosphorus chemistry — and there is a rather limited treatment of the strategy of organic synthesis. In these respects Streitwieser and Heathcock's *Introduction to Organic Chemistry* (Collier Macmillan/Macmillan 1981) is superior. Omissions apart, Loudon's book is beautifully presented, has lots of interesting problems and is very readable.

The Third Dimension in Organic Chemistry by Alan Bassindale is not an easy read, but the effort is well rewarded. It is much more than a text on the shapes of carbon compounds, and covers all of stereochemistry including the dynamic aspects. The book is divided into three almost equal parts, and commences with a section on general stereochemical principles which takes the reader from a pre-university level as far as elementary conformational analysis. Part 2 deals with conformations of acyclic and cyclic systems and introduces the concept of chirality. This prepares the reader for the meatiest part of the book which covers the stereochemical features of the main reaction types. Substitution, addition and elimination reactions are discussed in detail, and there is also a chapter on pericyclic reactions. Finally, the concept of asymmetric synthesis is introduced and this is most pertinent since so much modern synthesis is concerned with the quest for stereochemically pure products. This chapter should perhaps have been longer, however, with a few more practical examples, such as the use of metal enolates or chiral hydrazones in asymmetric synthesis. One other suggestion for the second edition would be the provision of a decent stencil for the chair conformations depicted! Otherwise, the book is an excellent introduction to stereochemistry and should become very popular.

This should also be true of the book by Davis and Wells, which provides 56 spectral problems at a cost of about 9p a time. Infrared, NMR (proton and ^{13}C) and mass spectral data are given for each compound, and in most cases an elemental analysis is also supplied. The answers are given in the form of references to *Beilstein*, the *Merck Index*, the *Dictionary of Organic Compounds* or to Aldrich's chemical catalogue. The spectra are reproduced well and the problems are both interesting and demanding; this book is especially welcome because interpretation of spectra (in particular NMR spectra) is nowadays central to most courses in organic chemistry. □

John Mann is a Lecturer in Organic Chemistry at the University of Reading.

Textbook supplement — prices

Where possible both dollar prices in the United States and sterling prices in Britain are given in the bibliographical details for each book. Export prices will generally be higher. If a dollar or sterling price is not cited, the book is not available in one of the two countries. However readers should check both price and availability of books before ordering.

Metabolic change

M.L. Sinnott

Essentials of Bio-organic Chemistry.
By R.W. Hanson.
Edward Arnold: 1984. Pp.208. Pbk £6.95, $14.95.

OVER the past four or five decades, the application of chemical techniques and concepts to biology has proved one of the most fertile fields of scientific endeavour. Undergraduates in the biological sciences should now, ideally, have a firm grounding in those areas of chemistry germane to their studies: thus biochemists should understand the chemical logic behind metabolic transformations. Dr Hanson has taken "bioorganic chemistry" to mean the material necessary for an understanding of the chemistry of the transformations of organic metabolites *in vivo*.

The ground the book attempts to cover is very well chosen — a treatment of the properties of biologically occurring functional groups, uncluttered by the recondite technology of Synthesis, is followed by chapters on enzymes and coenzymes. However, in execution the text is a catastrophic failure with serious errors of fact and comprehension throughout.

For example, we read that "in general all positively charged electrophiles are more powerfully electrophilic than neutral compounds" (p.24); that ΔG^* ($\Delta G^{\ddagger}$?) is "a measure of the energy which must be associated with a collision between A and B" (for reaction to occur) (p.28); that "oxidations are invariably associated with a large negative value of ΔG" (p.36); that, in the context of *aliphatic* diazonium ions, aromatic diazonium ions undergo nucleophilic displacements "for example, with iodide ions" (p.75); that "the 'entropic effect' of enzymes may cause rate accelerations of 10^8" (not 10^8M); and that "electronic catalysis might contribute a further factor of the order of 10^2" (p.154). Dr Hanson's treatment of additions to the carbonyl group (p.87 ff.) is innocent of any mention of general acid–base catalysis, his discussion of prochirality does not distinguish between enantiotopic and diastereotopic groups, and the concept of transition state analogues materializes without explanation from "application of transition state theory to . . . enzymes" (p. 164).

Although wholly inadequate in matters of substance, the text pays much attention to nomenclature and IUPAC names are used for small molecules (propanone for acetone, 2-amino acids for α-amino acids): of course this scientific Volapük is impracticable for large biological molecules, which are still called by the names people use. So we see "methanoic acid" on p.103 but "formyl methionine" on p.107.

The standard of scholarship of this text holds a moral for those of our political masters who wish to grind down more of the tertiary education system to a "teaching only" function. Even if an academic has the insight to identify a real educational need — as Dr Hanson has done — that need is most unlikely to be filled unless the academic has a substantial research presence in the area concerned. □

M.L. Sinnott is Reader in Bioorganic Chemistry at the University of Bristol.

Animals illustrated

D.R. Newth

Integrated Principles of Zoology, 7th Edn.
By Cleveland P. Hickman Jr, Larry S. Roberts and Frances M. Hickman.
Times Mirror/Mosby/Blackwell Scientific: 1984. Pp. 1,065. $34.95, £38.
General Zoology, 6th Edn.
By Claude A. Villee, Warren F. Walker Jr and Robert D. Barnes.
Holt Saunders/Holt, Rinehart & Winston: 1984. Pp.992. Hbk £22.95, $36.95; pbk £18.95.

EACH of these texts is about thirty years and half-a-dozen editions removed from its first appearance. Each is the work of three authors who acknowledge help in revision from many sources. Each is large and lavishly illustrated, devotes its largest single section to a systematically arranged account of the animal kingdom, but gives over half its total length to sections on behaviour, cell biology, ecology, genetics and physiology. Both sets of authors, in fact, have tried to include in one volume the minimum background of chemical and biological science necessary to make sense of any, or all, forms of animal life. In consequence they have had to be sparing in their descriptions of actual animals. The balance struck in both books is, I think, about right for texts at this level.

It would be surprising if many of the idiosyncracies, personal opinions on matters in dispute, or even the occasional lapses in matters of fact or of taste which endear the single-author book to the reader, could survive the editorial process in a middle-aged text produced for large numbers of undergraduate students. These losses are the price we pay for a gain in reliability and for a reduced danger of major omission. These two books, having set out with similar aims, have adopted broadly similar methods and have succeeded to much the same extent.

However the two are not indistinguishable. Hickman *et al.* is the more relaxed in tone, the more generously produced and, perhaps, the more willing to comment, from the zoologist's point of view, upon matters of public or lay interest. Thus the book ends with a chapter on animals in the human environment which gives a balanced but forceful treatment of the need to adopt conservation measures worldwide and without delay. Old-fashioned textbooks might mourn the extinction of species, but would hesitate to quote specific legislation and litigation in describing any one case. The story of the attempts to save the snail darter from the effects of building the Tellico dam may well serve to excite more interest in that unfortunate fish than it would ever otherwise have received.

Hickman *et al.* is the more colourful book in the literal sense, using colour photographs freely and sometimes to pleasing effect. Whether or not this always adds to the value of the illustration is perhaps doubtful. It also evades the modern publisher's unhappy proscription of footnotes by allowing use of the wide margins of the printed page for "marginal notes" in which additional or peripheral matter can be added without stemming the flow of the main story. A similar, but less sightly, trick is used by Villee *et al.* who place such matter in "boxes" which can take up much of the page. This apart Villee *et al.* is altogether more reserved in presentation, both visually and in the text. It provides a businesslike account of its material, but must be faulted for a rather cavalier treatment of some important areas. Parasitology, the insects of economic importance, indeed the insects as a whole, and regeneration are cases in point. While my own preference would be for the more lively and imaginative approach of Hickman *et al.*, there is not a great deal in it. □

D.R. Newth was formerly Regius Professor of Zoology at the University of Glasgow.

Aspects of insects

M.E.G. Evans

Insect Biology: A Textbook of Entomology.
By Howard E. Evans.
Addison-Wesley: 1984. Pp.436. $32.95, £14.95.
Insect Physiology, 8th Edn.
By V.B. Wigglesworth.
Chapman & Hall/Methuen: 1984. Pp.191. Hbk £15, $35; pbk £7.95, $15.95.

INSECTS are now studied as living animals rather than as stamps in collections, and this changed attitude is reaching student texts. Both of these books deal with insects as living organisms: their forms, functions and lifestyles. The first book is a fairly large general text, which concentrates particularly upon the behaviour, physiology and ecology of insects, whilst the second is a concise introduction to their physiology.

Some years ago, H.E. Evans wrote what was probably the best recent book on insects which was comprehensible to the general public (*Life on a Little-known Planet*, published by Dutton in 1968), so I received his textbook with great interest and anticipation. In fact, this is a multi-author work, as Evans has five colleagues as co-authors, but the style is consistent and a high standard of clarity is maintained throughout.

The 18 chapters are grouped into seven parts dealing respectively with structure and diversity, functions and development, behaviour, plant–insect relationships, relationships with animals, ecology and pest management. There is also an appendix on non-insectan Arthropoda which is followed by a useful glossary. Each of the chapters concludes with a summary followed by "selected readings"; these include the most pertinent references, but might have been longer and more comprehensive. With few lapses, the text is written simply and informatively, and the illustrations are mostly straightforward line diagrams which are neatly boxed to separate them from the text. The traditional entomological preoccupations with morphology, taxonomy and diversity have been condensed into the first section to allow for expansion of the later parts.

Wigglesworth's book is a new edition of a well-established work; indeed, there can be very few authors who have produced a new edition of their book a full half-century after the original date of publication. It covers the traditional range of insect physiology by describing the operation of the various organ systems (many of which have been elucidated by Sir Vincent himself over considerably more than the past 50 years). Although similar to earlier editions, much new material has been incorporated, and more subheadings have increased the accessibility of different subjects in the text. The references have been updated and many new figures added, while the narrative is still admirably readable and comprehensible.

Insect Physiology was originally a pioneer in the Methuen *Monograph* series — little books which were a great boon to earlier generations of student biologists who lacked the huge diversity of modern textbooks. But even if the texts reviewed here are both good in their different ways, do modern students need yet more books, recycled or new? If an established text can be revised adequately, there is good reason to keep it. Wigglesworth's small (but expanding) book probably is most useful in providing an introduction to insect physiology for non-entomological zoologists, or to whet the appetite of entomology students at an early stage of their training. More advanced students will need his *Principles of Insect Physiology* (Chapman & Hall, 7th Edn 1972), or an equivalent expanded treatment.

A new entomology text must provide a fresh look at the subject in order to compete, and Evans has had the advantage of being able to take a contemporary viewpoint throughout. *Insect Biology* would provide an excellent basis for a modern entomology course taught as one of several subjects for a zoology or biology first degree. For a more specialist entomology course, morphological and systematic reinforcement would be necessary, as provided, for instance, by Borror, DeLong and Triplehorn's *An Introduction to the Study of Insects* (Holt, Rinehart & Winston, 5th Edn 1981) or *Imms' General Textbook of Entomology* (Wiley/Chapman & Hall, 10th Edn 1977).

M.E.G. Evans is a Senior Lecturer in Zoology at the University of Manchester.

Stiff Computation

Ed. by Richard C. Aiken

Reviews the art and practice of modelling stiff dynamical systems, covering their occurrence in practice, numerical methods, software packages, theory, and analysis.

0 19 503453 8, £72, c. 400pp., illus., OUP USA, April 1985

Oxford Surveys in Information Technology

Volume One

Ed. by Peter Zorkoczy

A new annual publication – each containing 8 to 10 refereed articles – which aims to summarize important recent developments, identify trends, and stimulate discussion and further work.

0 19 859003 2, £35 (UK), $80 (USA), £42 (elsewhere), 400pp., illus.

Future Computing Systems

NEW JOURNAL

An international journal

Ed. by Brian R. Gaines and Hajime Karatsu

This new journal will contain strategic papers on the development, applications, and impact of future computing systems, providing a forum for the open exchange of ideas.

0266 7207, annual subscription (Vol 1) £50 (UK), $100 (USA), £60 (elsewhere), published quarterly from March 1985

Circle No.06 on Reader Service Card.

SCIENCE PUBLICATIONS

Handbook of the Birds of Europe, the Middle East, and North Africa

The Birds of the Western Palearctic

Volume IV: Terns to Woodpeckers

Ed. by Stanley Cramp and others

The fourth volume of this monumental reference work contains full descriptions of a further 113 species of birds, and is fully illustrated, including specially commissioned colour plates.

0 19 857507 6, £60, 970pp., illus. (inc. maps and 56pp. colour plates), April 1985

Phanerozoic Earth History of Australia

Ed. by J.J. Veevers

A comprehensive and up-to-date account which focuses on morphotectonics, and provides the regional setting for Australia's fossil fuels and other resources.

0 19 854459 6, £55, 436pp., illus., Clarendon Press
Oxford Geological Sciences Series 2

The Jodrell Bank Telescopes

Bernard Lovell

Describes the development of visionary schemes for radio telescopes, and the political and scientific interplay that took place during a critical period in British astronomy between 1960 and 1980.

THE 1984 ABBOTT PRIZE WINNER FOR MEDICAL WRITING...

CELLS AND TISSUES

An Introduction to Histology and Cell Biology

A. W. Rogers

1983, 256pp., $25.00/£13.50 (UK only), ISBN: 0.12.593120.4

Cells and Tissues is a brand new approach to the teaching of histology. It places emphasis throughout on the recognition of commonly occuring structural patterns and relates these to cellular function. Unlike most histology textbooks, it also includes basic aspects of histopathology. The text is supported by over 200 illustrations, of which half are in colour, and includes questions to reinforce important points.

THE PATHOGENESIS OF INFECTIOUS DISEASE

Second Edition

C.A. Mims

1982, 320pp , Cloth. $27.00/£18.00 (UK only), ISBN. 0.12.498254.9
Paper: $13.50/£8.50 (UK only), ISBN· 0.12.498455.X

Professor Mims describes the mechanisms of infection and disease production in a clear and logical manner, dealing, in an integrated way, with all micro-organisms he draws out the factors common to all infectious diseases.

For this second edition, the text and references have been updated, new tables have been added and the text has been expanded giving greater coverage to diarrhoea, sexually transmitted diseases and persistent infections. There is also a brief section on the possible viral aetiology of certain human diseases of unknown origin.

A major new college text

PREHISTORIC EUROPE

T. C. Champion, C. Gamble, S. Shennan and A. Whittle

1984, 376pp., Cloth: $45.00/£28.50 (UK only), ISBN· 0.12.167550 5
Paper. $23.50/£14 50 (UK only), ISBN: 0.12 167552.1

After an introductory chapter on the geographical setting and the development of prehistoric studies in Europe, the rest of the text is divided chronologically into nine chapters. Each one describes, with numerous maps, plans and drawings, the relevant archaeological data, and proceeds to a discussion of the societies they represent. Particular attention is paid to the major themes of recent prehistoric research, especially subsistence economy, trade, settlement, technology and social organisation.

THE PSYCHOLOGY OF HUMAN MOVEMENT

Edited by A. M. Wing and M. M. Smyth

1985, 340pp., Cloth· $55.00/£38.00 (UK only), ISBN: 0.12.653020.3
Paper: $24.50/£16.00 (UK only), ISBN: 0 12 653022.X

This volume deals with psychological approaches to the study of human movement and action and reviews existing knowledge of the representation, planning and control of movement within an information processing framework

This text serves as an indispensable introduction to the complexity and diversity of human movement and will be suitable for undergraduates in psychology, physical education, kinesiology and related disciplines.

BEHAVIOUR

An Introduction to Psychology as a Biological Science

G. Hall

1983, 336pp , Cloth· $35.00/£19 50 (UK only), ISBN. 0.12.319582.9
Paper $16.50/£10.00 (UK only), ISBN· 0.12 319580.2

Behaviour has been written as an introcution to the scientific study of the behaviour of both animals and man. The text concentrates on observable and measurable events and looks for clearly formulated explanations of behaviour that can be tested by experiment or observation It relates the results of such studies to other branches of biology, especially genetics, neurophysiology and evolutionary studies

PLANT-MICROBE INTERACTIONS

Volume 1: Molecular and Genetic Perspectives

Editors: Tsune Kosuge (University of California)
Eugene Nester (University of Washington)

The first in a major new multi volume series which covers the molecular biology and genetics of plant-microbe interactions, describing the latest concepts, research techniques and potential applications in biotechnology.

With particular emphasis on:–

- ★ definitions of concepts and terminology presenting a unified framework used throughout the series
- ★ physiology and genetics of plant-microbe interactions
- ★ modern techniques used in research
- ★ molecular biology of recognition phenomena
- ★ plant responses to the environment
- ★ biological control
- ★ applications of molecular biology to the biotechnology revolution
- ★ techniques and tools for studying both symbiotic and deleterious plant-microbe associations

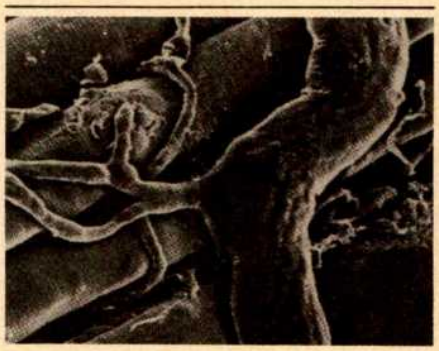
Introducing biology

E.C. Cox & R.M. May



Exploring Biology, 2nd Edn.
By Pamela S. Camp and Karen Arms.
Holt Saunders/Holt, Rinehart & Winston: 1984. Pp.591. £27.95, $32.95.
Bioscope, 2nd Edn.
By Thomas A. Easton and Carl E. Rischer.
Charles E. Merrill: 1984. Pp.719. Hbk £16.95; pbk $19.95.
Biology: The Unity and Diversity of Life, 3rd Edn.
By Cecie Starr and Ralph Taggart.
Wadsworth: 1984. Pp.697. $29.10, £49.60.
Biology: An Introduction.
By Kenneth D. Johnson, David L. Rayle and Hale L. Wedberg.
Benjamin/Cummings: 1984. Pp.615. $28.95, £25.15.

ALL four of these texts are intended for students who will probably take only one biology course and whose teachers are interested in covering the broad range of topics now typically found in standard texts for science majors. Three of them follow what many have come to accept as the preordained little-to-big (molecules to ecology) order of presentation. The exception is Camp and Arms (CA), whose book begins with evolution and ecology, and then proceeds to cells, genetics, plants and animals; this book is essentially a scaled-down version of the same authors' *Biology*, a well-written text for science majors.

With the exception of Easton and Rischer (ER), which has an unfortunate number of errors, these books are scholarly, accurate, up-to-date and well produced — Starr and Taggart (ST) exceptionally so —, including thorough coverage of plant biology, and good discussions of human anatomy and physiology. Although intended for a one-term survey course, they treat the readers seriously, something we found lacking in similar texts when we reviewed this field several years ago. The books have a seriousness of purpose and intellectual rigour that is easily lost when authors try too hard to enliven their subject by making it trendy and "relevant" (and even here there remain lapses from grace, such as the photo in Johnson, Rayle and Wedberg (JRW) captioned "the rock star Johnny Winter is an albino").

ST is an extraordinarily well illustrated book, with figures and photographs that rival those in Curtis's *Biology* for clarity and sheer beauty. The other three books are illustrated well, but none comes close to ST. All the books end each chapter with review questions and a list of suggestions for further reading. These lists are a bit dated, idiosyncratic and exhibit the usual high coefficient of inbreeding with other introductory texts.

The evolution and ecology sections do not strike us as the strongest parts of any of the four books. In this respect, none of them is up to the standards set by Purves and Orians in *Life: The Science of Biology*. There are, however, interesting differences among the four. JRW and ER illustrate speciation with the rather tired example of the beaks of Galapagos finches; CA uses the more compelling example of the Hawaiian honeycreepers; ST also uses the Hawaiian honeycreepers, but with an illustration that is more complete and more beautiful than that of CA. All four books discuss continental drift and its relation to past and present biogeographical patterns, but while the other three show the usual picture of continental drift over the past 200 million years, ST have a new double-page spread correlating the evolution of life with the location of the continents since the late Cambrian (540 million years ago). On the other hand, ST is the only one of the books to perpetuate the appealing but incorrect generalization that roughly 10% of the energy at one trophic level is transferred to the next (it is one of our pet peeves that this "law" is so long in dying). On balance, however, ST seems to have made the greatest efforts to break out from the incestuous patterns — the convergence in use and reuse of familiar examples — that afflict most introductory texts.

Nerve fibres on muscle (x900). The picture is taken from Biology *by Claude Villee* et al., *published by Holt Saunders/Holt, Rinehart & Winston.*

All the books make efforts to incorporate recent advances, going beyond the molecular biology of the gene to the molecular biology of the cell. But the text fully bringing an abstract of Alberts *et al.*'s *Molecular Biology of the Cell* into the introductory classroom remains to be written.

More generally, it seems that if an elementary text is to give some idea of the great diversity of methodology and levels of analysis currently found in the biological sciences, it must sacrifice something in the telling. In the books reviewed here, what is lost is a feeling for the way in which science is done and for the elegance of many experiments. It seems to us that this is inevitable in a non-trivial book for a one-term course, where the emphasis is on scientific content. Whether or not this is how non-science majors should be taught has always been a matter for lively debate, and could well be the subject of a different essay.

None of these books spends more than a sentence or two on creationist theories. Only JRW includes a reference in the index, and the authors briefly and sensibly say that all such conjectures are matters of faith outside the realm of science. This represents a change in college texts over the past several years. Not long ago authors felt compelled to defend Darwinism against attacks from modern proponents of special creation (with Luria, Gould and Singer's *A View of Life* being a high-water mark). Happily, this is no longer so if these texts are at all representative. The poverty of special creation theories as scientific explanation is taken as given.

Broadly speaking, the intrusion of the social and moral concerns of textbook writers into purportedly objective texts must surely date from earliest times. In this respect the books under review also represent a change from recent crops, in that they mainly focus on science, tending to leave out issues that always have seemed to us more properly contained in social science texts. No doubt there will continue to be introductory texts on the market that grip the student with rhetorical pleas for the state of the environment or the brotherhood of man (or siblinghood of persons), but these are not among them. There are lapses, such as ER ending with the time-honoured two views of the future (replete with imaginative illustrations of how "the movement to space could begin with the construction of orbiting space colonies"), but in the main we have factual accounts that balance the many disciplinary calls on the student's attention with the need to remain comprehensive and easy to read.

All in all, we think ST comes out ahead. CA and JRW are both good, with JRW deliberately aiming a bit higher (for example, it gives the mathematics of the Hardy–Weinberg law, while CA does not). ER is pitched a bit lower than the other three, and contains quite a few serious errors and misleading figures: for instance, on page 115 the two polynucleotide chains of the double helix have the same polarity, while the codon table on page 117 is badly scrambled. We like ST best because it is so well illustrated, succinct and marvellously clear. It also manages to cover more ground and to do the best job of the three in the sections on energetics and chemistry, while retaining its comprehensiveness and avoiding excessive length and detail.

Personal preferences notwithstanding, all but ER are good value. This may in part be because the authors have worked closely with their reviewers, as acknowledged in each preface. The majority of the reviewers involved have wide experience teaching the students for whom the books are written. All of us profit from this collaboration. □

Edward C. Cox and Robert M. May are Professors in the Department of Biology at Princeton University.

Vertebrates as a whole

R. McNeill Alexander

Vertebrate Natural History.
By Mary F. Willson.
Holt Saunders/Holt Rinehart & Winston: 1984. Pp.621. £33.95, $37.95.

"NATURAL history" is a term that needs rehabilitation. We tend to use it only to refer to amateur field studies, and in the names of museums, but it is an excellent, succinct description for studies that deal with whole organisms rather than tissues or cells. In *Vertebrate Natural History* Dr Willson uses it very broadly, to refer to subject areas ranging from environmental physiology to sociobiology. She tells us that "for the modern study of natural history, it is inadequate to construct a catalog of cute little tricks employed by organisms".

The book has four parts, which are not well integrated. The first is intended to set the scene, and includes elementary introductions to evolution and allometry, a review of the vertebrates (which is little more than a catalogue of orders, without anatomical detail) and a description of the world's climates and vegetation. The second part is the physiological one, discussing senses, thermo- and osmoregulation, respiration, locomotion and migration, while the third (and shortest) deals with foraging and escape from predators. The final part covers such topics as home range and territory, courtship and mating, life history patterns and parental care.

In this book we are told about a great many aspects of the lives of a great many animals, but there is little cross-reference between one chapter and another and we are not given an integrated impression of the life of any species. The text is superficial, citing a great many investigations but providing little information about any one of them. Explanations are generally facile, without adequate reference to basic principles, and are sometimes misleading. The experimental evidence for statements is seldom given.

There are many fine drawings and photographs of animals mentioned in the text, and the chapters are headed by delightful decorative sketches, but few of the diagrams are original. In some compensation for the vagueness of the text each chapter includes a long list of generally well-chosen references — a remarkable number of the best papers of the 1960s and 1970s are listed, but only a few from the 1980s. □

R. McNeill Alexander is Professor of Zoology at the University of Leeds.

After Darwin

R.J. Berry

Evolution: A Modern Synthesis.
By W.H. Dowdeswell.
Heinemann Educational: 1984. Pp.176. Pbk £6.50.

BIOLOGY first made sense to me when my A-level course reached evolution. The seemingly endless tread-mill of form and function, ethology and ecology, taxonomy and biochemistry suddenly became part of a coherent whole. I was fortunate in my teachers. Many students coming up to university have only a slight or garbled understanding of evolutionary biology; as a result they tend to believe that methodology-driven disciplines such as molecular genetics or behavioural studies are the real keys to biology. Anything that counters this false form of reductionism is good and it is a pleasure to see the appearance of Professor Dowdeswell's latest book.

Thirty years ago, Dowdeswell wrote a book called the *Mechanism of Evolution* in the Heinemann Scholarship Series. This was obviously a success because it went through several editions and reprints. His new book is presumably intended as a replacement. It includes chapters on the origin of life and the palaeontological record, but otherwise has a similar structure to the earlier work. But the new is not simply a rehash of the old: punctuationalism is discussed, as are cladism and creationism (the last not entirely satisfactorily; but it is refreshing to find a fundamentalist correctly defined as one who adheres to the fundamentals of Christian faith), and odd snippets of information crop up which identify the book as written by someone who knows the subject rather than an intelligent hack who simply recycles existing texts. (For example, sickle cell haemoglobin homozygotes are conventially regarded as having zero fitness, but Dowdeswell describes a Saudi population where fetal haemoglobin persists into adult life and increases the fitness of sickle homozygotes apparently to unity; and the influence of plant density on the frequency of primrose homostyles is described, taking the standard story of their maintenance away from mere speculation about the effects of inbreeding.)

Evolution is a text for sixth formers and for those undergraduates arriving at university with only a tenuous grasp of the subject. It is admirably designed for that readership, as would be expected from a teacher of Dowdeswell's experience. My only grouse is that it may be too placid: will it excite current generations of A-level candidates? I don't know; I can only hope.

R.J. Berry is Professor of Genetics at University College London.

An idea of primates

Michael Simpson

Primate Behaviour and Social Ecology.
By Hilary O. Box.
Chapman & Hall/Methuen: 1984. Pp.283. £10.95, $22.95.

THOSE who enjoy working with and reading about primates for their intrinsic interest will welcome this book as a rich vein of information and reference. Here is an uncontroversial source to complement those primate behaviour courses which concentrate upon just a few strong ideas, illustrated with a handful of examples, described in depth. It is indeed useful to have a psychologist's synthesis of approaches to "intelligent" responses to changes within social and physical environments, evident in the sections "Responsiveness and Life Strategies", "Self-awareness", "Piagetian Techniques", "The Use of Tools" and "The Question of Culture". Other kinds of material, such as Packer's study of male transfer in baboons, are well summarized for teaching purposes.

However, two *caveats* should be made in reponse to the book's advertisement of itself as a text for students. First, strong theoretical lines are not pursued. It could be argued that in so far as the study of primate behaviour is in a "fact-gathering hypothesis-testing" phase, this book's unfocused Aristotelian approach is appropriate, and most of the current ideas available (including so-called sociobiological ones) cannot do justice to the complex data. But a particular viewpoint can also sharpen our focus on factual material, and there is already a harvest of particular facts whose quiddity cries out for theoretical support. Why, for example, should chimpanzees and bonnet macaques be almost the only multi-male primate groups in which males groom each other extensively? Why do the daughters of so many macaque families rank socially in inverse order of their ages? Theories answering such questions could have much to say about social competition and co-operation.

My second reservation is that students will not always find that closer reading clarifies difficult passages. For instance, gender ratio adjustments in Japanese macaques (p.120) and vervet monkeys (p.233) are mentioned, but the directions of such adjustments cannot be found in the text. Fig.6.9 lacks a code for its letter symbols which would let it show "the situation clearly" (p.241). In some passages (for example p.43) the author is worsted in "the intolerable wrestle with words and meanings". □

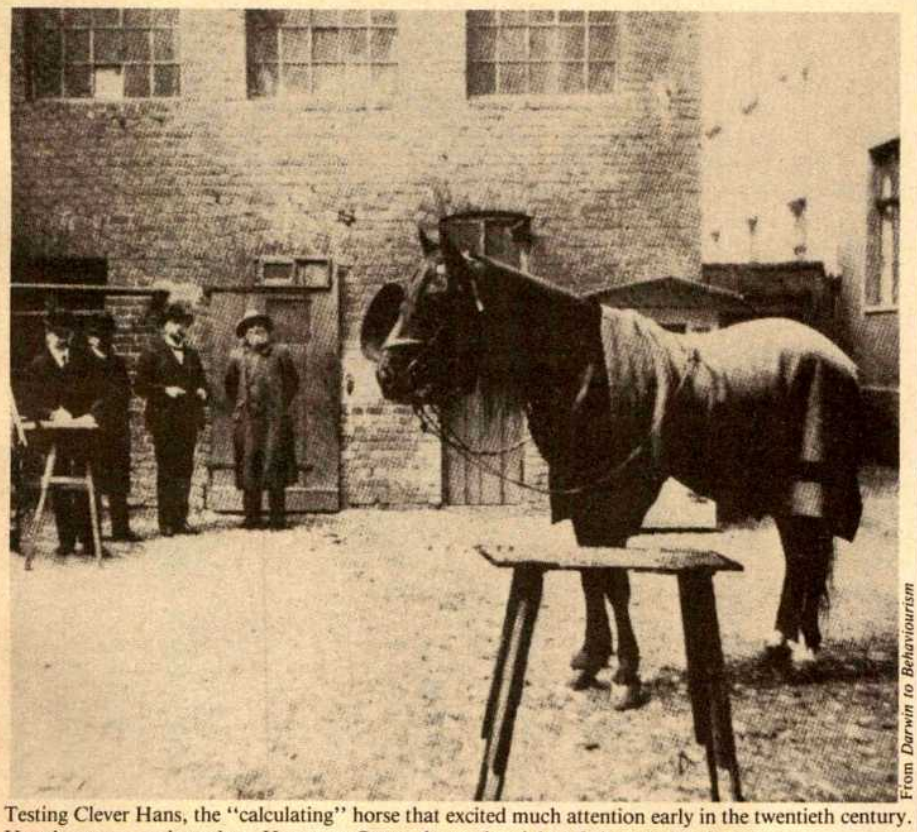
Michael Simpson is in the Medical Research Council's Unit on the Development and Integration of Behaviour at the University of Cambridge.

Telling tales

Geoffrey Hall

From Darwin to Behaviourism: Psychology and the Minds of Animals.
By Robert Boakes.
Cambridge University Press: 1984. Pp.279. Hbk £35, $69.50; pbk £15, $19.95.

DISCUSSING the implications of his theory, Darwin wrote in the *Origin of Species* that "psychology will be based on a new foundation, that of the necessary acquirement of each mental power and capacity by gradation. Light will be thrown on the origin of man and his history". But the facts of psychology were to prove troublesome to Darwinian theory as he himself acknowledged in the *Descent of Man*: "the high standard of our intellectual powers and moral disposition is the greatest difficulty which presents itself, after we have been driven to this conclusion on the origin of man".



The problem for supporters of the "continuity hypothesis" was to find evidence for the existence of mental powers in non-human animals and this Darwin and his successors (notably G.J. Romanes and C.L. Morgan) set out to unearth. Their work forms one of the foundation stones of modern behavioural psychology and constitutes one of the major themes of Boakes' excellent book.

An earlier view of the nature of animal behaviour has its origins in Descartes' notion of them as reflex automata. The second theme of the book is found in Boakes' discussion of the concept of the reflex as the mechanism of animal behaviour from its Cartesian origins, through la Mettrie, Hartley and the work of nineteenth-century German physiologists, to that of Pavlov and associates.

The two themes come together in the final third of the book, when we move to the early twentieth century and the scene of intellectual activity switches, for the most part, from the Old World to the New. In the United States we see the creation of an explicit behaviourism, a view of psychology which, to put it crudely, accepted a reflex account of animal behaviour but which avoided any conflict with evolutionary theory by its willingness to apply (or try to apply) the same account to human behaviour. Boakes, of course, does not put it crudely and his thorough discussion of behaviourism and its implications should help to counteract the simplistic and condescending descriptions to be found in so many textbooks.

Altogether this book is a fine achievement. There is no doubting the depth of scholarship but this is also a good story, well told, which should appeal to psychologists and philosophers not primarily interested in the history of their subjects. And everyone will obtain pleasure and instruction from looking at the illustrations, many of them from private sources and quite new to me, the discovery of which must have been a formidable undertaking in itself. □

Geoffrey Hall is Senior Lecturer in Psychology at the University of York.

From *Darwin to Behaviourism*

Testing Clever Hans, the "calculating" horse that excited much attention early in the twentieth century. Hans's owner and teacher, Herr von Osten, is on the right of the group of men.

Psychometrics at the trot

Steve Blinkhorn

Psychological Testing.
By John R. Graham and Roy S. Lilly.
Prentice-Hall: 1984. Pp.433. $39.10, £35.60.

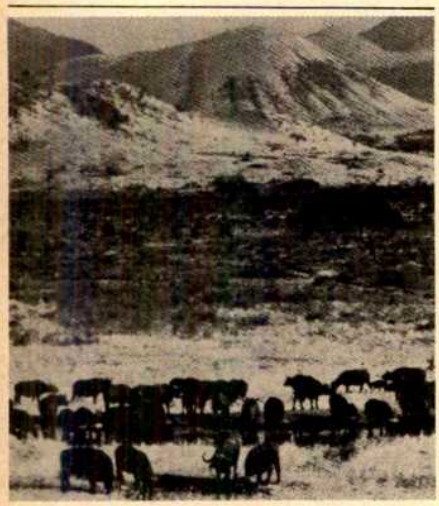
ON FIRST acquaintance with psychological testing there is a constant demand from students for emphasis on details of published tests and their application. On the other hand lecturers may very properly feel that a sound grasp of psychometric methodology is of more value in getting to grips with the often difficult and tendentious issues associated with the use of tests.

Graham and Lilly have resolved this tension in favour of the demand from below. After a quick, elegant canter round the basic statistical and mathematical concepts, the bulk of this book is given over to description and evaluation of published tests. The student is introduced to a range of issues via a discussion of particular tests, and appropriate primary sources are referenced. Concluding chapters present an overview of assessment as a process, and of controversial issues in the use of tests.

Within its self-imposed limits the book is admirably written, providing a smooth, well thought out account of most of the topics one would wish to include in an introductory course. This is a fundamental failing. There is no challenge left when every dilemma is polled, every contentious issue sanitized and a range of sound, sane opinion presented neatly gift-wrapped as if ready for instant regurgitation in a multiple-choice quiz.

This is not merely reviewer's dyspepsia: textbooks of this kind, for all their merits as digests, encourage amongst students the attitude that certain matters of opinion or judgement are matters of settled fact. A quick glide through classical test theory and reliability has been "done": now on to the serious business of discussing the value of ink-blots. As a result we have the all too common treatment of tests (referred to airily by acronym — a sure sign of the initiate) as the subject matter of psychometrics. This is the very opposite of the independent critical outlook one would wish to engender in those who may come to make use of tests. They may forget that those tested are people, and that test data do not have an independent existence apart from those people.

Non-American readers will find the list of tests considered parochial and occasionally out of date. They will also find the price beyond what it is reasonable to ask a student to pay. □



Steve Blinkhorn is Director of the Psychometric Research Unit and Senior Lecturer in Psychology at Hatfield Polytechnic, Hertfordshire.

Different behaviour

Richard J. Cowie

Animal Behavior: An Evolutionary Approach, 3rd Edn.
By John Alcock.
Sinauer/Blackwell Scientific: 1984. Pp.596. $25, £19.80.
Biology of Animal Behavior.
By James W. Grier.
Times Mirror/Mosby/Blackwell Scientific: 1984. Pp.693. $28.95, £32.50.

WITH new textbooks on animal behaviour appearing every few months, it is an achievement for any one of them to reach a second edition. John Alcock has gone one better, and his well established textbook is now appearing for the third time. What is more, revision of the previous edition has not just been cosmetic. The book has been largely rewritten and the material has been reorganized into a more logical sequence. John Alcock is a good writer, and like its predecessors this edition is a joy to read. It is also well produced, and the layout, figures, photographs and binding are superb. A nice addition is a series of colour photographs on the inside of the covers.

Buffalo at home on the range in the Tsavo National Park, Kenya. The picture is reproduced from Ecology of Natural Resources *by François Ramade, published by Wiley.*

Major changes to the content are the inclusion of a chapter on the development of behaviour and expansion of the section on sexual selection and mating systems. Both are improvements, but the book still has weaknesses which mar its usefulness as a general introductory text. These weaknesses stem from Alcock's interest in the evolution or function of behaviour, at the expense of a causal approach. For example, there is no mention in the index of such key concepts as motivation, ritualization or habituation, and the important topic of classical learning theory is dealt with in two short paragraphs under the sub-heading of plastic developmental systems.

Besides these obvious omissions there are two further points which concern me. The first is Alcock's tendency to invent explanations in terms of evolutionary advantage for almost every behaviour mentioned, including many aspects of human behaviour. Whilst I recognize the temptation to do this, there is a danger that naive readers may accept these speculations as established fact. My second worry is Alcock's failure to present any of the more mathematical models which have been successfully used to predict how animals do behave. This is particularly true for the many optimality models, which the author praises for producing quantitative predictions (p.200) but fails to describe in any detail. However, despite these weaknesses — or perhaps because of them — I am sure the book will remain popular with many students.

Whereas Alcock's book is restricted in outlook but well organized and enjoyable to read, Grier's book is just the opposite. It is one of the most comprehensive textbooks on animal behaviour that I have seen, but the sheer volume of information and the order in which it is presented leaves one a little breathless and bemused. That is not to say that the book is badly written and in general Grier's summary of each topic is good. He tackles many controversial subjects, such as the sociobiology debate, in an informed and balanced way.

Besides covering the more usual subjects, the author provides a crash course in both molecular and Mendelian genetics, an interesting historical perspective to the study of behaviour, and chapters on the observation and measurement of behaviour, abnormal behaviour, and applied behaviour, although these last two chapters are too simplistic to be of much use. The book is well laid out with many photographs and figures, the latter being generally well explained with lengthy captions, although some are confusing (for example those on p.42 and 43). There are numerous small details in which I would disagree with Grier, but overall I was very impressed with his encyclopaedic treatment of the subject and his evident grasp of many diverse areas of zoology.

If I were to choose one of these books to sit down and read for my own enjoyment, it would be Alcock's. But if I had to recommend one as a textbook to students it would be Grier's. □

Anything is possible

P.N.R. Usherwood

Neuroethology.
By Jeffrey M. Camhi.
Sinauer/Blackwell Scientific: 1984. Pp.416. $30, £24.

THE TASK of keeping abreast of developments in the biological sciences grows daily, even within the strict confines of one's own specialism. It was with some misgivings, therefore, that I approached this review, especially since my only credential was a brief love affair with invertebrate neuroethology in the late 1960s. However, my fears were unfounded since here is a book which is both highly informative and thought-provoking. Its aim is to introduce readers to the major concepts and research strategies which characterize neuroethology, a field of biology which continues to struggle for identity in an uncompromisingly compartmentalized world. Neuroethology remains an essentially schizophrenic experience, spanning neurobiology and ethology and making brave efforts to marry their languages and dogmas, but regrettably achieving little more, so far, than the connection of their fringes.

Neuroethology is essentially a book of two parts, one an introduction to the field, the other an account of nervous integration and behaviour. It is best when the author draws from personal research experience, one highlight being his description of cockroach escape behaviour and its neurobiological basis. My only criticism is that the emphasis is strongly anatomical and phenomenological with inadequate attention given to the advances in molecular neurobiology which have illuminated the past decade. There are good chapters on the visual and auditory worlds of animals, which contain essential background on physical factors in the environment, and useful accounts of sensory processing and motor control. Each chapter is concluded by questions for discussion and a good list of articles for further reading.

The author finishes, quite rightly, by marvelling at the complexity which characterizes the nervous systems of even "simple" animals and suggests, for example, that even after examining the circuit diagram of neurones in the leech we are left wondering how it works. This injection of mystery hints at a latent vitalism which denies the essentially mechanistic nature of neuroethology. He also lists six principles of neuroethology which he suggests have already been established and then argues that these are probably not global but restrictive and conditional. This lack of unifying principles is understandable in a fledgling science but it is unlikely to encourage the meek to enter the field. But Camhi has rekindled my interest in an old flame and all biologists with an interest in animal behaviour and nervous systems, simple and complex, will find his book well worth reading. □

P.N.R. Usherwood is Professor of Zoology at the University of Nottingham.

Announcing... a major new text in medical microbiology

MEDICAL MICROBIOLOGY

An Introduction to Infectious Diseases

Editor: John C. Sherris,
School of Medicine, University of Washington, Seattle, Washington

Coauthors: Kenneth J. Ryan, *College of Medicine, University of Arizona, Tucson, Arizona;* C. George Ray, *College of Medicine, University of Arizona, Tucson, Arizona;* James J. Plorde, *School of Medicine, University of Washington; Seattle, Washington;* Lawrence Corey, *School of Medicine, University of Washington, Seattle, Washington; and* John Spizizen, *College of Medicine, University of Arizona, Tucson, Arizona. (With a contribution by Murray R. Robinovitch, School of Dentistry, University of Washington)*

This outstanding text, developed from the authors' extensive experience in teaching medical microbiology and in its applications, effectively correlates basic microbiology to the disease states encountered in patient care. Throughout, particular attention is given to an even and consistent exposition of the major characteristics of etiologic agents, pathogenic processes, and to the epidemiology and the basis of therapy of infectious diseases. The information is imparted in a manageable, integrated style that affords stimulating reading and clearly directs the reader to essential concepts. The presentation assumes some previous or parallel study of immunology.

Rigorously edited throughout to ensure continuity, ***Medical Microbiology*** includes these helpful features.

- Marginal notes to help students pinpoint essential concepts
- Tables and appendices for further explanation and review
- 29 color plates and photographs
- More than 150 black-and-white illustrations
- Marginal illustrations of microbial morphology
- A glossary of clinical and technical terms
- References to especially useful monographs, reviews, and papers

In the face of massive additions to knowledge of basic biological mechanisms, an increased number of recognized disease states, and new biomedical procedures, this text provides an up-to-date, carefully selected, and manageable account of microbiology directed at those who will be responsible for the diagnosis and care of patients

Fresh selection

T.R. Birkhead

Behavioural Ecology: An Evolutionary Approach, 2nd Edn.
Edited by J.R. Krebs and N.B. Davies.
Blackwell Scientific/Sinauer: 1984. Pp.493. Hbk £25, $42; pbk £13.80, $25.

BEHAVIOURAL ecology has come a long way since the first edition of this book appeared six years ago, and is still moving fast. Some second editions are gentle updates, or ever so subtly improved versions of the first, but this is virtually a new book. There are very few chapters unchanged from the 1978 edition, the only exception being Maynard Smith's sex. Several of the chapter titles are the same as previously but often with new authors and certainly with a great deal of new information. As before the emphasis is on theory and the book is aimed at researchers and dedicated final-year students.

Behavioural ecology was born out of the cross-fertilization of ideas from several disciplines and it is exciting to find that the scope of *Behavioural Ecology* has expanded to include two additional topics, learning (Chapter 7 by Shettleworth) and plants (Chapter 14 by Charnov). While plants clearly don't behave as animals do, behavioural ecology theory has much to offer botanists. Considering the rich rewards that so many zoologists have gained from the use of selection thinking, it is somewhat surprising that botanists have lagged behind. Charnov's chapter deals with sex choice, breeding systems and the conflicting interests of males and females. These are not the only areas of common ground for zoologists and botanists; others (at Sheffield and the University of East Anglia) are already looking at the foraging behaviour of plants!

In Chapter 12 Emlen updates his review of cooperative breeding — clearly a necessity if the number of birds known to breed in this way is any measure of this subject's interest. In the first edition Emlen noted that there were 150 known cooperatively breeding birds: the figure is now 300! The diversity of such breeding systems has also increased but at a much faster rate than our understanding of how they evolved. Cases in which close kin act as helpers are relatively easily explained, but why unrelated individuals should help is more problematical. Emlen discusses reciprocity, but another possibility, not yet fully explored, is that helpers mate with breeding females and actually help to rear their own young.

All in all this is an excellent text. It is well produced, clearly written and provides plenty to think about. □

Wholesome ecology

Robert H. Smith

Ecology: Principles and Practice.
By W.H. Dowdeswell.
Heinemann Educational: 1984. Pp.312. Pbk £7.50.
Concepts of Ecology, 3rd Edn.
By Edward J. Kormondy.
Prentice-Hall: 1984. Pp.298. Hbk $29.65, £27; pbk $22.90, £20.85.
Principles of Ecology.
By R.J. Putman and S.D. Wratten.
University of California Press/Croom Helm: 1984. Pp.388. Hbk $22.50, £22.50; pbk $9.95, £9.95.

FEW textbooks that attempt to encompass the whole of ecology have received widespread acclaim. Odum's *Fundamentals of Ecology* (Saunders, 1953), Krebs' *Ecology* (Harper & Row, 1972) and Ricklefs' *Ecology* (Nelson, 1973) are the three which have been most often adopted as set texts, and all have run to second and third editions. Recently, the trend among publishers has been to launch series of smaller books, each dealing with a specialized aspect of ecology. However, many lecturers like to recommend a single book for purchase by first-year students which will also provide an introduction to later, more specialized courses.

Of the three books reviewed here, two are aimed firmly at the undergraduate market while Dowdeswell's *Ecology* is intended mainly for sixth formers and first-year university students. Dowdeswell's book is quite different from the other two and I shall consider it first. Dowdeswell provides a very basic introduction to ecological principles, going from physical factors through population dynamics to communities and ecosystems in less than 60 pages. No topic is considered in depth, nor is it intended to be. The book is written as extended notes with keywords highlighted in bold type and is clearly aimed at British, pre-university examination syllabuses. The second quarter of the book is about collecting and analysing data, and those involved in setting up simple field exercises for students may appreciate some of the practical tips. I do, however, have severe worries about the oversimplified treatment of statistics; for example, the statement "in order to avoid sampling error, the whole population should be collected but this is obviously impossible" does nothing to help the student struggling with the concept of the infinite population from which a sample is taken. The rest of the book runs through six groups of ecological communities and concludes with the obligatory chapter on ecology and man. I do not imagine that the level of description will be adequate for any biology degree courses, but the book is nicely produced and will probably do well in the pre-university market at which it is aimed.

Kormondy's *Concepts of Ecology* is a middle-aged standard, first published in 1969 and possibly running to fat in an expanded third edition. My personal view is that his treatment of ecology is unexciting in both content and presentation. Most of the references are to books or general articles in *Science* and *Scientific American*; though adequate for first- and second-year undergraduate courses, final-year students need something more demanding. Just as Dowdeswell's book is parochially British, Kormondy's is parochially American and I could not find a single reference to European ecological journals: have *Oikos*, *Oecologia*, the journals of the British Ecological Society or *Nature* never published anything worth mentioning? Kormondy's approach is the standard one, dealing first with energy flow in ecosystems and biogeochemical cycles, then with population ecology and community organization, finishing off with human ecology.

Principles of Ecology by Putman and Wratten is the largest and most comprehensive of the three, with over 500 references, mostly to original papers. The order in which material is presented is the first feature that strikes the reader; after the usual introductory chapter on tolerance to abiotic factors and physiological and behavioural homeostasis, the authors launch straight into the ecological community as the unit of study. In some ways this unusual approach is a good one, since energetics and nutrient cycling are dealt with in an integrated way with species-abundance relations, community dynamics and succession. However, I did find that the links between different topics in the first four chapters are not made all that clear, and I reckon that students will have some difficulty in following the chapter on the niche without first thinking about intra- and interspecific competition (which come later). It is in the chapter on interspecific competition that the deficiencies of treating species interactions before single-species populations become most apparent. In order to develop a Lotka-Volterra model, exponential and logistic population growth models are skimmed through in a few lines, and the presentation of the conditions for coexistence is terrible.

Putman and Wratten place their chapter on population structure and analysis centrally — which of course means that the central concepts presented there are rather lost. The expanded repetition of exponential and logistic population models is again badly presented and likely to confirm the average biology undergraduate's prejudices about mathematical representation. A brief consideration of life tables leads into key factor analysis and the use of k-values but, like many authors, Putman and Wratten do not emphasize the direct link between the methods of analysis and implicitly assumed population models. Perhaps I am

being too critical of their coverage of topics with which I am most familiar, but I believe that it is extremely important to present quantitative concepts as clearly as possible without oversimplifying.

My final comment is about the way that evolutionary questions are dealt with in ecology textbooks. Kormondy hardly considers such questions, though he mentions natural selection when discussing biotic potential — and in my opinion gets it badly wrong when he says "To remain in the game, it appears that for a decreased value of r compensations have been achieved by natural selection in increased generation time". Putman and Wratten have chapters on evolution and adaptation, and coevolution. Again, I could raise objections to much of what is said, but the authors are to be commended for stressing the relationship between ecology and evolution — albeit rather late in the book. Theories of evolution and ecology have not been well fitted together in the past, but things look more promising now. In particular, I feel that life history theory forms an important link, and behavioural ecologists are at last considering the ecological consequences of their theories and tests of optimality. These are two of the most exciting developments in ecology in the 1980s, and one hopes it won't be too long before they reach the textbooks. □

Living in salt waters

Michael M. Mullin

Biological Oceanographic Processes, 3rd Edn.
By T.R. Parsons, M. Takahashi and B. Hargrave.
Pergamon: 1984. Pp.330. Hbk £22, $40; pbk £10.95, $19.75.
Marine Ecological Processes.
By Ivan Valiela.
Springer-Verlag:1984. Pp.546. DM 118, $44.
Basic Marine Biology.
By A.A. Fincham.
Cambridge University Press: 1984. Pp.157. Hbk £20, $36; pbk £7.95, $14.95.
Marine Biology.
By H.V. Thurman and H.H. Webber.
Charles E. Merrill: 1984. Pp.446. $28.95, £14.95.

ONE criterion in assessing the usefulness of new textbooks on marine ecology is whether recent findings, such as the hydrothermal vent communities, or renascent subjects, such as bacterial and protozoan ecology, are treated but also kept in perspective. Also important is whether the book covers other aspects of contemporary marine science — plate tectonics, mesoscale oceanographic fronts and eddies, interannual variability in oceanic climate and so on — in explaining marine biological phenomena. Finally, issues in general ecology, such as the role of disturbance in structuring non-equilibrium communities or food-limitation versus predator-limitation of population sizes, should be surveyed.

In the most strictly oceanographical book of the four reviewed here, Parsons and colleagues retain the "food web" emphasis of their earlier editions. They explicitly ignore intertidal and coral communities (and hydrothermal vents), and do not discuss sampling equipment. About 30% of the references are new and there are some new illustrations, for example of plankton at fronts, planktonic life cycles, isotopic ratios and how these can reveal food sources, and effects of pollution. To my mind, justice is not done to some new work (for example microbial heterotrophy), and the chapters on plankton seem to have been less thoroughly revised than the chapter on benthos. The concluding chapter on pollution and fisheries has been enlarged the most, and contains cogent accounts of why these problems continue to defy easy solution.

In its detail, emphasis on processes and citation of original literature this is a text for quite advanced students. As such, comments on the mismatches between what we can (and do) measure and what we need to measure would strengthen the early chapters. The authors do not shun algebraic equations, though the level of mathematical treatment of different subjects is uneven. In the next edition, the authors could further emphasize processes by combining related subjects, such as secondary production or bacterial chemosynthesis, for plankton and benthos.

In his book, Ivan Valiela has done this admirably; each chapter presents the conceptual basis of an ecological process and examples from the water column, the benthos (including intertidal and estuarine habitats) or fresh water. Valiela summarizes physical or geological aspects only as related to specific ecological processes; his emphasis is very much on biotic interactions, and he discusses fisheries in this context rather than separately. He cites very recent studies, dares to speculate occasionally, and frequently indicates the observational and experimental evidence behind a generalization. The book is not easy reading, and supplementation by material from oceanographical sources may be desirable, but advanced students will find here a stimulating summary of modern marine ecology. I wished only for a fuller account of interannual variability in oceanic circulation and its effects on distributions.

Fincham writes for a general audience, and understandably devotes much of his book to marginal areas — the intertidal zone and estuaries — on which many human activities directly impinge and which are accessible to classes. There are useful diagrams of physical processes affecting biology (even sea-floor spreading) and many drawings of organisms, though several illustrations are superfluous. The focus is upon organisms and their interactions with the physical environment; more abstract concepts of food webs and communities are briefly treated as qualitative and static generalizations. There is the expected account of fisheries, but also unusual chapters on behaviour and biogeography which introduce such recent evolutionary terms as reproductive strategies, kin selection and altruism (though I believe these concepts are less representative of marine ecology than is, for example, the cycling of nutrients). There are good drawings and descriptions of equipment from a historical perspective, but Fincham does not elaborate upon the sources and strengths of evidence. The discussion of the intertidal zone, for instance, could easily have illustrated the value of manipulation by removal, transplantation or caging of organisms.

The diversity of illustration, ranging from sketches so crude as to be useless to a section of colour photographs, impressed me in the massive text by Thurman and Webber. There are also "study aids" — end-of-chapter exercises and appendixes, the latter including the metric system, taxonomy, a glossary *and* a dictionary of prefixes and suffixes. Over a hundred pages are devoted to organisms *per se*, and many aspects of the environment are

treated in similar detail, all without the mixed blessing of citations from the original literature. The authors introduce some very recent work, biological and otherwise, and also give a taste of how contemporary oceanography is done. Insertion of brief essays on special topics, including a couple of speculative interviews, varies the pace for the reader.

I continue to prefer the drier, academic style of Parsons *et al.* and Valiela. Students who are mature enough to appreciate the enormous wealth of information presented by Thurman and Webber should also be curious enough to check original sources for points of evidence occasionally, and should be willing to cope with concepts in a mathematical as well as a descriptive form. □

Ecological thoughts

John Lawton

Community Structure and the Niche.
By Paul S. Giller.
Chapman & Hall/Methuen: 1984. Pp.176. Pbk £5.95, $11.95.
Predation.
By Robert H. Taylor.
Chapman & Hall/Methuen: 1984. Pp.166. Hbk £17.50, $39.95; pbk £8.95, $17.95.

PREDATION and interspecific competition are key ecological processes, although there is currently profound disagreement about their relative importance in structuring communities. Both phenomena have also spawned a diffuse and specialized literature that students and teachers alike find hard to break into. There is therefore considerable scope for good, simple introductory texts on both topics.

Giller's book has as its main theme the organization of communities, in particular the processes that control the numbers and relative abundances of species. It ranges widely to include discussions on predation, species–area relationships and food webs, although the dominant theme throughout is the concept of the ecological niche, as conceived by G.E. Hutchinson, nurtured by R.H. MacArthur and subsequently embraced by a whole generation of ecologists. In contrast, Taylor focuses on two- or three-species interactions, with a clear emphasis on mathematical rigour, testable hypotheses and the continual interplay between theory and experiment. Only in the last, short, chapter does he look at predation in communities, drawing the conclusion that "students of whole communities will need to be satisfied with a descriptive approach to static . . . patterns" — more or less what we find in Giller's book.

In general terms, therefore, the books make an interesting pair, with the potential at least to introduce students to a wide range of ecological problems and ways of thinking. Both are written for second- or third-year undergraduates, and postgraduates, with Giller's perhaps more accessible to novices and Taylor's decidedly more interesting for research ecologists of any age.

Specific details aside, I have some personal doubts about whether *Community Structure and the Niche* truly catches the spirit of its subject matter in the mid-1980s. Giller undoubtedly tries to explain controversies, and to draw attention to the uncertainties, doubts and problems that abound in this area of ecology. But he still left me with the impression that in spirit and philosophy the book could have been written in 1975. Moreover, I frequently found myself disagreeing with his main conclusions and interpretations, whilst in certain places crucial literature was ignored. A number of other things about the book also reduce its value as a teaching text. The 326 references appear in citation order (as in a letter to *Nature*), making it very difficult to follow the work of particular authors. More seriously, I frequently felt that the text was so packed with hurried references that many ideas would be unintelligible to all but the initiated. This fear was confirmed when I tested several sections on a brighter than average tutorial group. They found them cryptic and baffling. A slightly longer text, with less frenzied, fleeting allusions to everything that might be relevant would undoubtedly have made a better book.

No such criticisms can be levelled at Taylor. He explains theory and experiment with a lucid, direct style. Predator–prey interactions, ranging from protozoa, through insects, to birds and mammals, are mainly described using differential equations, but not in a way that should put off students — the mathematics is not very hard, and is made more palatable by plenty of graphical interpretations. I was particularly impressed by Taylor's careful discussions of why ecologists find it useful to construct mathematical models, and by his repeated attempts to highlight problems and difficulties, both in the construction of tractable models and in their empirical tests. In short, *Predation* should instil in young ecologists a way of thinking about problems that will be valuable whatever ecological processes they go on to study.

Predation may or may not be more important than competition as a force structuring ecological communities. Perhaps the next generation of ecologists will find such comparisons, and questions of relative importance, boring. But while we are training them to decide, I have no doubt that *Predation* provides more insights and a better foundation than *Community Structure and the Niche.* □

Southern histories

Barry Cox

Vertebrate Zoogeography and Evolution in Australasia.
Edited by Michael Archer and Georgina Clayton.
Hesperian Press, 65 Oats Street, Carlisle, 6101 Western Australia: 1984. Pp.1,202. A$55. Post and packing A$10 inside Australia, A$14 overseas.

THIS is not so much a coffee-table book as a coffee-table in itself (area 650 cm^2, weight 3kg). Sixty authors have contributed 80 papers; most are concerned with Australia, but 13 deal with New Guinea, New Zealand and Lord Howe Island.

For Australians interested in biogeography and evolution, the trouble is that most books on these subjects treat Australian examples as a sort of awkward appendage, tacked on as a divine afterthought to the rest of Creation — a sabbatical daydream in which evolutionary fagends (for example monotremes) or pseudo-mediaeval beasts (kangaroos, wombats, moas and so on) were conjured up, their bizarreness emphasizing the sturdy normality of Northern Hemisphere animals, and their almost total lack of an evolutionary history teasing the poor palaeontologist. Australian students, in particular, have long needed a book centred on their part of the world. Well, here it is.

The first 13 contributions provide the background information relevant to Australasia in such topics as plate tectonics and palaeogeography, ecological zoogeography, the history of the climate and flora of Australia, vicariance and dispersal biogeography, and systematics. Each of the following sections on fish, amphibians, reptiles, birds and mammals commences with an account of the general evolutionary history of the group and ends with a checklist of the Australian representatives. The remaining contributions (a few being reprints of original research papers) deal with aspects of the zoogeography, evolution, ecology or discovery of Australian members of the group, or with the effects of man upon them. The book contains many figures and half-tone illustrations, and a few colour plates. The text is sometimes lighthearted in tone, and is also enlivened by occasional cartoons.

Though the quality and depth is inevitably a little patchy, this is in general an excellent student textbook. Even adding A$14 for postage and packing, it still works out at about 0.04p per page. So students should buy it now, use it as a reference book until it's out of date — and then have a ready-made doorstop. □

Barry Cox is Head of the Department of Zoology at King's College, University of London.

Biotas in space and time

Carolyn M. Harrison

Biogeography: An Ecological and Evolutionary Approach, 4th Edn.
By C.B. Cox and P.D. Moore.
Blackwell Scientific: 1985. Pp.236. Hbk $19; pbk £9.80.
Themes in Biogeography.
Edited by J.A. Taylor.
Croom Helm: 1984. Pp.404. Hbk £25; pbk £12.95.

WHEN the first edition of Cox, Healey and Moore appeared in 1973, it quickly established itself as a popular text and successive editions have served to reinforce its appeal. In this new edition, the authors have retained the essential structure of the immediate predecessor, and have expanded two chapters to discuss more fully how the major patterns of biota emerged in the distant and recent past. They do this with the distinctive blend of description and analysis adopted in earlier editions and the student is left in no doubt about the difficulties of reconstructing palaeoenvironments and their associated biotas.

The evident emphasis on analysis of the spatial response of biota to plate-tectonic movement and climatic change will be welcomed by many, but it has been achieved at the expense of any real discussion of how plants and animals adapt to their changing environments. In earlier editions, a chapter on natural selection, inbreeding and adaptation formed an important functional link between the evolutionary and ecological perspectives that the book seeks to forge. The omission of these topics in the new edition is not unexpected, given the complexity of evolutionary and ecological genetics; nevertheless their absence merely serves to reinforce a retreat from the stress on ecology that can be detected in the earlier editions. The task of preserving a balance among differing views of biogeography is a challenging one and it is easy to be dismissive of the value of ecological studies for students who are interested in the history of distinctive floras and faunas. But, for those large numbers of biogeographers who are intrigued by the impact of human activities on the distribution and survival of biota when seen as resources and cultural symbols, an ecological perspective is just as fundamental as an evolutionary one. As a result students in biology and geology departments will be better served by this new edition than will their fellows in departments of geography and environmental studies.

The tensions provoked by the position of biogeography at the meeting point of several disciplines is nicely revealed through the 11 essays edited by J.A. Taylor. This volume is addressed to the advanced student and aims to provide a representative selection of traditional and emergent themes in biogeography, as seen by British researchers. The result is something of a potpourri. In these essays biogeography emerges as a multifaceted subject and as one to be approached in a variety of ways and with a range of analytical tools. Each essay stands on its own; most are scholarly, informative and up to date; some are idiosyncratic and a few are dull. Of more concern than the disparate nature of the assembled topics, however, is that here an opportunity has been missed. Many researchers will be disappointed to find that the chance to raise the level of debate about research priorities was not grasped more fully. Moreover, aspiring researchers will find little to help them decide which of the several methodologies or techniques available are the most appropriate for tackling particular problems. This is not to belittle any one of the individual contributions to the volume, but rather to point to the benefits that a more obvious and focused discussion of research developments would have brought.

Biogeography has experienced something of a renaissance in recent years and some of its popularity can be attributed to the well-deserved success of books such as Cox and Moore. I cannot help feeling however, that students who are inspired early on in their careers by these authors, will not find their enthusiasm fanned equally by a reading of Taylor's volume. And that is a pity. □

Carolyn M. Harrison is a Lecturer in the Department of Geography at University College London.

Change in population

Michael B. Usher

Population Biology: The Coevolution of Population Dynamics and Behavior.
By John Merritt Emlen.
Macmillan, New York/Collier Macmillan, London: 1984.*
Pp.547. £31.50.

HOW would most population biologists answer the question "how much mathematics should a student know?". Dr Emlen leaves the reader in no doubt since his book commences with a mathematical introduction, the "tools of the trade". The tools largely consist of matrix algebra, with, in addition, complex roots, variance and covariance, partial derivatives and the Taylor expansion. After this explanatory introduction it is odd that these mathematical concepts, especially matrices, are not made more of in the subsequent text.

Most of the topics that one would associate with a population dynamics textbook are covered — populations with and without age structure, predator–prey interactions, competition and multi-species interactions — though it is, perhaps, surprising that parasitoids and mutualism are hardly mentioned. The book starts to diverge from the usual text when a strong genetical flavour is introduced in chapters that look at the genetic structure of populations and analyse models developed to deal with population parameters, either at a single locus or at multiple loci. Fitness is considered, largely by posing questions that raise a multitude of other questions: the same may be said about clines in colour, and their possible relation to environmental gradients.

The basic material having been covered, the evolution of various traits of population dynamics is then analysed in the final seven chapters. These traits include population parameters, age structure, mating systems and competitive interactions. The account of the latter is particularly concerned with niche separation, and emphasizes the coefficients proposed for measuring the effect of one species on another. The chapter dealing with predator–prey relations reviews the evidence for adaptations of both prey and predator, and for their coevolution.

The subtitle is somewhat misleading, since "behavior" is so underplayed in the text and the emphasis is firmly upon genetics; a subtitle such as *The Integration of Population Dynamics and Population Genetics* would have been much more appropriate. The book itself is almost dauntingly large, with large pages of small type, but it does encompass most of the subject, including reviews (to 1982), and incorporates discussion of many recent concepts. Although the style of writing seldom makes the text particularly lucid, I suspect that I shall make good use of this book for reference. □

Michael B. Usher is Reader in Biology at the University of York.

*Where appropriate, the price of a book in both Britain and the United States is printed at the head of a review in *Nature*. Prices are confirmed shortly before publication of a review.

It is apparently the policy of Macmillan Publishing Co. Inc. of New York (an entirely different company from Macmillan in Britain, although, confusingly, Macmillan in Britain will from 1 May 1985 *distribute* Macmillan Inc. titles in Europe) not to divulge prices of their books over the telephone except on the authority of "the vice president and director of marketing".

Attempts to persuade Macmillan Inc. to make public the dollar prices of *Population Biology* and *Microbiology*, 4th Edn (see p. 49) have failed, and these prices therefore do not appear here. The company might consider whether this policy is in its own best interest or that of potential purchasers of its books.

New Journal

Biology and Philosophy

Editor
MICHAEL RUSE
Departments of History and Philosophy, University of Guelph, Guelph, Ontario, Canada

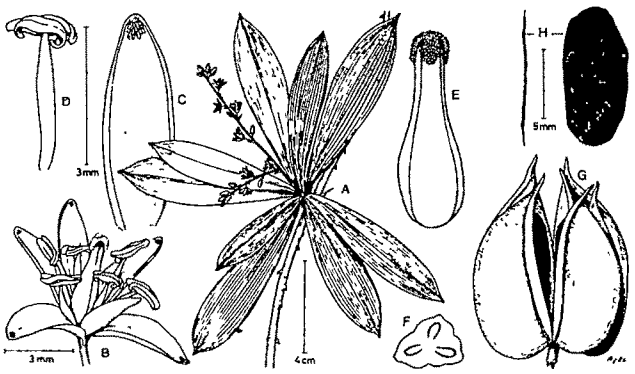
Associate Editors
FRANCISCO AYALA, *Department of Genetics, University of California, Davis*
ROBERT H. HAYNES, *Department of Biology, York University, Toronto, Canada*
and
DAVID HULL, *Department of Philosophy, Northwestern University, Evanston, Illinois*

The 1970's have seen fascinating and controversial advances in the biological sciences. One thinks, for instance, of methods for analyzing the basic molecular units of heredity; of proposals and clarifications of the appropriate methods of classifying organisms; of exciting new ideas about the nature of the fossil record and their implications for evolutionary mechanisms; and of ways in which the biological study of behavior has been extended, theoretically and experimentally, and of supposed implications for humankind. On top of these internal issues, there have been debates about biology in the world at large, for instance in education. These issues and more have made biology one of the most exhilirating areas of science, and have aroused in biologists and philosophers an awareness that there is need for meta-theoretical analysis, both about the very nature of biology (methodology and epistemology), and about its social implications (ethics).
Therefore, it seems highly appropriate now to found a journal devoted exclusively to topics in and around the philosophy of biology. *Biology and Philosophy* will help define, mold and forward thinking on the nature and implications of the scientific study of organisms. The journal will be published in one volume of four issues per year. Each issue will carry one or more discussions or comparative reviews, permitting the in-depth study of important works or topics. All articles will be subject to peer review to maintain high, impartial academic standards. Possible topics include the individual/group selection controversy; cladism; the nature of the fossil record, and its relevance for evolutionary studies; human sociobiology; evolutionary epistemology and/or ethics; moral implications of biotechnology; Aristotle's philosophy of biology; conceptual change in biology; teleology; reductionism in genetics; and more.

Call for Papers

Papers/manuscripts which fall within the above general scope are invited.

They should be sent to:
MICHAEL RUSE
Depts. of History and Philosophy,
University of Guelph,
Guelph, Ontario N1G 2W1,
Canada.
Tel. (519) 824-4120



All material will be refereed by at least two anonymous readers. Potential authors may request blind refereeing. Papers/manuscripts should be sent in triplicate, and be double-spaced.

For a sample copy please write to:

Springer guideposts to professional excellence

R.M.T.Dahlgren, H.T.Clifford, P.F.Yeo

The Families of the Monocotyledons

Structure, Evolution and Taxonomy

In cooperation with R.B.Faden, N.Jacobsen, K.Jakobsen, S.R.Jensen, B.J.Nielsen, F.N.Rasmussen

1984 225 figures XII, 520 pages
Hard cover DM 294,- ISBN 3-540-13655-X

Illustrated with more than 200 beautifully executed drawings, **The Families of the Monocotyledons** provides plant taxonomists, morphologists and evolutionists with the most comprehensive treatment of the group available today.

H.Walter

Vegetation of the Earth

and Ecological Systems of the Geobiosphere

Translated from the 5th revised German edition by O.Muise
3rd revised and enlarged edition 1985 161 figures XVI, 318 pages (Heidelberg Science Library)
Soft cover DM 44,-. ISBN 3-540-13748-3

"... a powerful stimulant for all interested in ecological research... masterful, crisp style... a concise, worldwide survey of the cause and effect chains of ecological events in which vegetation necessarily plays a dominant role... All ecologists will want to own this book; certainly they ought to." *Ecology*

Enzymes, Receptors and Carriers of Biological Membranes

A Laboratory Manual

Editors: **A.Azzi, U.Brodbeck, P.Zahler**

1984 26 figures XII, 165 pages
Soft cover DM 29,- ISBN 3-540-13751-3

Contents: Analytical Separation Techniques. - Protein Structure and Interactions. - Labeling and Crosslinking. - Reconstruction. - Spectral Techniques. - Receptors. - Subject Index.

S.Maaløe

Principles of Igneous Petrology

1985. 291 figures Approx. 500 pages
Hard cover DM 138,-. ISBN 3-540-13520-0

Designed primarily as a textbook for graduate courses, this book covers both traditional areas such as phase relations and geochemistry as well as topics which will be playing an increasingly significant role in the near future, among them nucleation and magma dynamics. Together with its generous bibliography, **Principles of Igneous Petrology** will also prove useful for students approaching the subject on their own.

F.Liebau

Structural Chemistry of Silicates

Structure, Bonding, and Classification

1985 136 figures Approx. 350 pages
Hard cover DM 163,-. ISBN 3-540-13747-5

This comprehensive, richly illustrated survey of the structures of crystalline silicates is recommended for third year students of chemistry, mineralogy, geology, and materials science. It will also prove useful as a guide for researchers and industrial chemists in their persuit of deeper, more specialized knowledge.

Coastal Sedimentary Environments

Editor: **R.A.Davis, Jr.**

2nd revised and expanded edition 1985 376 figures XVII, 716 pages
Hard cover DM 134,-. ISBN 3-540-96097-X

"... an excellent textbook for classes concerned with the geomorphology, sedimentology, and engineering of coasts. Ecologists and other more specialized biologists should also find it useful." *American Scientist*

"... an excellent choice as a textbook for a course in coastal geology... a highly readable account of coastal sedimentation that is superior to comparable texts. ..."
Journal of Sedimentary Petrology

K.O.Emery, E.Uchupi

The Geology of the Atlantic Ocean

1984 399 figures. XIX, 1029 pages
Hard cover DM 360,- ISBN 3-540-96032-5

The Geology of the Atlantic Ocean is a unique account of the geologic development of a young oceanic basin and its adjacent marginal seas. This richly illustrated, elegantly designed volume is accompanied by eleven pairs of charts summarizing data on bathymetry, physiography, seismic reflection and refraction, sediments, and tectonics.

Note: Charts are also available separately (as full set only)

Research

How to Plan, Speak and Write About It

Editors: **C. Hawkins, M. Sorgi**

1985. 55 figures. approx. 195 pages
Soft cover DM 32,-. ISBN 3-540-13992-3

Contents: Research: Why Do It? - Research: Planning and Protocol. - Searching the Literature. - Speaking at Meetings. - What the Critical Reader Looks for in an Original Article: A Guide for Writers. - Illustrating Talks and Articles. - A Guide to Statistical Methods. - Publication. - Appendix A: Suggestions for Those Intending to Present an MD Thesis. - Appendix B: How Best to Use a Dictating Machine. - Appendix C: Examples of Needless Words that Cause Verbosity. - Appendix D: American and British Usage and Spelling. - Appendix E: Abbreviations of Journal Titles. - Appendix F: Guide-lines for Putting Up Poster Displays. - Subject Index.

G. Thews, P. Vaupel

Autonomic Functions in Human Physiology

Translated from the German by M. A. Biederman-Thorson

Springer Study Edition

1984. 171 figures. IX, 384 pages
Soft cover DM 39,80. ISBN 3-540-13217-1

This introductory text treats the area of human physiology concerned with organ functions that proceed, as a rule, unconsciously, as well as the regulatory processes by which such functions are coordinated.
It is directed primarily toward medical students in the first phase of the curriculum. In designing this text, with its didactic purpose in mind, every effort has been made to keep the organization easy to follow, the presentation clear, and the figures informative; the authors have also taken pains to accentuate the most important terms to further assist the student.

G. B. Saha

Fundamentals of Nuclear Pharmacy

2nd edition. 1984. 91 figures. XXI, 287 pages
Hard cover DM 92,-. ISBN 3-540-90882-X

Thoroughly updated and expanded, this new second edition is now, more than ever, the complete text reference for students and practitioners with a professional interest in nuclear pharmacy and nuclear medicine.

From a review of the first edition: "The book is well set out and the illustrations are simple, clear and effectively complement the text. The material presented is up-to-date describing the latest radiopharmaceuticals which are routinely used in nuclear medicine... In conclusion... an excellent textbook which will be of value to all engaged in nuclear medicine. *Biopharmaceutics & Drug Disposition*

Human Physiology

Editors: **R. F. Schmidt, G. Thews**

Translated from the German by M. A. Biederman-Thorson
1983. 569 figures (most in color). XXI, 725 pages
Hard cover DM 98,-. ISBN 3-540-11669-9

"This handsome volume is a pleasure to read. It has a uniformity of style which almost challenges the reader to consume more than mere fragments. The 569 diagrams, for example, are clear and concise, black and white with judicious use of red, all with a family resemblance and superior to those found elsewhere. The typeface is restful with use of boldface type to emphasize new words as they appear. The content is all that should be found in a modern textbook... German physiologists are fortunate to have had such a textbook in the past and English speaking readers are fortunate to have it now." *Proceedings of The Australian Physiological and Pharmacological Society*

R. V. Krstić

Illustrated Encyclopedia of Human Histology

1984. X, 450 pages with more than 3050 entries illustrated with 1576 original diagrams, drawings, light, transmission and scanning electron microscopic micrographs
Hard cover DM 89,-. ISBN 3-540-13142-6

The astounding progress in histologic investigation over the last few decades and the confusing array of synonyms for important new structures and morpho-functional phenomena it has generated make Professor Krstić's **Illustrated Encyclopedia of Human Histology** especially timely. In it he provides practicing histologists, clinicians, students, and medical researchers with an invaluable reference work which defines and illustrates fundamental histologic entities and processes while enumerating variant terminology.

Dermatopathology

By **W. H. C. Burgdorf, T. Nasemann, M. Jänner, B. Schütte**

1984. 374 figures. X, 222 pages
Hard cover DM 98,-. ISBN 3-540-96011-2

Basic concepts in dermatology and pathology are presented in this concise text. Organized with first-year dermatology and pathology residents in mind, its introductory chapters and illustrations stress conditions most commonly encountered by first-year residents.

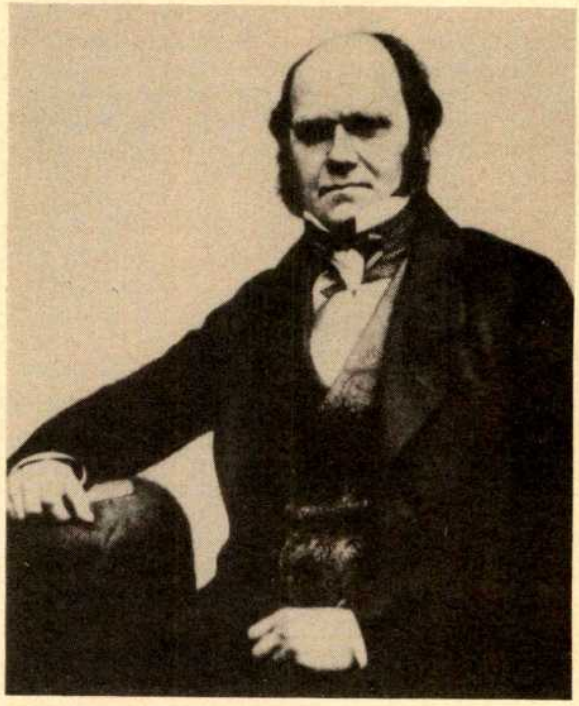
The Correspondence of Charles Darwin



Edited by **FREDERICK BURKHARDT** and **SYDNEY SMITH**

This unique new series will be the first complete edition of the correspondence of Charles Darwin (1809–1882). It will publish the full text of both sides of Darwin's correspondence and includes numerous letters to Darwin, which have been newly discovered as the result of an intensive and extensive search by a number of learned scholars.

Volume 1 : 1821–1836

The first volume begins with a letter received by the twelve year old Darwin whilst a Shrewsbury schoolboy and ends with the highly readable correspondence on the results of the Beagle voyage. The letters to Darwin include all that have been preserved from his correspondence with friends and members of his family. However, the major correspondence in the volume, both in quantity and quality, relates to the Beagle voyage. The letters tell a remarkable story of self-discovery and preparation for a life dedicated to science.

Parts of phycology

Howard Pearson

Introduction to the Algae, 2nd Edn.
By Harold C. Bold and Michael J. Wynne.
Prentice-Hall: 1985. Pp.720. $53.95, £49.15.

UNDERGRADUATES requiring an up-to-date text on the algae, which concentrates on cell structure, reproduction and classification, will benefit greatly from this factual, well-written, concise and well-presented book. Researchers who spend most of their time "torturing" the physiology and biochemistry out of algal cells, but want to know how their "tame" species fit into the greater scheme of things, will also profit from reading it.

The book was not written to cover all aspects of modern phycology (a point acknowledged by the authors), but to complement other texts on algal ecology, physiology, biochemistry and genetics. In this respect it is not adequate for an introductory phycology course, or for students attracted primarily to the algae by an interest in their potential biotechnological applications.

This second edition retains the format of the first, with an outstanding introductory chapter (worthy in itself of publication as a booklet) preceding accounts of the algae division by division. The blue-green algae are included, as are new sections on *Prochloron* and algae of uncertain affinity. There are also other minor additions and changes to some of the keys. Mercifully, Bold and Wynne have dropped the unnecessary "phyco" from the algal division names so that, for example, the Chlorophycophyta revert to being the Chlorophyta. The glossary of terms is retained and aids the use of the simple-to-follow keys to the genera of each division, while the updated reference section provides a good lead into further reading. However, I regret the deletion in this edition of the very useful appendix on culture methods as the basic information greatly helps those embarking on the culture of algae.

In all this is an excellent book, full of useful pieces of information. The many photographs and line drawings complement the text and merit special praise. Bold and Wynne have managed to bring alive what even to many dedicated phycologists is a less than stimulating, albeit essential, area of the subject. □

Howard Pearson is a Lecturer in the Department of Botany at the University of Liverpool.

Eye to revolution

C.J. Leaver & S.M. Smith

Plant Molecular Biology.
By Donald Grierson and Simon Covey.
Blackie/Chapman & Hall: 1985. Pp.176. Hbk £17.95, $39.95; pbk £8.95, $17.95.

THE application of recombinant DNA techniques to the study of plant biology has led to the establishment of the new field of plant molecular biology. Yet it is only now that a book on the subject can be justified by the available data. In this short and up-to-date summary, Grierson and Covey have succeeded in conveying the present state of knowledge, as well as indicating the potential for genetic modification of higher plants which has raised hopes for a new green revolution.

The basic structures of plant genes are not dissimilar to those found in other organisms. However, the exciting questions in molecular terms arise from the presence in the plant cell of three interdependent genetic and protein-synthesizing systems, coupled with the unique developmental characteristics of higher plants.

The first chapter is a brief, obligatory introduction to recombinant DNA technology, which like the rest of the book would have benefited from the inclusion of a glossary to explain some of the necessary jargon. Subsequent chapters deal with the structure, organization and expression of nuclear, chloroplast and mitochondrial genomes. The chapter on hormonal and environmental factors affecting gene expression reflects our level of ignorance in this important area, and is disappointing in its lack of coverage of some of the better understood aspects of the responses of plants to stress, such as heat shock and anaerobiosis. The accounts of plant–bacterial interaction in nitrogen fixation and in the natural gene transfer system of the *Agrobacterium* Ti plasmid are excellent introductions to each subject, as is that describing plant viruses, and lead logically into a final discussion of the prospects for genetic engineering of plants. This chapter illustrates the fact that although it is possible to list some of the goals for plant improvement, we still have little idea of the identity or mode of regulation of the genes we might modify or transfer.

The text contains errors, but this failing is partly compensated for by the up-to-date bibliography which allows ready access to original papers. The authors have produced a book which provides a solid basis for undergraduate courses on plant molecular biology, and which will also be useful to the inquisitive, postgraduate and the informed entrepreneur requiring scientific background on the investment potential of plant biotechnology. □

C.J. Leaver is Reader in Plant Molecular Biology and S.M. Smith is Lecturer in Plant Biotechnology in the Department of Botany, University of Edinburgh.

Chloroplasts, new and improved

R.P.F. Gregory

Chloroplasts.
By J. Kenneth Hoober.
Plenum: 1984. Pp.280. Hbk $42.50, £40.38; pbk $19.95, £19.
Chloroplast Metabolism: The Structure and Function of Chloroplasts in Green Leaf Cells, revised edn.
By Barry Halliwell.
Oxford University Press: 1984. Pp. 259. Hbk $50; pbk £9.95, $15.95.

IN THESE difficult times, when there is pressure to deliver courses that get to the point and stick to it, what usually gets left out is the sense of historical development of the present-day ideas, and all except the most sketchy treatment of comparative biology. It is a delight to find Hoober's text affirming at the very start his historical perspectives in a survey of the early stages of microscopy, chemistry and physics, and offering a challenging overview of the diversity of chloroplasts in algae as well as in higher plants. The work is well illustrated, with well-produced electron micrographs and line drawings. Equally welcome is the reappearance in paperback form of Halliwell's monograph; the reduced price will make this a more realistic prospect for the undergraduate.

The two books start off covering much the same ground, and present competent accounts of the structures, components and processes that make up the "light" and "dark" parts of photosynthesis. They also include practical details on such matters as chloroplast isolation which are likely to be found valuable by researchers and teachers.

From then on each author follows his personal interests. Halliwell is very strong on the interrelationships of photosynthetic metabolism, discussing at length (and with his practical interest) the pathways of C_3, C_4 and CAM photosynthesis and their control, the roles of the chloroplast envelope and of its shuttle systems, and providing discussions of oxygen toxicity and polyphenol production. Hoober on the other hand presents a major coverage of his speciality of chloroplast genetics and protein synthesis, including the difficult questions of the cooperation between the genomes and protein synthesis of nucleus and chloroplast (topics which Halliwell chooses to leave out except for a very brief note as an appendix). It is of course traditional to distinguish genetics and protein synthesis from metabolism, but this tradition is rapidly dissolving as the DNA workers prove themselves increasingly able to solve metabolic questions. Hoober concludes with a discussion of the evolutionary relationships of organelles and bacteria, and describes in some detail (and with further challenging questions) the work in progress on relating common sequences in proteins and in DNA, and so he returns to his initial theme of unity and diversity in this microcosm of Nature.

Halliwell's publisher is perhaps taking some licence in terming this a revised edition: there is in fact virtually no change of any substance (the pagination nowhere differs by more than one page from the original edition), and indeed Halliwell claims only to have made corrections and a few updates. He has provided some additional references to the literature, chiefly in the sections describing the Calvin cycle and photorespiration, but he has not incorporated the recent advances in (for example) the oxygen-evolving system, nor in the chloroplast genome. Nevertheless within its terms of reference Halliwell's book still stands up well to comparison: for example, on the question of the transport of metabolites across membranes, he indexes both the C_3 translocator and the dicarboxylate translocator, and discusses their roles in the export of NADPH and ATP. By contrast Hoober is very brief here, referring only to the phosphate translocator in connection with triose phosphate export. Such key terms, including also transketolase and the names of important metabolites and enzymes, are printed in Hoober's text in bold type, but surprisingly do not always appear in the index.

Both books clearly have their strengths, and will be needed by the teacher of biology, biochemistry and botany. The student who is unwilling to purchase both will have to judge carefully where his interests lie. □

R.P.F. Gregory is Senior Lecturer in Biochemistry at the University of Manchester.

Spring books

The next review supplement to appear in *Nature* is Spring books on 25 April.

The books to be reviewed include *Kapitza, Rutherford, and the Kremlin* (by Lawrence Badash); *The Problems of Evolution* (by Mark Ridley); *Time's Arrows* (by Richard Morris); *The Beginnings of the Nobel Institution* (by Elizabeth Crawford); *State of the World 1985* (by Lester R. Brown *et al.*); *The Broken Brain* (by Nancy Andreason); *Nuclear Winter* (by Mark Harwell); and *"Surely You're Joking Mr Feynman!"* (by Richard Feynman).

Green workings

J.D. Ross

The Physiology of Flowering Plants: Their Growth and Development, 3rd Edn.
By H.E. Street and Helgi Öpik.
Edward Arnold: 1984. Pp.279. Pbk £9.95.
Advanced Plant Physiology.
Edited by Malcolm B. Wilkins.
Pitman: 1984. Pp.514. Hbk £17.50, $17.50; pbk £14.95, $14.95.
Class Experiments in Plant Physiology.
By Hans Meidner.
George Allen & Unwin: 1984. Pp.169. Hbk £20, $35; pbk £9.95, $15.95.

WHEN they come to buy or use a book, the novice, the advanced student and the teacher have very different requirements. The beginner needs a broad coherent text which also brings out the excitement of the subject. The advanced student needs a detailed, balanced exposition and a lead into the current literature; whilst the teacher needs reassurance, a stimulus, and often a little help from his friends.

Perhaps the most difficult book to write well is the first, the "easy" one for the new student. In this third edition of *The Physiology of Flowering Plants* Helgi Öpik has based her text closely on successful earlier editions and concepts developed with her co-author, the late Professor Street. With minor flaws, she has succeeded admirably. The book flows through the subject with a nice style and conveys enthusiasm without avoiding uncertainties and controversies. Starting logically with seed imbibition and germination we are quickly introduced to the interrelations of axis and storage tissues. The accepted dogma is outlined and then the criticisms are aired, for which the author must be given credit and respect for her feeling that the initiate should be exposed to problem areas. With emphasis on whole-plant physiology, we are led through photosynthesis, water relations and nutritional aspects in clearly written chapters.

An interesting account of stress physiology is then followed by discussion of the various aspects of growth and development. Again difficulties are not ignored; for example on page 184 there is a section headed "The problem of the mode of hormone action" (other texts do not even admit to a problem). This is exactly the treatment needed by the new undergraduate; it will inform and interest. Sadly, the diagrams and figures are small and mean, a major fault in many British publications.

In the preface to *Advanced Plant Physiology*, Professor Wilkins gives his opinion that a cooperative effort is necessary in compiling a text for the advanced student. This approach indeed gives strength in one sense. Unfortunately it is also the root of many of the book's weaknesses and the 20 contributions vary widely in treatment and usefulness. From my differing degree of enjoyment in reading the various parts I suspect that Wilkins with, perhaps, his colleague John Hillman could have written a more acceptable book on their own. Chapters such as theirs, on gravitropism and apical dominance, successfully put across ideas and experimental approaches in a manner suitable for their intended audience. It is at

the student, not the researcher, that this text is aimed and balanced coverage is vital. This is not achieved in many of the contributions, although the editorial choice of subject divisions makes such a failing unavoidable.

The opening five chapters unashamedly tackle the "hormones", largely in a biased and sometimes dogmatic manner. The material contained here may indeed be recent, but the philosophy is still that of Frits Went. These accounts are not without scholarship, some being good reviews, but they deal with relatively narrow areas often of marginal relevance to normal plant growth. Also there are slips in terminology which annoy rather than confuse (although some are misleading, such as the use of "vernalization" for "stratification"; some plants can be vernalized as a seed, but this is a very different phenomenon to dormancy breakage).

I did not greatly enjoy this part of the book but found the rest of it more satisfying, albeit with some exceptions. The discussions of growth movements, rhythms, water relations and mineral nutrition are well constructed. Photosynthesis, however, is covered in a peculiarly unbalanced manner with aspects as important as C_4 metabolism and photorespiration being squeezed into the last two pages. Another odd component is the chapter on phytochrome — the undergraduate basing his studies on this is going to need guidance as, I suspect, will many lecturers. If this chapter is meant to be balanced by that following, on photomorphogenesis, it fails; here are the views, and largely the work, of one laboratory with little regard for other opinions. In contrast, the rather neglected phenomena of juvenility, photoperiodism and vernalization are well described and reviewed in a readable fashion, and are followed by straightforward accounts of germination, senescence and abscission.

Parts of this book are very good. But those using it must be supported by teachers unafraid to dispute the written word, so readily accepted by students.

Hans Meidner has written *Class Experiments in Plant Physiology* for those who teach the subject. Over the years a number of laboratory guides in plant physiology have appeared, usually emanating from the United States and written for students. These have not proved popular in Britain where there are smaller classes and different pressures. This time the collected experience of successful teachers and the author's attention to detail will be gratefully received. Class experiments in plant physiology, within the constraints of the timetable, are notoriously difficult. The suggestions, advice and hints contained here will be of great use to both the experienced practitioner and the new lecturer — if there are any out there in these hard times! □

Membrane biology moves on

M.J. Selwyn

Membranes and their Cellular Functions, 3rd Edn.
By J.B. Finean, R. Coleman and R.H. Michell.
Blackwell Scientific: 1984. Pp.227. Hbk $19.50; pbk £9.80.

MEMBRANE biology has advanced rapidly in the five years since the appearance of the second edition of *Membranes and their Cellular Functions*, a book which covers a course in membrane biology at first- or second-year university level more completely and satisfactorily than most of its competitors. A revised edition is therefore both welcome and timely.

Much of the material is included in that excellent tome *Molecular Biology of the Cell* by Bruce Alberts *et al.*, but this is less convenient because of its weight and because the information is scattered through the book. Robertson's *The Lively Membranes* is stimulating but very much slanted towards bioenergetics, while Harrison and Lunt's *Biological Membranes* or Houslay and Stanley's *Dynamics of Biological Membranes* are pitched at a more advanced level.

This edition has grown in length and content, and the need for growth can be readily appreciated by comparing the chapters "Recognition, Response and Communication", "Secretion, Endocytosis and Lysosomes" and "Biosynthesis and Turnover" with their counterparts in the second edition. Together with a new chapter on membrane variations and membrane pathology, these are where the most expansion has been made, to include, for example, extensive descriptions of receptor mechanisms and the biosynthesis and processing of proteins which are incorporated into or pass through membranes. The chapters on membrane structure, and composition, and on ion and solute movements have also been thoroughly up-dated, but the treatment of the physical chemistry of ionic equilibria still lacks rigour.

The authors' style is readable and the layout — a central text with wide margins containing topic titles on one side, diagrams and equations on the other — makes for easy reading, browsing or reference. Overall this is an excellent volume, accurately written and attractively presented.

M.J. Selwyn is Dean and Senior Lecturer in the School of Biological Sciences, University of East Anglia.

Roger Hill

Genesis on Planet Earth: The Search for Life's Beginning, 2nd Edn.
By William Day.
Yale University Press: 1984. Pp.299. Hbk $49, £35; pbk $14.95, £12.95.

THERE is no better example of the inadequacy of a multidisciplinary approach to an interdisciplinary problem than in the search for probable origins of life. Progress depends as much on the breadth of understanding and synthetic abilities of individuals as it does on the design of relevant experiments or on sagacious observation. Such qualities are demanded in equal measure from commentators on the field, and William Day is clearly competent to provide us with a useful review of current results, theories and speculations.

The conceptual dimensions of the subject call for an iterative development, and the repetition of subject matter in new contexts is a welcome feature of the book. For example, Day has chosen the fossil record as his first substantive topic, and the prokaryote-eukaryote distinction introduced here is fully described again after much compressed information on the cellular and molecular basis of life. After two chapters on bioenergetics, the reader is ready for a scientific presentation of the problem, and a review of prebiotic syntheses of present-day biomolecules follows. The crux of the matter, the interface between prebiotic chemistry and biochemistry, is seen to be the abiotic polymerization of preformed nucleotides. Encapsulation by lipid bilayers and rudimentary photosynthesis gives life in slow motion before the development of protein synthesis and the appearance of enzymes. Extraterrestrial life is considered briefly, and the twenty-seventh of 28 short chapters is devoted to the organic analysis of meteorites.

Inevitably, subject specialists will find much to disagree with in the detail of this wide-ranging review, and many chemical evolutionists will regard as implausible the claim that not only are present-day polynucleotides essential prerequisites for life of any kind, but also that they could appear spontaneously as the outcome of a sequence of highly probable prebiotic syntheses. But there is much enjoyable and stimulating reading here. Day's historical and statistical perspectives, his descriptions of possible pre- and early-life scenarios and his speculations on the nature of future evolution are more than sufficient to encourage the reader to persist through the occasional conceptual thicket.

One caution to students: the author frequently presents conjectures in the style of factual statements which, though easing the narrative, calls for an assiduously critical presence of mind. □

Roger Hill is Reader in Chemistry at the Open University.

Our own inheritance

Ben Carritt

Human Genetics. By Elof Axel Carlson.
D.C. Heath: 1984. Pp.432. $27.95.
Patterns of Human Heredity: An Introduction to Human Genetics.
By James R. Brennan.
Prentice-Hall: 1984. Pp.340. $35, £31.90.

IT SHOULD not be imagined that a reviewer's heart beats faster with the arrival of a book based on a one-term course for non-science students. Moreover, chapter headings such as "Reflections on the Human Condition" (Carlson's first) fill the cynical and hard-bitten experimentalist with dread. And in Britain, where the contribution of science faculties to liberal studies teaching is negligible, it is tempting to dismiss such books as an irrelevancy. I was therefore pleasantly surprised by how much I enjoyed reading the first of the two reviewed here.

Carlson's *Human Genetics* is indeed intended as an introductory text for students with "no prior science course work", and the treatment of many important areas is therefore necessarily superficial. In some cases, additional depth is provided in the form of extensive legends to the excellent figures, and in others the details are contained in tables. At times, this device deprives the author of the space to explain his point with sufficient clarity: it also tends to give the impression that the transmission of scientific knowledge is not the primary purpose of the book. In a sense, it would be as well if this were the case, because viewed strictly as a genetics text it can be faulted. I thought, for example, that the coverage of chromosome abnormalities was too sketchy, and that there was too much developmental biology. Neither could I see the reason for inserting an account of radiation damage as the third chapter when mutation is not covered until much later on.

Yet this is an immensely readable book, which seems to revel in the opening of controversy where almost any kind of biological principle is involved. IQ testing, the genetics of skin colour, the genetic basis of race and the "eugenics" programme of the Nazis are obvious inclusions, but there are many others besides. I particularly enjoyed the nuggets of useful statistical information, included in tabular form, such as the changing patterns of mortality, the causes of mental retardation in mental patients and so on.

Patterns of Human Heredity, aimed at a similar audience, is very much more a genetics text. The structure of the book is logical, proceeding through cell structure, DNA and chromosomes to Mendel, and then on to genetic diseases, polygenes and population genetics. The later sections of the book are well handled, particularly those which are mathematically based, such as polygenes and population genetics. One wonders, however, whether they might not be too advanced for a readership which is considered to be in need of the sort of detailed description of human reproduction which appears earlier in the book.

I found Brennan's use of language annoying and sometimes difficult to understand, but this may be a personal or a national difference in usage. Both he and Carlson provide review questions and summaries for each chapter — useful learning aids. Brennan also gives answers to his less discursive questions, which is helpful, if repetitive. □

Ben Carritt is in the Medical Research Council's Human Biochemical Genetics Unit, London.

Genetic similarities

D.J. Cove

Genetics, 2nd Edn.
By Charlotte J. Avers.
Willard Grant/Wadsworth: 1984. Pp.644. $27.50, £13.95.
Genetics, 3rd Edn.
By Ursula Goodenough.
Holt Saunders/Holt, Rinehart & Winston: 1984. Pp.894. Hbk £24.95, $37.95; pbk £13.95.

THIS is the third opportunity I have had to review the annual crop of introductory genetics textbooks for *Nature* (see *Nature* **289**, 702–704 (1981) and **295**, 476–477 (1982) for earlier reviews) and I will not repeat here in detail my views on how I believe genetics teaching should cope with the integration of the classical concepts of the subject with the explosion of knowledge that has taken place as a result of molecular analytical techniques. This year's books are new editions rather than new texts and so it would be surprising if either offered any radical change in its teaching strategy. Avers remains an example of the "Mendel before molecules" approach while Goodenough is a "Let's start with DNA" book. Although the two authors have adopted what at first sight appear to be completely different teaching strategies, these books illustrate clearly how such overall strategies are rather unimportant. Each contains a chapter on Mendelian inheritance and there is little difference between them. Both stick faithfully to history, introducing Mendelism with Mendel and so, like most other textbooks of genetics, the student is required to cope all at once not only with segregation but also with diploidy and dominance. Both texts give the initial impression that each gene is represented by only two alleles, one dominant to the other, although Avers introduces multiple alleles and incomplete dominance much sooner than Goodenough. In both books, Mendelian genetics is set in a sealed compartment with little reference to modern knowledge of gene structure or function.

Population and evolutionary genetics are also treated similarly in both texts. The subjects are dealt with last, in another compartment almost like an embarrassing appendix. Set against the excitement of recent advances in genetics at the molecular level, it is now often difficult to interest students in population and evolutionary genetics even though these topics remain of central importance to the subject. The integration of these topics into the general body of genetics teaching is therefore crucial.

As is to be expected, the most significant changes which these two new editions incorporate is in the area of molecular genetics and both include an up-to-date account of modern techniques for the handling and analysis of DNA and of the findings to which these new techniques have led. Here Goodenough, building on the strength of the molecular and microbial side of her earlier editions, has the edge.

The treatment by both texts of the regulation of the use of genetic information and of the genetic programming of development remains anecdotal. Perhaps the most important principle to emerge out of the study of the regulation of gene expression is that general principles are sparse. The diversity of regulatory mechanisms involved in the control of metabolism is not stressed enough in either book, and, in both, developmental regulation consists of the best stories told in an unrelated manner. Here Avers, perhaps because she has less space, achieves slightly more integration. Except of course in the treatment of Mendelian genetics, neither book gives much space to plants. Avers in her table of the DNA content of "representative eukaryotic genomes" includes no green plant!

As our knowledge of genetics becomes more detailed, the subject becomes more challenging to teach especially in introductory courses. Conventional approaches become less satisfactory and integration more difficult since there is so much to be integrated. I believe that it is now best to begin such a course with a fairly complete but largely uncritical review of our current state of knowledge and then to deal with the experimental evidence which supports this overview, at the same time building flesh onto the initial skeleton. Neither of these texts adopt this approach. Both in fact offer us the same recipe as before and although they include all the necessary new ingredients the flavour is not much changed. If you liked either of these books before you should like the new editions more. If you are a first time buyer, however, I do not think they are among the best buys. □

Cells and the single author

J.G. Edwards

Cell Biology, 2nd Edn.
By Gerald Karp.
McGraw-Hill: 1984. Pp.896. $35.95, £29.95.
Cells and Organelles, 3rd Edn.
By Eric Holtzman and Alex B. Novikoff.
Holt Saunders/Holt, Rinehart & Winston: 1984. Pp.660. £24.95, $32.95.

THE acclaim which greeted the publication of *Molecular Biology of the Cell*, by Bruce Alberts and five other authors (Garland, 1983), was not solely a response to the excellence of its parts. As Joseph Gall pointed out in his review (*Nature* **302**, 637; 1983), the inclusion of material on development, the immune and nervous systems and special features of plants, pointed to ways in which the teaching of biology at the cellular and molecular levels might be better integrated. In comparison, the narrower horizons of earlier textbooks may seem to do less than justice to the essential unity of modern biology, so one looks at their new editions for compensatory virtues.

Karp's book shares with Alberts's a much stronger component of molecular genetics than used to be found in texts entitled *Cell Biology*, but despite its new cover photograph of a myogenic clone still lacks Alberts's strong foray into developmental biology. Where both Karp and Alberts cover the same ground, however, the former more often manages to give some insight into experimental origins. For example, Alberts will tell you how many ribosomal genes there are in a *Xenopus* oocyte, but not about the anucleolate mutant; that allolactose is the real inducer of the lactose proteins in *E. coli*, but not about the diploids which helped unravel the system. Karp sometimes also has the edge in significant details (not just on matters such as oncogenes, where the passage of two years naturally makes all the difference).

In most areas with which I am familiar the reliability seems high, although I am unhappy about the way in which Karp presents the Hayflick phenomenon, both by discussion and juxtaposition, as the result of defective cellular processes. A balanced account would surely include the idea of programmed cell-death, and thus make better sense of immortalizing mutations. Karp's micrographs and diagrams (the latter now in two colours) are excellent. The whole is an impressive achievement, which runs Alberts much closer than I had imagined possible and will strongly tempt those of us who share the author's view of the importance of experimental history for current understanding.

The shorter *Cells and Organelles* is closer in content to a traditional cytology textbook, and much gentler with the molecular aspects. Controversial areas get balanced, essay-like discussion and there are virtues of a reflective kind. You have to look in Part III of Alberts to understand Karp's cover picture, but only Holtzman and Novikoff point out that this revelation of the route to multinuclearity was one of the early triumphs of cell culture. Small unreliabilities disturb confidence, however: a diagram of skeletal muscle in which the muscle fibres are drawn to look like fibrils; another of a hepatocyte with empty space labelled for a microfilament; EGF named epithelial growth factor; pyruvate produced anaerobically from glucose. In the review copy a number of micrographs are much too dingy for clarity and impact, and some are patchily unsharp.

A reviewer should perhaps be wary of laying emphasis on how a textbook handles his own small favourite corner. Nevertheless, the time has surely come for better treatment than can be found in any of these volumes (including, surprisingly, Alberts) of the real progress which has been made towards identification of the molecules which join cells together. If any reader is busy revising another textbook, or wants to know about this topic for other reasons, my advice is to ignore most of the secondary literature, and give due attention to the strategy first adopted by Gerisch and also put to such good effect by Gerald Edelman and others. □

DNA in sound and vision

E.J. Wood

The Techniques in Genetic Engineering Video Library.*
Series editor R. Williamson.
IRL Press: 1985. PAL in VHS and Betamax, £85, $170 each tape, £640, $1,280 the set. Supplementary charge for PAL in U-Matic and NTSC and SECAM standards conversions.

LAST year I reviewed the first videotape in this series (*Nature* **309**, 566; 1984). Now that the whole series is available, how do the programmes live up to the initial promise of that first tape?

Each of the seven subsequent programmes concentrates on a specific technique or a limited area, and lasts 20–30 minutes. After the introduction of the presenter ("an expert in this field") by Professor Williamson, there is a brief and generally clear account by the expert of *why* a particular technique is of value, and usually some graphics are used to demonstrate in detail how DNA etc. is cut up and manipulated. These individuals mostly do not look directly at the camera, which I found somewhat annoying, while the level of background noise in some of the sequences is unduly obtrusive at times. These sections move fairly rapidly and would not easily be absorbed by the student at the first sitting. But then the video can be "stop-framed" or replayed, until the details are clear. The graphics themselves are quite well done, although they cannot be said to use animation to its fullest extent, at least in the earlier tapes.

The tapes can be viewed in any order, although most people are likely to do cDNA cloning first. Several times demonstrations are repeated — for example, preparing DNA by ethanol precipitation, making cells competent by adding $CaCl_2$, electrophoresis on slab gels and baking nitrocellulose filters in an oven. Maybe each is appropriate at that particular juncture, but given the cost of the whole set of programmes so many repeats were perhaps unnecessary.

A more general, but more serious point, is that in places too much detail is given about a technique, so that the underlying message becomes obscured; for example, it cannot really matter very much that the buffer reservoir of a slab-gel apparatus holds 0.8 litre of buffer, and excessive attention is paid to the disposal of radioactive pipette tips. Still, the demonstrations of techniques are indeed on the whole of high quality: the only exception to this is the demonstration of the microforge, which is poor but probably technically difficult to show.

In order to benefit fully from the tapes students would have to work through each a number of times, stopping and starting as necessary, probably writing down the sequences in the graphics. At this level I feel they would learn quite well from the tapes alone. The prize for the best and clearest tape goes to *Oligonucleotides*, closely followed by *Microdissection and Microcloning*, while the worst missed opportunity was in animating nick translation which could have been done so much better. But this must have been a difficult project to mastermind, especially to judge how much to put in and in what detail, and overall the tapes do succeed in their aim of being a "self-paced teaching aid". □

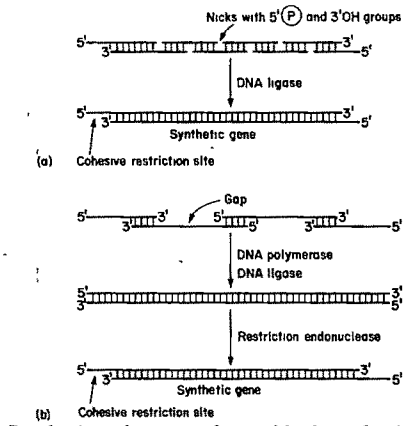
Bacteria, Plasmids, and Phages: An Introduction to Molecular Biology.
By E.C.C. Lin, Richard Goldstein and Michael Syvanen.
Harvard University Press: 1985. Pp.316. Hbk $35, £34.95; pbk $18.50, £18.50.



From Cells to Atoms: An Illustrated Introduction to Molecular Biology.
By Anthony R. Rees and Michael J.E. Sternberg.
Blackwell Scientific: 1984. Pp.94. Hbk £12, $12; pbk £6.80.

AS recombinant DNA techniques continue to stride forward there is an ever-growing movement to introduce this subject and its relationship to molecular biology at all levels of undergraduate teaching and in a wide variety of disciplines. There is also a strong demand for textbooks to cover the scope of the relevant techniques and the insights they have provided. But this need has disguised the fact that recombinant DNA is an "illustrator" of the systems it is used to investigate, and as a system *per se* has less intrinsic value; indeed, in many cases, the continued development of recombinant DNA techniques has depended upon the knowledge dissected from the biological systems under investigation. All this argues for an integrated approach to the teaching of recombinant DNA and genetic engineering in which the techniques cannot be divorced from the biology.

Nowhere are these dilemmas more painfully visible than in Alan Emery's *An Introduction to Recombinant DNA*. From the beginning Emery declares that he has not set out to write a textbook of molecular biology (of which, he adds, there are many good examples on the market). But, within a few pages, he is forced to explain DNA replication and subsequently, in the second chapter, genome organization has to be covered along with translation and transcription. The use of recombinant DNA techniques for the analysis of gene structure and function (Chapter 4) forces explanations of pseudogenes, transposons and multigene families until, at last, the author has lost the battle and the book reverts to a more integrated approach — describing various facets of recombinant DNA techniques within the context of molecular biology. Globin gene organization, immunoglobulin genes and oncogenes are all covered in following chapters, which discuss the molecular pathology of unifactorial genetic disorders and the molecular pathology of common diseases.

By now, it is apparent that the book is severely medically orientated and it continues in this vein. *An Introduction to Recombinant DNA* might more correctly be described as a textbook on molecular biology in medicine. This is not a thorough or careful account of recombinant DNA techniques — despite their probable importance in the future, some techniques such as embryo microinjection and the use of transgenic mice receive a most cursory mention — and the application of recombinant DNA in other disciplines is confined to a single, short chapter at the end of the book.

Roger Warr's *Genetic Engineering in Higher Organisms*, a volume in Edward Arnold's *Studies in Biology* series, concentrates on a wide range of higher systems and thus provides a more comprehensive coverage of methods for transferring genes into animal and plant cells. It therefore might seem to complement Emery's book. However, given the limited space available to the author within the pocket-book format of this series, the treatment of the subject is necessarily light and students will need to consult some of the texts provided in the reference list for a more detailed grasp of the systems described. In the same series, Brian Clark's *The Genetic Code and Protein Biosynthesis* has been revised and updated to provide what is almost the pocket version of Adams *et al.'s The Biochemistry of the Nucleic Acids* — a brief but clear and very historically orientated account of the elucidation of protein biosynthesis. Initially, I rebelled against the historical treatment, but the story illustrates the intermingling of biology and techniques that is the keenest approach to molecular biology. Still, some students, begging for final answers, may find this historical approach somewhat tortuous.

Synthesis of genes from blocks of oligonucleotides. The diagram is taken from Gene Cloning: The Mechanics of DNA Manipulation *by David M. Glover, published by Chapman & Hall/Methuen.*

Clark resists the temptation to introduce a mandatory chapter on recombinant DNA, but no such restraint has been shown by Lin, Goldstein and Syvanen in *Bacteria, Plasmids, and Phages.* The book is subtitled (in rather large letters, I might add) *An Introduction to Molecular Biology,* something that it patently isn't. This is a general introduction to microbiology with the emphasis on bacteria and its associated plasmids and phages. Bacterial genetics and genetic control systems, plasmid genetics, phage genetics and development are covered and there are cursory descriptions of some aspects of molecular biology, for example transcription, translation and allosteric enzymes. The book is very comprehensive but not especially detailed, so, for example, the decision pathway of lambda lysogeny is covered in a couple of pages. This is a basic primer for a bacteriology/virology course, with enough basic molecular biology thrown in to prevent the student's understanding of bacterial and viral systems from breaking down. A short chapter, "DNA Restriction and Gene Cloning", cannot make up for the absence of any discussion of the use of recombinant DNA in analysing bacterial or viral systems. Once again integration may have proved the better course.

A most refreshing aspect of Rees and Sternberg's book is that it does not claim to be anything it isn't. This is almost a coffee-table account of molecular biology, containing 44 sections dealing with topics from cell structure to gene organization. The structure of various macromolecules is covered in some sections and the book finishes with sections on muscle action, nerve action and the action of hormones and antibodies. Using a large-page format, each section takes up two facing pages and includes an extensive diagrammatic explanation which is accompanied by clear, concise notes illustrating the major points. The diagrams are of superb quality, managing to convey on the two-dimensional surface of the page, the four-dimensional dynamic quality of the processes they describe. Accompanying the diagrams a carefully measured text makes this a useful volume. However, it is not a textbook to be used in isolation — it will serve its purpose best as an adjunct to other more standard and comprehensive works.

If the measure of current textbooks on molecular biology, particularly with reference to recombinant DNA, may be taken from the present crop, then with one or two exceptions they seem generally of low standard. In part this stems from the apparent desire to be topical. But topicality alone cannot serve the interests of student or teacher in molecular biology. □

SCIENCE AND SCEPTICISM

by John Watkins

This is an original contribution to some of the central questions of epistemology.

'Immodestly stated, my purpose is to succeed where Descartes failed; to submit our knowledge of the external world to an ordeal by scepticism and then, with the help of the little that survives, to explain how scientific rationality is still possible.'
— from the author's preface

The book will be vital reading for anyone concerned with the rationality of scientific thought.
Publication April '85, £25.00 cased, (09 158010 2)

Antibodies: Their Structure and Function.
By M.W. Steward.
Chapman & Hall/Methuen: 1984. Pp.96. Pbk £3.50, $7.50.
Introduction to Molecular Immunology, 2nd Edn.
By Alfred Nisonoff.
Sinauer/Blackwell Scientific: 1984. Pp.236. Pbk $14.95, £12.80.
Molecular Immunology: A Textbook.
Edited by M. Zouhair Atassi, Carel J. van Oss and Darryl R. Absolom.
Dekker: 1984. Pp.725. SwFr.129, $47.

IN THE past few years recombinant DNA technology has made a tremendous impact on our understanding of the immune response. This revolution is still accelerating as the T cell receptor, differentiation antigens and lymphokines are cloned and sequenced. Textbooks on "molecular immunology" appearing now — and written a year or two ago — are thus in danger of appearing outdated to those whose imagination is caught by today's excitement. At the time these three books were prepared, however, the new technology had been applied to antibodies and MHC antigens. So readers should not be disappointed, because these structures lie at the heart of the discipline.

The most concise and aptly titled of the three books is Steward's *Antibodies: Their Structure and Function*. The perspective is biochemical, with a clear and detailed account of the structure of immunoglobulins. The functional properties are discussed at the level of the antibody molecules, with equal attention being given to their ability to bind antigen at one end and to trigger secondary events at the other. The nature of the antigen binding is discussed particularly well and is the book's strongest point. Less attention is given to molecular genetics, although the essential features are covered. This is a solid and well written book, suitable for undergraduate biochemists or immunologists. It should serve as a good introductory text and has a plentiful bibliography.

Nisonoff's *Introduction to Molecular Immunology* is a superb book. It concentrates mainly on immunoglobulins and takes the reader carefully through the antibody molecule, from its binding properties to primary and three-dimensional structure and on to genetic control. Starting from first principles, including a brief description of the cellular background, it should be fully comprehensible to most biologists. The clarity of the text is not the result of over-simplification and the reader is taken up to the front line in research as it was in January 1984. The illustrations are good and always help to clarify the text.

This is the second edition of an already successful book and author and publisher are to be commended on the rapid appearance of the updated version. The new edition has been expanded by extensive rewriting of the chapter on complement and inclusion of a new chapter on the major histocompatibility complex. The latter is written with the same emphasis on biochemical and genetic information and has a brief introduction to explain why the MHC is important. This book will appeal to students at all levels, making an excellent introductory text for undergraduate courses and a useful revision text for those of us who have not followed this literature closely. I look forward to the third edition, hoping that new chapters on the T cell receptor, differentiation antigens and lymphokines will be added and explained with the same clarity.

Molecular Immunology, a multi-author work, is aimed at graduate courses and is much broader in scope than the two books discussed above. Unfortunately it seems to have taken longer to appear and recent advances make it look somewhat dated. The best parts of the book are the extensive (139-page) discussion of antigens and the following section on antibodies. The discussion of antigens is made up of several interesting chapters, although some have a rather narrow perspective — for instance, Atassi exclusively describes his own work on defining antigenic epitopes on myoglobin, lysozyme and haemoglobin — while the section on antibodies is less detailed than that found in the other two books. Fearon's chapter on complement, however, is one of the best short descriptions of this topic that I have seen.

The section on cellular immunology lacks molecular information and may seem to overemphasize phenomenology, but it should be realized that most of the new discoveries are confirming and explaining the observations of traditional immunology. There are several chapters on methodology, with a particularly good section on electron microscopy by M.A. Gonda (though I was surprised there was only a brief description of flow cytofluorometry in the account of cell separation techniques). The balance of this book is rather different to the other texts, and it should therefore form a useful addition to library collections. □

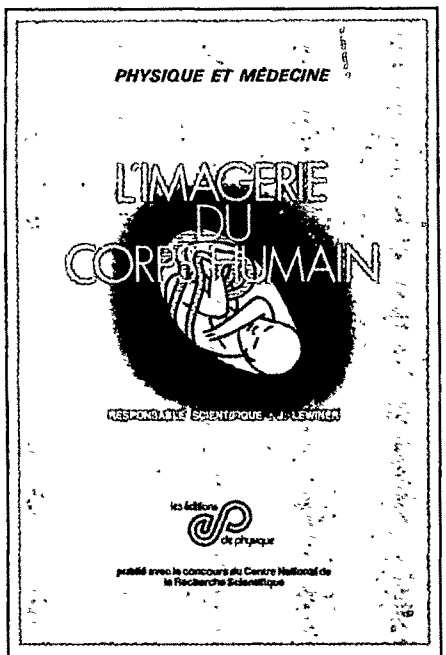
Tackling immunity

Brian Solomon

Essentials of Immunology.
By W.H. Hildemann.
Elsevier: 1984. Pp.146. Dfl. 60, $19.50.
Immunology: An Introduction.
By Ian R. Tizard.
Holt Saunders/Saunders College: 1984. Hbk £21, $31.95; pbk £7.95.

CHOOSING an original title for a book on basic immunology must nowadays be a thankless task. Unfortunately, *Essentials of Immunology* is too similar to the title of the well-established *Essential Immunology*, by Ivan Roitt, which is very different in style. In his preface the late Bill Hildemann suggested an alternative title of *Immunology in a Nutshell* and after reading the book I consider that this would have been much more appropriate.



The book's stated origins lie in a lecture course for medical and science students in the health sciences. This probably explains why the text resembles lecture notes and there is a heavy reliance on diagrams and complex tables. There are some paragraphs where there is a true flow of words, but usually facts are given in a jerky note form and the reader is soon referred to a table or figure for more information. With such a sparse text, generalizations have had to be made, inevitably so, but some are dangerously misleading. For example, the process of opsonization is not "complement-dependent" (for IgG) but IgM will only function as an opsonin when bound with $\overline{C1423}$; the Chediak-Higashi syndrome is chiefly notable for a deficiency of natural killer cells; and the propensity for immature B cells to be driven into tolerance by antigen (a strong teaching point) is not even mentioned.

Although the book concentrates on human immunology there are sudden switches to mouse or chicken experiments without warning. This occurs particularly in the "Overviews" at the end of each chapter. For example, the statement "that fetal and newborn mammals acquire passive immunity by placental passage of IgG and by assimilation of sIgM and sIgA from the colostrum" is bound to confuse medical students.

As a cellular immunologist, the author regards immunoglobulins as "ancillary to cell-mediated immune functions", and the sheer magic of the widely different biological functions of the various immunoglobulin classes is lost in a massive table. There is only one paragraph on ontogeny, while considering Bill Hildemann's enormous contribution to research on immunorecognition in invertebrates it was also disappointing to find only two short paragraphs on phylogeny with one unnecessary table and another with misleading information. In short, I found too little nut inside the nutshell.

In Ian Tizard's *Immunology: An Introduction*, the reader is struck at once by the confidence of the author's writing. Many grey areas of my knowledge were dispersed by this book. At the same time, newcomers to immunology will find all their basic requirements for getting to grips with the subject. The opening chapters follow a

Le médecin utilise de très nombreux outils nouveaux pour l'imagerie du corps humain, la thérapie, la surveillance et la régulation des paramètres psychologiques. L'interaction est donc de plus en plus forte entre médecins et physiciens.

Consacrés aux méthodes d'imagerie, les divers chapitres de cet ouvrage décrivent chacun une technique particulière et ont été écrits par des spécialistes. Ils concernent des domaines déjà bien utilisés tels que l'imagerie acoustique ou encore très futuristes comme la radiographie par diffusion nucléaire. On trouvera ainsi successivement les chapitres consacrés à :

— l'imagerie acoustique,
— l'imagerie micro-onde,
— la thermographie micro-onde,
— la tomographie d'émission,
— la radiographie par diffusion nucléaire.

conventional pathway through an early history of vaccines (Pasteur, Jenner) to antigens, major histocompatibility complex and phagocytes, followed by inflammation. Next, we suddenly leave cells for three chapters on antibodies before "tissues of the immune system" are approached. I feel a more logical order would have been to describe lymphoid organs and the differentiation of lymphocytes, then go on to discuss the induction of an immune response which would lead to a description of end products such as lymphokines and antibodies.

Among the antibodies much attention is given to allotypes, to the neglect of the sugars. Immunoglobulins are glycoproteins, and although the role of the oligosaccharides is still largely unknown they may help to dictate the various biological functions of the immunoglobulins. To indicate in a figure that IgE only has sugars bound to the C_H2 domain (like IgG) is incorrect as six oligosaccharides have been reported on three different C_H domains of IgE. There follows an excellent chapter on how to measure antigen–antibody reactions and antibody affinity, including a lucid section on antigen–antibody interaction with Fc receptors on cells.

As the author leads us into the jungle of immunoregulatory processes, he looks back at us over his shoulder to offer encouragement to "who has managed to follow so far"; we later graduate to a reader "who has managed to follow so far"! This is not because the book is difficult to understand, rather a sympathetic way of apologizing for the complexity of the subject. A stimulating chapter "Immunity at Body Surfaces" precedes another on vaccines which are dealt with very competently. However, absent here is an assessment of how successful vaccines have been in the improvements in public health from the turn of the century to the present day, and in the introduction of antibiotics. As vaccines are designed to induce memory cells and many properties of murine B memory cells have been described it was a pity not to include them.

The highlight and declared *modus operandi* of the book lies in the account of mechanisms of resistance to disease. This topic is bravely treated by separately dealing with bacteria, viruses, protozoa and helminths, an approach to a difficult subject which exposes many of the "nasties" practising immune evasion. A certain weakness in defining tropism with the microorganism's reliance on specific receptors on target cells can be excused as being "non-immunological", but I missed any account of the Duffy blood group – *Plasmodium vivax* story. Still, I like this book — it is how I would have described immunology myself and it has something in it for everyone. □

Brian Solomon is a Lecturer in the Department of Bacteriology at the University of Aberdeen.

Enzymology in the golden ages

Keith Tipton

Enzyme Structure and Mechanism, 2nd Edn.
By Alan Fersht.
W.H. Freeman: 1985. Pp.475. Hbk $24.95, £28.95; pbk £14.95.

ALTHOUGH an understanding of the behaviour of enzymes is essential for any full appreciation of the behaviour of living systems at the biochemical level, enzymology is too often regarded as being an esoteric and somewhat purposeless pursuit or a pedestrian and ossified technology. Anyone with such views should read this book. It is the author's contention that we are now entering a new golden age of enzymology, but this scholarly and enthusiastically written account suggests that such an age has existed for many years and will continue for many more.

A book of this size could not be expected to provide a comprehensive coverage of all aspects of enzymology and it is particularly strong in areas such as transient kinetics, enzyme mechanisms, and specificity and editing mechanisms, in which the author has been particularly active himself. However the generally well-chosen reference lists should allow readers to develop their knowledge in areas that receive less detailed coverage, for example steady-state kinetic analysis and the behaviour of metabolic pathways. The book is never dull and in controversial areas, such as the evolution of enzyme kinetic power, the author presents his own arguments cogently and convincingly.

Many will be familiar with the first edition of this work. In addition to the revision of much of the original material there are several new chapters, among them an account of enzyme stereospecificity, a topic which is often neglected in books of this type, and an excellent treatment of genetic engineering and enzymology. This latter chapter includes a particularly valuable consideration of the techniques of site-specific mutagenesis and their importance to the future development of the study of enzymes.

I have been recommending the first edition of this book to students, both undergraduate and graduate, since its publication in 1977. The appearance of this revised and expanded version is most welcome. I recommend it most highly as a stimulating and informative guide in which the ideas and principles behind our current understanding of enzymology are presented in such as way as to capture much of the excitement of the subject. □

Keith Tipton is Professor and Head of the Department of Biochemistry at Trinity College, Dublin.

Modern microbes

G.P.C. Salmond & R. Whittenbury

Biology of Microorganisms, 4th Edn.
By Thomas D. Brock, David W. Smith and Michael T. Madigan.
Prentice-Hall: 1984. Pp.847. Hbk $51.25, £46.70; pbk $26.95, £15.95.
Microbiology, 4th Edn.
By George A. Wistreich and Max D. Lechtman.
Macmillan, New York/Collier Macmillan, London: 1984. Pp.909. £40.*

"MAINLY old wine in new(ish) bottles" describes, perhaps unkindly, the two textbooks reviewed here. The first, a new edition of *Biology of Microorganisms,* has emerged with two new co-authors joining the originator of the enterprise, T.D. Brock. The product is a success, building on the previous tried and proved formula. Updating, particularly of the genetics and genetic engineering contributions is the major change from previous editions. Brock, the senior author, is widely regarded as the working general microbiologist's general microbiologist; consequently the content, style and depth of treatment, choice of illustrations, and table and diagram construction fit well with a general microbiologist's conception of what constitutes a good student textbook.

The microbe in its own right holds sway here, we are please to observe; for instance, accounts of structure, function, biochemistry and genetics, and of the microbe in relation to the environment, as a parasite and as a symbiont, all hang together in a way which draws the reader fairly painlessly into the complexity of modern microbiology. In all there are 19 chapters, with useful appendixes, a glossary and a reasonably comprehensive index. A particularly useful chapter is the last one, which describes representative prokaryotic groups and is, in effect, a series of compact essays conveying the essential biology and the unique attributes of each group. This book compares well with the other leaders in the field and is a strong contender for adoption by undergraduates reading courses in which microbiology is a significant component.

Wistreich and Lechtman's *Microbiology,* also in its fourth edition, represents a brave but, in our eyes, unsuccessful attempt to produce a modern balanced textbook of general microbiology. The book is organized into eight parts; the relative emphasis on the constituent subjects, however, is very uneven. For example Part II is designed to inform on the wide topics of growth, cultivation, metabolism and genetics. This covers only three chapters (6, 7 and 8) accounting for about 75 pages. On the other hand, medical microbiology and immunology start at Chapter 19 and go through to the end of Chapter 28, taking approximately half of the book. The rest of the book covers various matters, including microbial ecology, industrial microbiology, cell structure and function, and virology.

Perhaps worse than the imbalance in treatment is that the text is superficial in terms of content. Indeed, many parts of the book are likely to be totally misleading, either due to bad grammar or errors of fact. Chapter 8 on microbial genetics is a particularly illuminating example on both counts. It is littered with confusing information, contains mistakes and is badly out of date (for instance, no mention is made of yeast genetics). The poor balance of the book shows up even here where only four pages are dedicated to the topic of genetic manipulation — probably *the* cornerstone technique of modern biology!

There are some good points to the book, however. On the whole, it is easy to read, there is a wealth of diagrams in both black-and-white and colour, and the photographs are of a high standard. Each chapter begins by listing the things that you should know, and ends (in a form suspiciously like a list of examination questions) with a summary of the salient points plus questions and suggestions for further reading. Our impression, then, is that although this is an excellent microbiology "picture book" the very heavy emphasis on things medical severely perturbs its balance. □

G.P.C. Salmond is a Lecturer and R. Whittenbury a Professor in the Department of Biological Sciences at the University of Warwick.

Bodily functions

Ole H. Petersen

Anatomy and Physiology, Vol.1, 2nd Edn.
By Edwin B. Steen and Ashley Montagu.
Barnes and Noble/Harper & Row: 1984. Pp.406. Pbk $6.95, £4.95.
Essentials of Human Anatomy and Physiology.
By Elaine Nicpon Marieb.
Addison-Wesley: 1984. Pp.355. Pbk $17.95, £18.
Physiology of the Human Body, 6th Edn.
By Arthur C. Guyton.
Holt Saunders/Holt, Rinehart & Winston: 1984. Pp.691. Hbk £32.50, $37.95; pbk £8.50.
Essentials of Physiology, 2nd Edn.
By J.F. Lamb, C.G. Ingram, I.A. Johnston and R.M. Pitman.
Blackwell Scientific/C.V. Mosby: 1984. Pp.465. Hbk $18.95; pbk £12.50.

IN THE preface to Guyton's *Physiology of the Human Body* it is correctly stated that " . . . physiology continues in a dynamic stage of discovery with new knowledge of basic physiological concepts generated each day". Unfortunately, these new concepts do not figure prominently in any of the four textbooks reviewed here, and this is clearly due to the practice admitted in the preface to Lamb *et al.'s Essentials of Physiology*: "The reference list included is generally that which we found useful and usually consists of other secondary references, i.e. larger texts, monographs, etc". In other words, authors of physiology textbooks mostly get their information from other textbooks of physiology.

Steen and Montagu's *Anatomy and Physiology* is not a real textbook, but more a compendium of basic anatomical and physiological facts presented in a small-format paperback. It is in two volumes, but at present only Vol. 1 covering blood, circulation and the muscular and digestive systems is available. The index is not bad and when the companion volume appears this work could well be useful for last-minute revision purposes.

Essentials of Human Anatomy and Physiology is designed to meet the needs of students in the allied health fields and as such is in direct competition with the more attractive *Human Anatomy and Physiology* by Solomon and Davis which was reviewed last year (*Nature* **308**, 129; 1984). The anatomy sections are better than those dealing with physiology, in which basic errors can be found; for example the figure illustrating exchange of oxygen and carbon dioxide between tissues and capillaries indicates wrongly that the red cells are only concerned with oxygen and that all carbon dioxide is transported in the plasma.

Guyton's *Physiology of the Human Body*, now appearing in its sixth edition, is a thoroughly professional book with particularly good black-and-red diagrams and a text which is easy to read. It covers the same ground as *Textbook of Medical Physiology* by the same author, but with less emphasis on medical aspects. Each chapter starts with a brief overview summarizing the most important points and ends with a short list of questions and references. However, in spite of the addition of some new references, the book could essentially have been written 20 years ago. Key topics such as control of the heart, nerve action potential and transport in the kidney tubules are discussed without any reference to the important results obtained with the new methodologies of recent years. This can make the presentation unnecessarily complicated, when, for example, the electric action potential is explained in terms of ill-defined permeability changes instead of through opening and closure of specific ion channel molecules in the plasma membrane.

Unfortunately, Lamb *et al.'s Essentials of Physiology*, which is aimed at medical,

dental and science students, is only marginally better than Guyton's book in explaining the basic bioelectric phenomena which are central to so many physiological processes. Indeed one crucial figure (2.3 on p.29) is both confusing and incorrect by mixing up permeability and conductance, and the muddle is complete when megaohm is used as the unit! *Essentials of Physiology* is much more up to date than Guyton's textbook, but for a second edition it contains an astonishing number of omissions, mistakes and inconsistencies. Lundsgaard, my teacher as an undergraduate student in Copenhagen, often expressed the view that those unable to describe the effects of stimulating the sympathetic or parasympathetic nerves to the heart should not expect to survive his examination, but a present-day student relying on *Essentials of Physiology* would be in trouble as the positive inotropic action of sympathetic nerve stimulation is not mentioned explicitly in the section on the regulation of cardiac output. How marvellous if this and the other textbooks were to explain that this inotropic effect is due, at least in part, to an increased flow of calcium ions into the myocardial cells resulting from activation of selective calcium channels in the plasma membrane by the elevated intracellular cyclic adenosine monophosphate concentration (Reuter's excellent review of the process — *Nature* **301**, 569–574; 1983 — is recommended to all those writing a physiology textbook).

Lamb's book nevertheless has many positive features, such as the introductory ideas in the first chapter with its instructive and amusing figures, the excellent description of the mechanics of muscle contraction and the useful appendix on units and formulae. But one cannot help feeling that the authors have failed to read carefully and critically the whole text before sending it to the printers; thus the hormone cholecystokinin is variously referred to as CPZ, pancreozymin, CCK-PK, CCK and CCK-PZ, cyclic adenosine monophosphate is introduced as cyclic AMP without explaining the abbreviation and some of the diagrams (for example that of the exocrine pancreas on p. 155) are lacking in precision and likely to be misunderstood by many students.

None of these four textbooks provide good examples of how physiological data obtained at the cellular level can help us to understand important disease symptoms. The osmotic diuresis seen in diabetes mellitus, for example, can be simply and logically explained on the basis of the known transport characteristics of the different segments of the nephron, but none of the authors even mention the term osmotic diuresis. It is indeed a pity that many such good opportunities for helping students to use physiological reasoning have been missed. □

Ole H. Petersen is George Holt Professor of Physiology at the University of Liverpool.

The developing side of biology

Mary Bownes

Developmental Biology, 2nd Edn.
By Leon W. Browder.
Holt Saunders/Holt, Rinehart & Winston: 1984. Pp.748. Hbk £32.95, $37.95; pbk £17.95.
Developmental Control in Animals and Plants, 2nd Edn.
Edited by C.F. Graham and P.F. Wareing.
Blackwell Scientific: 1984. Pp.519. Hbk $37; pbk £18.50.
Genetics and Development.
By James H. Sang.
Longman: 1984. Pp.398. Pbk £13.95, $25.

THE rapid advances in our understanding of the genetic control of development and the molecular basis of developmental mechanisms make this an exciting period for students of developmental biology. All three of the books reviewed here cover both plants and animals, which is a major step forward, although in each case the space devoted to plant development is rather less than that devoted to animals.

Browder's *Developmental Biology*, now in its second edition, is the most basic text of the three and is extremely well written, up to date and enjoyable to read. The introduction provides a historical look at the topic, sets the context for the following five sections and briefly describes the main aspects of animal development. The subsequent sections each contain two to four chapters, advanced topics being dealt with in essays set aside from the main body of text. "The Cell in Development" (Section 2) covers not only the basic concepts of determination and differentiation but also chromatin and its structure, RNA and protein synthesis and the mechanisms of regulating gene expression, both transcriptional and post-transcriptional, and finally the cytoskeleton. This should give students a good idea of where many of the advances are being made, and the author provides sufficient background in molecular biology and genetics to make the section genuinely valuable rather than merely superficial.

There are detailed analyses of spermatogenesis, oogenesis and plant gametogenesis, followed by chapters on fertilization and "becoming multicellular". There is then a return from the more cellular experiments to the molecular, and the role of gene expression during the initiation of development is well described. The final section describes the processes of forming a multilayered embryo, and generating the wide range of cell types organized such that they create a functional organism. Throughout, the experimental basis of the subject is emphasized and well explained, and the text is beautifully illustrated with many clear and informative photographs and diagrams. This is a book that all students interested in development will find very rewarding.

The other two books are aimed at advanced undergraduates and, to some extent, at postgraduates and research workers too. Graham and Wareing's *Developmental Control in Animals and Plants*, also in its second edition, is a multi-author effort. The disadvantages of such volumes are well-known — lack of continuity of style and approach — yet, of course, in compensation each person is an expert in a given area. My expectation was that the book would thus be well up to date, but although the chapters are generally well written and interesting, only the final contribution by Woodland and Old ("Gene Expression in Animal Development") includes the kind of very recent experimental analysis one would hope for. This is fortunate since this area is moving especially fast.

The six parts cover developmental processes, the origin and maintenance of cell heterogeneity, cell communication, pattern and form, hormones and the molecular biology of development. One of the main aims of the authors was to present both plant and animal development at an advanced level. Several chapters in Part 5, "Hormones in Development", fall rather short of this. In the plant chapters there is no mention of the current controversy over plant growth factors, the authors taking a very classical approach to the topic which is perhaps no longer appropriate, while the chapter on hormones in animal development is somewhat narrow, concentrating rather too much on steroid hormones and the chick oestrogen and *Xenopus* vitellogenin systems.

Sang's *Genetics and Development*, intended for those interested in the genetic mechanisms controlling development, fills a long-standing gap in the textbook market. It is a stimulating and detailed account of the current state of a rapidly moving area of research, aiming to provide the basis for students to be able to follow research papers. This it certainly does.

All of the six sections are heavily biased towards *Drosophila*, but this does not prevent the author meeting his objectives. The section on genome organization covers details of sequence organization and chromatin structure, polytene chromosomes and various models for regulating gene expression. Included under "Mutations" are definitions of what is meant by dominance, dosage compensation and complementation, analysis of complex loci and discussion of how the study of mutations enabled the structure of genes to be unravelled. Hormonally controlled and developmentally regulated genes are described and, finally, mutations which cause lethality at various developmental stages are analysed. In a section on tissue-determination and regeneration the

author concentrates on the production of mosaics and chimaeras to analyse these problems. A special account is devoted to the very topical area of determination mutants where the homoeotic mutants are investigated along with the problems of sex determination; this is particularly useful as many of the molecular studies on these systems demand an understanding of large amounts of background genetics which are rarely documented in such a complete form that students can see how progress has been possible and begin to tackle reading the research papers. The final section on future developments concentrates on cellular systems, a personal view of which areas of research are likely to be fruitful, and the book ends with an analysis of problems still to be solved.

In this book Sang has succeeded in bringing together the classical genetic approach of using mutations to study development with the more recent molecular techniques. I'm sure it will be of great use to students of both genetics and developmental biology. □

Mary Bownes is a Lecturer in the Department of Molecular Biology at the University of Edinburgh.

Nervous connections

Julian Lewis

Development of Nerve Cells and Their Connections.
By W.G. Hopkins and M.C. Brown.
Cambridge University Press: 1984.
Pp.137. Hbk £16, $29.95; pbk £6.95, $13.95.

Principles of Neural Development.
By Dale Purves and Jeff W. Lichtman.
Sinauer/Blackwell Scientific: 1985.
Pp.433. $32.50, £29.50.

From Neuron to Brain, 2nd Edn.
By Stephen W. Kuffler, John G. Nicholls and A. Robert Martin.
Sinauer/Blackwell Scientific: 1984.
Pp.651. Hbk $30; pbk £14.80.

THE development of the nervous system is not yet one of those subjects where a set of fundamental principles emerges neatly from a series of crucial experiments. Perhaps it will be one day: therein lies the challenge. To optimists, the published literature seems like the jumbled pieces of a giant jigsaw puzzle: find the right arrangement, and a beautifully coherent picture will emerge. Others, with less faith in universal principles, may perceive only a rambling mass of natural history anecdotes, fascinating to relate, but with no more logical unity than the Arabian Nights entertainments.

In *Development of Nerve Cells and Their Connections*, Hopkins and Brown adopt a sober and businesslike approach: their short, well-referenced and very reasonably-priced book offers a terse, dispassionate review of what is known about neural development, beginning with the genesis of neurones in the embryo and ending with plasticity and regeneration in the adult. They do not attempt to dramatize the data, and the reader is often left to supply his own emphases. For this reason, and because the presentation is rather condensed and bare of practical details or pictures of the numerous experimental systems discussed, the book, and especially its first half, may be hard going for newcomers to the subject. I found the second half, dealing with the modification of neural connections, the more valuable. As one might expect from these authors, it includes a particularly lucid discussion of synapse elimination and of nerve sprouting. And it is the only one of the books under review that has the courage to tackle head-on, in a few useful and well-organized pages, the problem of learning and memory; the other two venture only a sideways glance at this central enigma.

Purves and Lichtman's larger and more ambitious book, *Principles of Neural Development*, is a masterpiece: comprehensive but not stodgy, clear, accurate, elegantly written, beautifully and copiously illustrated. Even if you don't like words, you will be seduced by the pictures. While it does not offer any revolutionary new synthesis, the book succeeds, better than any previous text on the subject, in the very difficult task of weaving the inchoate mass of data on neural development into a single coherent narrative. Despite the 47 pages of references, and a scholarly care in assigning credit and priorities, Purves and Lichtman avoid the dismal blight that often afflicts *Annual Reviews*, where so many experiments are squeezed into so small a space that no life is left in them. Key experiments are made vivid and concrete by means of figures displaying the methods, materials and observations, reproduced as far as possible from the original papers.

The historical antecedents of modern work are particularly well portrayed. I enjoyed especially the short (one page) biographies of scientists, past and present, who have played major parts in the story. These sketches provide more than the usual bland catalogue of dates and discoveries, managing, in a few paragraphs, not only to explain how and why the scientific achievements were important, but also to bring the characters to life. Purves and Lichtman also have an excellent way with unresolved scientific conflicts: they set out the arguments fairly and squarely, and then tactfully and undogmatically offer their own judgement. As from all the best books, one learns about a great deal more than the title promises, from the principles of Nomarski interference contrast to the discomforts of wearing a reversing pseudophone.

From Neuron to Brain, by Kuffler, Nicholls and Martin, is the second edition of a classic. The first edition was for me and many others a memorable and engrossing introduction to the cellular basis of neurophysiology. It succeeded in large measure by sticking to the excellent principle that it is better — and more fun — to learn ten things well than a hundred things superficially. The authors focused on topics that they knew intimately, and conveyed their fascination with them.

The new edition retains the structure and much of the text of the old, but is enlarged by about 30%. It opens, as before, with a discussion of how neurones represent information about the visual world, updated where appropriate but as good as ever. Spurred on and sustained by the sense that the workings of neurones are the key to the higher functions of the brain, the reader is then taken through the more arduous analysis of the electrical properties of neurones and of synaptic transmission.

Konrad Lorenz with his geese. The picture is reproduced from one of the short biographies in Principles of Neural Development.

The revision here has been more drastic, making the account more rigorous, more complete and less readable for beginners. New topics such as patch clamp recording of currents through single channels are covered clearly and concisely, though sometimes without as much adjustment of the balance of emphasis as they deserve. One does not get the sense that any of the new techniques and discoveries of the past eight years have yielded any radical changes in our perception of neurones or the nervous system, or made any significant part of the material in the first edition obsolete. Is it really true, as stated in the "Concluding Remarks", that "we still do not understand the basic mechanisms that underlie changes in membrane permeability and active transport"?

Subsequent chapters include, together with the old material, many good new things, from sensitization in *Aplysia* to the role of the basal lamina in synapse formation, and a whole new chapter on the control of movement. This is still an outstanding book. □

Julian Lewis is a Lecturer in the Department of Anatomy at King's College, University of London.

Textbook supplement — prices

Where possible both dollar prices in the United States and sterling prices in Britain are given in the bibliographical details for each book. Export prices will generally be higher. If a dollar or sterling price is not cited, the book is not available in one of the two countries. However readers should check both price and availability of books before ordering.

New Titles from Chapman and Hall

Physiological Ecology of American Plant Communities

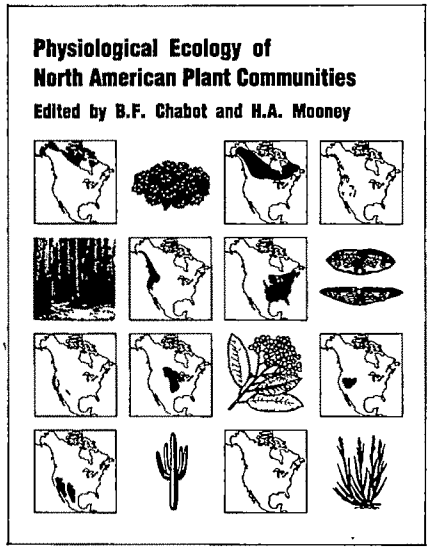
Edited by
B F CHABOT and H MOONEY

The enormous diversity of the plant types which occur in North America provide the material for the development of a comprehensive picture of the mechanisms which plants have evolved to cope with some of the most varied and hostile habitats on earth. This unique book is a series of original, integrated essays which provide not only a review of current knowledge, but also demonstrate the power of the physiological ecology approach in solving basic problems relating to adaptation and distribution.

April 1985 246 x 189 368 pp
Hardback 0 412 23240 5 £32.50

Seventh Edition

Selective Toxicity



The physico-chemical basis of therapy

A ALBERT

This distinguished and popular book, now in its extensively revised 7th edition, describes the way in which drugs and agricultural agents work at the molecular level; particularly how they are able to affect certain cells without harming others.

From reviews of the Sixth Edition:
'Professor Albert's breadth of knowledge and 'insight' for the interactions between chemicals and specific forms of life come over very forcibly. I recommend this book to all students and research workers in the biological sciences.'

January 1985 764 pp
Hardback 0 412 26010 7 £40.00
Paperback 0 412 26020 4 £19 75

Chemistry and Biochemistry of the Amino Acids

Edited by G C BARRETT

In this comprehensive monograph on the amino acids every aspect of their chemistry and biochemistry is dealt with in depth, making this an essential reference work. The treatment is thoroughly up-to-date summarizing the enormous advances in our knowledge of the properties and functions of amino acids which have taken place in the last two decades

January 1985 694 pp
Hardback 0 412 23410 6 £49.50

Chemistry of Hydrocarbon Combustion

D J HUCKNALL

This book reviews in detail our current knowledge of the chemistry of hydrocarbon combustion. No other book contains so much up-to-date information on all the reactions of relevance to hydrocarbon combustion and presents critically current views on hydrocarbon combustion under a wide range of conditions.

April 1985 424 pp
Hardback 0 412 26110 3 £39.50

Chemical Bonding and Spectroscopy in Mineral Chemistry

Edited by F J BERRY and D J VAUGHAN

This text provides an up-to-date introduction to the concepts and techniques involved in mineral spectroscopy and bonding studies. The eight chapters, each written by an expert in the field, cover quantum mechanical models in mineralogy, X-ray spectroscopy, electronic absorption spectroscopy, luminescence studies, Mossbauer spectroscopy, ESR and NMR, studies of opaque minerals and surface studies in mineralogy

March 1985 348 pp illus
Hardback 0 412 25270 8 £35.00

Introduction to Corrosion and Protection of Metals

G WRANGLEN

This is a systematic, balanced review of metallic corrosion and its prevention. It is intended as a introductory course for engineering students It is also a useful reference book for engineers working with metal construction materials. A comprehensive treatment of electrochemistry, corrosion kinetics, the nature of kinetics and the influence of the environment is given. Together with various methods of corrosion prevention

Macmillan Paperback 464 pp 297 x 210 mm
ISBN 0 333 36682 4 **November 1984 £65.00**

The most comprehensive single source of up-to-date authoritative information on today's biotechnology world.

Now *The International Biotechnology Directory* gives you even more data to help you keep right up to date with important developments in this fast moving industry.

- ★ Over 1200 NEW entries
- ★ **NEW full entries** for Australasia and Brazil, plus more information on UK, USA, European countries and Japan
- ★ Over 950 products and services in Buyers' Guide.
- ★ **NEW journals** More than 100 updates, including changes of prices and addresses, as well as details of new journals and newsletters.
- ★ Over 4000 entries for commercial and non-commercial organizations.
- ★ **NEW** comprehensive alphabetical index to directory's unique Buyers' Guide to products, research and services, fully cross referenced to speed access to data.

Moreover, the directory covers both the old established biotechnologies — brewing, food processing, pharmaceuticals and waste treatment — and the new advancing genetic engineering technologies.

Worldwide coverage

The directory covers **all** the countries where the biotechnology industry is most active today. Australia, Austria, Belgium, Brazil, Canada, Denmark, Finland, France, Germany, Greece, Ireland, Israel, Italy, Japan, Netherlands, New Zealand, Norway, Portugal, Spain, Sweden, Switzerland, United Kingdom and the United States

Comprehensive range of hard information allows you to identify and compare accurately:

- International organizations
- Government agencies and programmes
- Information sources
- Societies and associations
- Non-commercial organizations
- Commercial companies active in biotechnology

Authoritative author

Dr. Jim Coombs is a consultant for the EEC on the Biomass for Energy Programme, and the EEC's Forecasting and Assessment in Science and Technology (FAST) Programme for Biotechnology. He is editor of *Biomass* and Secretary of BABA

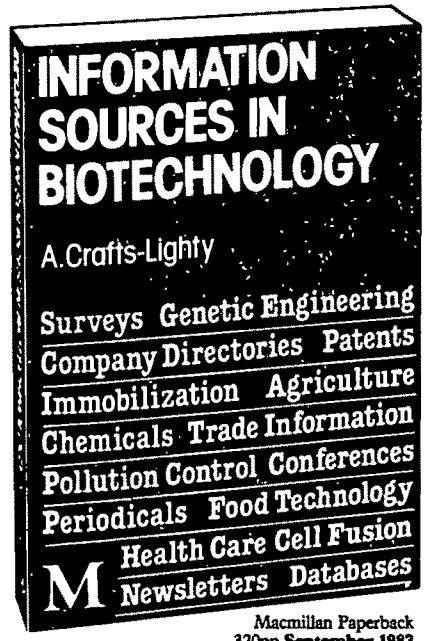
Without the directory you will not be completely up-to-date and not entirely competitive. Take a copy on FREE APPROVAL and judge for yourself.

Send no money now — examine on FREE APPROVAL

Take *The International Biotechnology Directory 1985* on free approval for 30 days without commitment to purchase. Decide to keep the directory, then simply pay the invoice accompanying the book. If you are not convinced that it is a sound investment at £65.00, just return the book in good condition within 30 days with the invoice. Complete the order form below **now** to ensure prompt delivery.

Your guide to the selection of cost-effective biotechnology information sources

Evaluates and assesses the whole range of information sources available.



- covers databases and directories
- covers technical and commercial literature.
- covers difficult and hard to trace sources.
- includes over 20 at-a-glance evaluation tables.
- provides an Index of publishers and their addresses.

Dr. Crafts-Lighty, Information Manager for Celltech Ltd., systematically and critically reviews

★ books ★ conferences ★ trade periodicals ★ research periodicals ★ computer databases ★ patents ★ market surveys ★ directories ★ organisations ★ secondary sources.

With her specialist guidance you can save time and money by selecting the really cost-effective sources of information.

Order your copy **NOW.**

Macmillan Paperback
320pp **September 1983**
ISBN 0 333 36178 4 **£40.00**

AVAILABLE ON 30 DAYS FREE APPROVAL SEND NO MONEY NOW

An invaluable guide to business and commercial as well as technical biotechnology information sources for:

- Businessmen in all industries affected by biotechnology.
- Researchers, librarians and information officers.
- Investment analysts and investors who want to find out about the biotechnology industry.
- Academic researchers who need to know and evaluate biotechnology information sources.
- Librarians who need an evaluation of the literature and of library practice in this important new field.

Demonstration by monoclonal antibodies that carbohydrate structures of glycoproteins and glycolipids are onco-developmental antigens

Ten Feizi

Applied Immunochemistry Research Group, Division of Communicable Diseases, Clinical Research Centre, Watford Road, Harrow, Middlesex HA1 3UJ, UK

The hope that hybridoma antibodies would reveal unique cell surface antigens during embryogenesis, differentiation and oncogenesis has been replaced by the realization that such antigens are mainly carbohydrate structures of glycoproteins and glycolipids occurring in many cell types. These findings either may reflect limitations in the methods of selection of hybridoma antibodies or may point to important roles for the diverse carbohydrate structures as receptors for regulators of cell growth and differentiation.

MONOCLONAL antibodies of desired specificity can be produced by the hybridoma technique[1], providing a rapid means of detecting antigens which change during cellular differentiation and maturation (differentiation antigens)[2]. The feasibility of this approach was apparent when a hybridoma antibody of this type was produced incidentally, following immunization of a rat with mouse splenocytes[3]. Serological studies showed that this antibody (M1:22:25:8) which recognizes an antigen with stage-specific expression in the early mouse embryo, becoming restricted only to certain cells in the adult mouse, has Forssman-type specificity[3]. Subsequent biochemical studies[4] confirmed that the antibody recognizes the carbohydrate sequence of the Forssman antigen (structure 20, Table 2), found commonly on glycolipids[5] and occurring also on glycoproteins[6].

Developmental biologists were among the first to use hybridomas to generate 'tailor-made' antibodies to surface antigens of embryonic cells[7]. The antigens, however, seemed elusive; they could not be identified readily by the usual techniques of immune precipitation and polyacrylamide gel electrophoresis. Several of them, including some oncofetal (tumour-associated) antigens, have been shown subsequently to be either carbohydrate sequences on high relative molecular mass (M_r) glycoproteins (or polysaccharides) which cannot be radioiodinated or metabolically labelled with ^{35}S-methionine to sufficiently high specific activities and do not penetrate readily the polyacrylamide gels[8], or they are associated with glycolipids[9]. I review here antigens that have been singled out by monoclonal antibodies as differentiation or tumour-associated antigens and have been shown later to be specific carbohydrate sequences. I discuss their possible roles and conclude by citing some examples of carbohydrate sequences to which biological roles have been assigned without immunological techniques.

Natural monoclonal antibodies

Developmentally regulated antigens were first identified as carbohydrate structures by experiments with certain natural monoclonal antibodies, anti-I and anti-i, occurring in the sera of patients with an autoimmune haemolytic disorder (reviewed in ref. 10) and recognizing two developmentally regulated antigens, I and i, of human erythrocytes. The i antigen is a prominent erythrocyte antigen of the human fetus, diminishing after birth and during the first year of life, while the related antigen, I, increases to the adult concentration[11]. These antigens are now known to be carbohydrate structures on glycoproteins and glycolipids of erythrocytes and other cell types[12-14], consisting of repeating units of *N*-acetyllactosamine (Galβ1→4GlcNAc). This disaccharide sequence is also termed the Type 2 blood group chain[15] or backbone structure[16], to distinguish it from the isomer Galβ1→3GlcNAc (Type 1); both sequences may serve as precursor chains, converted into blood group antigens by further glycosylations. Unbranched oligosaccharides of three or four repeating *N*-acetyllactosamine units joined to each other by a β1→3 linkage (see structure 1, Table 1) express the i antigen[17,18], whereas the corresponding branched structures, formed by β1→6 linkage of *N*-acetyllactosamine units to internal galactose residues of the repeating sequence (as in structure 2, Table 1), express the I antigen[19,20]. During the first year of life, there may be an increased activity of a glycosyltransferase (branching enzyme)[21,101] which transfers *N*-acetylglucosamine via a 1→6 linkage to a previously formed linear chain.

Because undifferentiated cells of the early mouse embryo contain surface glycoproteins with poly-*N*-acetyllactosamine sequences[22], we used monoclonal anti-I and anti-i antibodies against different epitopes on the branched and linear chains to search for such structures both in cells of the early mouse embryo and in cultured embryonal carcinoma cells throughout differentiation and observed that there is a stage-specific expression of the antigens associated with the branched and the linear structures[23,24]. The 'branched' antigen was found on mouse embryos from the zygote stage onwards and the 'linear' antigen became detectable at a later stage (5 days after fertilization) in the first differentiated cells, that is, those of the primitive endoderm. This order of appearance of the branched and linear structures contrasts with that in the human erythrocyte membranes, but the branched structures in the early mouse embryo may be formed by the glycosyltransferases of maternal origin in the oocyte; the linear structures, appearing at onset of differentiation, may represent the first fetal products in this series.

Hybridoma-defined carbohydrate antigens

Following observations on the changing expression of the I and i antigens in the early mouse embryo, it was thought (P. W. Andrews and T. F., unpublished) that the hybridoma antibody anti-SSEA-1 against an antigen appearing at the 8-cell-stage of the mouse embryo[7] might be directed against a carbohydrate structure related to the Ii antigen system. We therefore examined the reactivity of anti-SSEA-1 with a variety of glycoproteins known to express the I and i antigens; we found that anti-SSEA-1 reacts with the intestinal glycoproteins (meconium) of the human fetus[25] and used oligosaccharides to inhibit the binding of the anti-embryo antibody, measured by radioimmunoassay. We established[25,26] that anti-SSEA-1 recognizes α1→3 fucosylated *N*-acetyllactosamine (3-fucosyl-*N*-acetyllactosamine; structure 4, Table 1) and deduced that during mouse development, backbone structures of I-type can be converted into SSEA-1 active structures by α1→3 fucosylation[25]. The 3-fucosyl-*N*-acetyllactosamine sequence is not unique to the mouse embryo; it was first discovered in human ovarian cyst glycoproteins[27], later found among glycolipids of human adenocarcinomas[28] and also in serum glycoproteins and oligosaccharides of human milk

and urine (reviewed in refs 9 and 29). In contrast, this structure in adult mouse occurs only at restricted sites[7]. A second fucose residue joined by $\alpha 1 \rightarrow 2$ linkage to the galactose residue (see structure 6, Table 1) masked completely the expression of the SSEA-1 determinant[25,29], suggesting that the sequential addition (or deletion) of monosaccharides might be one mechanism for the appearance, disappearance and reappearance of antigens during stages of embryogenesis and differentiation[25,30]. The specificity of anti-SSEA-1 was investigated also by structural studies of human erythrocyte glycolipids which contain the SSEA-1 determinant[31-33] and human gastrointestinal glycolipids[34]; there is now agreement that this determinant consists of the 3-fucosyl-*N*-acetyllactosamine structure. An antibody, D_1 56-22, raised against a colon cancer cell line, also recognizes this structure[34]. Furthermore, two or three repeats of this sequence have been detected in some human adenocarcinomas[9].

A variety of monoclonal antibody-defined differentiation antigens of murine and human haematopoeitic or epithelial cells and certain human oncofetal antigens are also carbohydrates, expressed on Type 1 as well as Type 2 backbone sequences or on their additionally glycosylated analogues and may be carried both on glycoproteins and glycolipids (Table 1). Other oncofetal antigens are expressed on carbohydrate chains of the lactosyl-, ganglio- and the globo-series glycolipids (Table 2). Among the structures in Table 1 are those of the major blood group antigens A, B, H, Le^a and Le^b, included first to show their relationship to the antigenic determinants recognized by the anti-mouse embryo antibody anti-SSEA-1 and the anti-human myeloid cell antibodies VEP8 and VEP9, MY-1 and VIM-D5, the anti-human teratocarcinoma antibody FC 10.2, the anti-human adenocarcinoma/adenoma antibodies 19-9, C14, F3 and D_1 56-22, and the anti-milk fat globule antibodies M39 and M18. Second, a number of the monoclonal antibodies MH2, NS-10 and the E1 and the CO series which were thought initially to recognize human adenocarcinoma-associated antigens, were later shown to be directed against the blood group antigens ALe^b/Le^y, B, Le^a or Le^b. Presumably, the tumour cells used as immunogens were derived from individuals with the various blood-group genes.

Carbohydrate antigens have different patterns of expression in various animal species. For example, structure 4 (Table 1) recognized by anti-SSEA-1 is a distinctive antigen of granulocytes among human peripheral blood cells[29,35], but is not expressed on murine, rat, rabbit or porcine granulocytes[36]. Moreover, a carbohydrate antigen may be a normal component in one cell type but a tumour-associated antigen in another. Structure 3 (Table 1), recognized by the monoclonal anti-I antibody Ma, is one such example; this antigen is a normal component of human erythrocytes but is a tumour-associated antigen in gastric adenocarcinomas of individuals who secrete the blood group ABH antigens[37,38]. The biochemical basis of the latter observation may be as follows: the I(Ma) determinant, consisting of the branchpoint sequence $Gal\beta 1 \rightarrow 4GlcNAc\beta 1 \rightarrow 6$ (see Table 1), occurs abundantly among the oligosaccharides of gastric mucosal glycoproteins and secreted gastric mucins[37,38].

Table 1 Differentiation antigens first detected by monoclonal antibodies and identified subsequently as carbohydrate structures based on Type 1 or Type 2 blood group chains

	Structure	Designation of antigen	Cell association
1	$Gal\beta 1 \rightarrow 4GlcNAc\beta 1 \rightarrow 3(Gal\beta 1 \rightarrow 4GlcNAc\beta 1 \rightarrow 3) \geq 2$	i	Fetal erythrocytes, human[17,18], primary endoderm, mouse[23]
2	$Gal\beta 1 \rightarrow 4GlcNAc\beta 1 \rightarrow {}^{6}_{3}Gal\beta 1 \rightarrow 4GlcNAc\beta 1$	I	Adult erythrocytes, human[19]; preimplantation embryos, mouse[23,24]
3	$Gal\beta 1 \rightarrow 4GlcNAc\beta 1 \rightarrow {}^{6}Gal/GalNAc$	I(Ma)	Adult erythrocytes, human[81]; gastric mucosa, non-secretors; gastric adenocarcinomas, secretors[37,38,40]
		M18, M39	Breast epithelium, human[82]
4	$Gal\beta 1 \rightarrow 4GlcNAc$ (↑1,3 $Fuc\alpha$)	SSEA-1 VEP8 and VEP9, Myl, VIM-D5 etc. $D_1$56-22 (X hapten, Le^x)	8-Cell stage mouse embryo[25,26,33] Myeloid cells, human[29,35,83] Colorectal cancer, human[34]
5	$Gal\beta 1 \rightarrow 4GlcNAc$ (↑1,2 $Fuc\alpha$)	TRA-1-85 (blood group H)	Human cell lines*
6	$Gal\beta 1 \rightarrow 4GlcNAc$ (↑1,2 $Fuc\alpha$; ↑1,3 $Fuc\alpha$)	C14 F3 AH6 (Y hapten, Le^y)	Colonic adenocarcinoma, human[84] Lung adenocarcinoma, human[85] Gastric cancer, human[86] Embryonal carcinoma cells, human and mouse[87]
7	$GalNAc\alpha 1 \rightarrow 3Gal\beta 1 \rightarrow 4/3GlcNAc$ (↑1,2 $Fuc\alpha$)	TL5 (blood group A)	EGF receptor of A431 cells[55]
8	$Gal\alpha 1 \rightarrow 3Gal\beta 1 \rightarrow 4GlcNAc$ (↑1,2 $Fuc\alpha$)	E_1 series (blood group B)	Pancreatic cancer[34]
9	$Gal\beta 1 \rightarrow 3GlcNAc\beta 1 \rightarrow 3Gal\beta 1 \rightarrow 4Glc/GlcNAc$	FC10.2	Embryonal carcinoma cells, human[88]; gastric mucosa, non-secretors; gastric adenocarcinoma, secretors[40]
10	$Gal\beta 1 \rightarrow 3GlcNAc$ (↑1,4 $Fuc\alpha$)	CO-514 (blood group Le^a)	Adenocarcinomas, human[89]
11	$Gal\beta 1 \rightarrow 3GlcNAc$ (↑1,2 $Fuc\alpha$; ↑1,4 $Fuc\alpha$)	NS-10 CO-43 (blood group Le^b)	Adenocarcinomas, human[89]
12	$GalNAc\alpha 1 \rightarrow 3Gal\beta 1 \rightarrow 3/4GlcNAc$ (↑1,2 $Fuc\alpha$; ↑1,3/4 $Fuc\alpha$)	G49 MH2 (blood group ALe^b/Le^y)	EGF receptor of A431 cells[90] Colonic adenocarcinoma, human (cited in ref 53)
13	$Gal\beta 1 \rightarrow 3GlcNAc$ (↑2,3 $NeuAc\alpha$; ↑1,4 $Fuc\alpha$)	19 9 (sialyl Le^a)	Colon cancer, human[39]; normal pancreatic ducts[34], normal gastric mucins, non-secretors; gastric cancer mucins, secretors[40], human seminal fluid proteins[41]

* J. K. Picard, P. Goodfellow, P. W. Andrews, G. L. Daniels, K. Uemura & T. Feizi, unpublished observations.

In the majority of the 'secretor' population (whose glycoprotein secretions express the blood group A, B or H antigens of their erythrocytes) the antigenicity of this structure is normally masked by the blood group A, B or H monosaccharides. On the other hand, this antigen is expressed strongly in the mucosal glycoproteins of 25% of the 'non-secretor' population[37]; in these individuals, the I(Ma) determinant presumably is not further glycosylated by the blood group H, A or B monosaccharides and remains accessible. When adenocarcinomas arise in the gastric mucosae of 'secretors', the I(Ma) determinant behaves as a tumour-associated antigen, presumably because the blood group chains are synthesized incompletely.

The sialylated blood group Le^a, (structure 13, Table 1) defined by the hybridoma antibody 19.9 is another tumour-associated antigen found in certain tissues of certain individuals, but a normal antigen in others. This antigen is expressed strongly on glycolipids and glycoproteins extracted from adenocarcinomas of the colon, but not on those of the normal colon[34,39,40], but it has been detected among normal pancreatic glycolipids[34] and normal seminal fluid glycoproteins[41]. In glycoproteins extracted from gastric mucosae, this antigen (like the I(Ma) and FC10.2 antigens), however, is a normal component in 'non-secretors' and a tumour-associated antigen in 'secretors'[40]. The enzymatic basis of these antigenic changes requires investigation, particularly at the level of glycosyltransferase genes.

Apart from carbohydrate determinants shared commonly by glycoproteins and glycolipids, some structures which occur predominantly on glycolipids of the lactosyl, ganglio and the globo series (Table 2), have been shown also to behave as oncodevelopmental antigens recognized by hybridoma antibodies. These include: (1) the *N*-acetylneuraminic acid form of G_{D3} (structure 15, Table 2), recognized by the hybridoma antibodies R_{24} and 4.2 raised against human melanoma cell lines; (2) the 9-*O*-acetyl-*N*-acetylneuraminic acid form of G_{D3}, (structure 16, Table 2), recognized by antibody D1.1 raised against a neuroectodermal antigen of fetal rat and expressed also on human melanoma cells; (3) the blood group P^k determinant, (structure 19, Table 2), recognized by hybridoma 38.13 raised against Burkitt lymphoma cell lines; and (4) two epitopes on structure 21 (Table 2) behaving as the stage-specific embryonic antigens SSEA-3 and SSEA-4 of mouse embryos.

Thus, numerous studies have assigned to carbohydrate structures roles as differentiation antigens and oncofetal antigens. These structures are not confined to any one normal or neoplastic cell type. All such antigens detected by monoclonal antibodies and characterized at the determinant level have been associated with saccharides. These new observations with monoclonal antibodies agree with current knowledge about the genetics and structures of the blood group antigens and their precursors[15,42,43] and the differences in the carbohydrate moieties of the glycolipids of normal and neoplastic cells[9,44] and of various types of differentiated cells[45]. These differences presumably are the end results of either differences in the activities of glycosyltransferases, or in the availability of their substrates, or differences in glycosidase activities in various cell types. Thus, the hope that unique antigenic markers of tumour cells would be discovered and revolutionize tumour diagnosis and therapy is being replaced by the realization that such antigens may not exist.

The failure to discover unique antigenic markers of developmental stage or neoplastic state may reflect limitations in the methods of selection of hybridoma antibodies. This is not necessarily so, for certain autoantibodies and monoclonal antitumour antibodies produced by lymphocyte cell lines derived from patients with neuroectodermal tumours or melanomas are directed also at carbohydrates (structures 17 and 18, Table 2). Thus, the possibility must be considered seriously that: (1) saccharides are the much-sought surface markers that distinguish immature from mature cells and tumour cells from their normal counterparts; (2) the carbohydrate sequences, and/or some additional structures associated with them, may have specific roles in normal cell growth and differentiation; (3) the inappropriate biosynthesis or processing of carbohydrate structures may contribute to the disordered behaviour of tumour cells.

Role of saccharide antigens

Most of these carbohydrate antigens have unknown function. Interestingly, a high proportion of the hybridoma-defined anti-

Table 2 Differentiation antigens first detected by monoclonal antibodies or autoantibodies and identified subsequently as carbohydrate structures of glycolipids of the lactosyl, ganglio or globo series

	Structure	Designation	Cell association
Lactosyl series			
14	Galβ1→4Glc-Cer	T_5A_7 (lactosylceramide)	Myeloid cells, human[91]
15	Galβ1→4Glc-Cer ↑2,3 NeuAcα ↑2,8 NeuAcα	R_{24} 4.2 (G_{D3})	Melanoma, human[92,93]
16	Galβ1→4Glc-Cer ↑2,3 NeuAcα ↑2,8 Neu5,9Ac$_2\alpha$	D1.1	Neuroectoderm, rat, melanoma, human[94]
Ganglio series			
17	GalNAcβ1→4Galβ1→4Glc-Cer ↑2,3 NeuAcα	OFA-1 (autoantigen) (G_{M2})	Melanoma and fetal brain, human[95]
18	GalNAcβ1→4Galβ1→4Glc-Cer ↑2,3 NeuAcα ↑2,8 NeuAcα	OFA-2 (autoantigen) (G_{D2})	Melanoma, human[96] Neuroectoderm, human[97]
Globo series			
19	Galα1→4Galβ1→4Glc-Cer	38.13 (blood group P^k)	Burkitt lymphoma cell lines[98]
20	GalNAcα1→3GalNAcβ1→3Galα1→4Galβ1→4Glc-Cer	M1·22 25·8 (Forssman)	Embryos and embryonal carcinoma cells, mouse[3,4]
21	SSEA-4 NeuAcα2→3Galβ1→3GalNAcβ1→3Galα1→4Galβ1→4Glc-Cer SSEA-3	SSEA-3, SSEA-4	4- To 8-cell-stage embryos, mouse[99,100]

gens thus far elucidated are related to the blood group antigen system, possibly reflecting the ease of 'recharacterization' of known structures. Even the amounts of the major blood group antigens A, B and H, in organs of the human fetus change in successive stages of development[46]; this suggests that these carbohydrate structures also are differentiation antigens, but their physiological roles are still unknown. Among some other unexpected developments is the demonstration that most monoclonal antibodies against the receptor for epidermal growth factor (EGF) on the epidermoid carcinoma cell line A431 show specificity for blood group-related carbohydrate structures (reviewed in refs 47, 48, 102). Blood-group and related antigens are expressed strongly on the surface of the epidermoid carcinoma cell line A431 (refs 47, 49); the EGF receptor seems to be the major blood group active glycoprotein in this cell line. One of the monoclonal antibodies (TL5) raised against the EGF receptor of A431 cells[50] recognizes the blood group A antigen[49] and may behave as a growth factor agonist in certain conditions. This antibody does not compete with EGF nor does it have a direct stimulatory effect on fibroblasts, but in an experiment where the cell-bound antibody was crosslinked in the presence of anti-mouse antibodies, the fibroblasts took up tritiated thymidine[50]. If this stimulatory effect is mediated by perturbation of blood group A-active carbohydrate chains, blood group structures are likely to be receptors for certain (as yet undefined) regulators of cell proliferation[48], and systematic studies on the roles of this family of saccharides in the control of cell growth would be encouraged.

One approach to elucidate the roles of the developmentally-regulated carbohydrate structures (such as blood group-related carbohydrate chains based on Type 1 and Type 2 backbones) is to identify the cellular glycoproteins that carry them. This provided the first evidence[51] for their occurrence on the anion transport protein (band 3) of erythrocyte membranes and on high-M_r glycoproteins, including the leukocyte common antigen of human B lymphocytes and the sialoglycoproteins of human T lymphocytes[52,53], just as for the EGF receptor glycoprotein[47]. Well-characterized monoclonal antibodies may be used increasingly for studies of the carbohydrate moieties of glycoproteins and glycolipids.

Another approach is to perturb cell interactions during early embryogenesis (for example, those leading to the process of compaction) by using structurally-defined oligosaccharides as inhibitors. A reversal of compaction of mouse embryos with oligosaccharides expressing the SSEA-1 determinant has been reported[54]. In another study this was not found with free oligosaccharides[55], but an inhibition of compaction in the presence of a trivalent conjugate of this carbohydrate sequence was found[55]. An alternative approach, treating embryos with endo-β-galactosidase, provides evidence for the involvement of carbohydrate chains of poly-*N*-acetyllactosamine type in the compaction process[56]. Compacting embryos (at the 8- to 16-cell stage) decompacted experimentally in calcium-free medium and treated with endo-β-galactosidase, have a dramatically prolonged recompaction time. Endo-β-galactosidase cleaves specifically long-chain oligosaccharide backbones containing the sequence GlcNAc(β1→3Galβ1→3/4GlcNAc)$_n$, abundant on embryonic cells[22]; it abolishes the SSEA-1 activity associated with them[56].

A role for a specific carbohydrate structure in the metastatic properties of B16 melanoma cells of mouse could be that mutant cell lines with reduced metastasizing ability and an increased cell-to-cell adhesive property contain elevated concentrations of α1→3-fucosyltransferase and an increased surface expression of the SSEA-1 determinant[57]. The purified glycosyltransferase can act as a mediator of the adhesion of human fibroblasts[58]. These observations suggest that adhesion and reduced metastasis are mediated by the interaction of this glycosyltransferase on the surface of B16 mutant cells with acceptor substrates on other cells. These and some other observations on galactosyltransferase activities on the surface of embryonal carcinoma cells[59] support the hypothesis[60] that glycosyltransferases of cell surfaces may mediate cell-to-cell adhesion by interacting with acceptor substrates on neighbouring cells. *In vitro* experiments with immobilized α-mannosidase indicate that glycosidases also may serve as cell adhesion molecules[61].

Biological functions of carbohydrates

Biochemical (rather than immunochemical) experiments have allowed the assignment of roles to specific saccharide structures, all of which are potential antigens. For example, the blood anticoagulant activity of heparin results from its ability to bind with high affinity to the protease inhibitor anti-thrombin. This binding is mediated by a specific pentasaccharide sequence on the heparin molecule[62]. There is evidence also for important biological activities associated with other, non-anticoagulant oligosaccharide sequences in heparin: (1) the promotion of angiogenesis by intact heparin and the inhibition of angiogenesis by a hexasaccharide fragment derived from it[63] and (2) the inhibition of smooth muscle proliferation by an oligosaccharide fragment derived from the heparin of endothelial cells[64]. I suggest that the latter observation raises the important possibility that this heparin oligosaccharide sequence may be a receptor analogue for platelet-derived growth factor (PDGF). Some important functions have also been ascribed to structurally-defined sialoglycolipids (gangliosides). The ganglioside GQ_{1b} enhances greatly neurite outgrowth and cell proliferation in neuroblastoma cell lines[65]. Gangliosides G_{M1} and G_{M3} may modulate the phosphorylation (and hence the function) of the receptor for PDGF in a mouse fibroblast (3T3) cell line[66]. These are strong indicators of the importance of carbohydrate structures in the regulation of cell growth.

The role of terminal galactose residues of asialoglycoproteins as recognition structures for their clearance from serum by uptake into hepatocytes[67] and the importance of phosphorylation of mannose residues of lysosomal enzymes for their correct routing to lysosomes[68] are well established. This latter observation indicates clearly that modification of oligosaccharide sequences, for example, by phosphorylation, may change greatly their biological properties.

An important function assigned to specific oligosaccharide sequences in plants has been the eliciting of antimicrobial compounds, phytolexins. There is strong evidence to suggest that the active substances are oligosaccharide fragments released from the injured plant-cell walls and from the cell walls of fungi infecting the plant roots (reviewed in ref. 69). The corresponding carbohydrate binding molecules have not been identified. On the other hand, a variety of carbohydrate binding proteins (lectins) are distributed widely in plant and animal cells[70,103]. Although the precise functions of these lectins, in their tissues of origin are unknown, the biological effects of plant lectins on animal cells, for example, the induction of blast transformation of lymphocytes by phytohaemagglutinin, have been studied widely[70]. In transformed and mitogen-stimulated lymphocytes, we have detected[104] increased levels of proteins antigenically related to an animal lectin (soluble β-galactoside-binding lectin). Thus, it is possible that the lectin and related proteins are somehow involved in the regulation of cell growth. In fibroblasts and epithelial cells, we (S. R. Carding and T.F., cited in ref. 104) have detected several potential receptors for this lectin in the M_r range 10,000–180,000. It will be important to investigate whether growth factor receptors, such as the EGF receptor which contains carbohydrate chains with β-galactoside termini[47], interact with this and other endogenous lectins within or on the surface of cells.

As well as having roles as recognition structures for endogenous ligands, carbohydrate sequences of cell surfaces serve as receptors for infective agents and their toxins[71–75]. They may be important determinants of the tropisms of diverse infective agents. Furthermore, various strains of influenza virus have binding specificities for different sialic acid→galactose linkages and extracellular (soluble) sialoglycoproteins of the host may exert selective pressures resulting in the emergence of variant viruses with altered cell-binding specificities[76]. Thus, the

well-known properties of serum glycoproteins in inhibiting the attachment of viruses to cells and the differing sialyloligosaccharide sequences on the glycoproteins of different animal species may be important in the ecology of the influenza virus.

Studies on the adhesive specificity of the human pathogen *Mycoplasma pneumoniae* indicate that the autoimmune manifestation following infection (the production of high-titre autoantibodies to the erythrocyte antigen I) has its origin in the interaction of the infective agent with saccharide receptors of the host cells, conclusions reached following the observation that the receptors for this agent on human erythrocyte membranes are sialyloligosaccharides of Ii antigen type[77]. Thus, the post-infective anti-I autoantibodies can be considered 'anti-receptor' antibodies directed against the backbone structures of the receptor sequence, raising the possibility that the formation of complexes between the adhesive molecules of infective agents and specific saccharides of host-cell membranes may be an important mechanism for eliciting autoantibodies. The same principle may apply to other autoimmune disorders with anti-receptor antibodies where the causative agents are not yet known but infective agents are not excluded. In those instances where host-cell receptors are saccharide structures shared by several glycoproteins and glycolipids, as with *M. pneumoniae*, there will be cell-type and species differences in the receptor macromolecules[78], reflecting the differences in glycosylations. Hence, the biological effects of a given infective agent will differ accordingly. Presumably, such cell-type differences account for the different effects of *M. pneumoniae* on human T and B lymphocytes; *M. pneumoniae* triggers a mitogenic response in T lymphocytes but induces immunoglobulin secretion without mitogenesis in human B lymphocytes[79]. I suggest that many mechanisms of tropism and some of the transformation-related phenomena of oncogenic viruses are a function of their carbohydrate-binding (lectin-like) proteins.

Conclusions

Monoclonal antibodies have not revealed the much-sought, unique antigen markers of embryonic stage and neoplastic state; few of them may survive the critical assessment of the oncologist for the purpose of tumour diagnosis and therapy[80]. The antibodies characterized already and those awaiting characterization, however, are reagents which will become fundamental analytical tools for future studies of the glycoconjugates of whole cells and their receptors. Although much progress is being made on the structural analysis of glycoconjugates by physicochemical procedures, these are unlikely to supersede the sensitivity of monoclonal antibodies for visualizing the *in situ* disposition of the diverse oligosaccharide sequences in individual cells.

I thank my colleagues R. A. Childs, H. C. Gooi and E. F. Hounsell for constructive criticisms and Sally Schwarz for preparing the manuscript.

Importance of the 'shape' of the melting regime during partial melting of the mantle

M. J. O'Hara

Geology Department, University College of Wales, Aberystwyth, Dyfed SY23 3DB, UK and
Division of Geological and Planetary Sciences, California Institute of Technology, Pasadena, California 91125, USA

The amount of melt formed in individual stream lines of upper mantle rocks passing through a partial melting regime increases from zero at the edge to a maximum at the central axis. Relationships between aggregated liquid compositions from such melting regimes and the source mantle should be obained by integration of the appropriate equations for liquid composition taking into account the horizontal and vertical form of the melting regime. Misinterpretation of integrated liquid products from such regimes would be easy if too simple a model of the melting process is used.

GEOCHEMICAL effects of partial melting of upper mantle rocks have been explored over the past 16 years using relationships developed by Gast[1], Shaw[2] and Langmuir *et al.*[3]. Applications of these relationships to the prediction or interpretation of data sets for volcanic rocks have assumed implicitly that all parcels of the mantle processed through the partial melting regime undergo an equal amount of melt removal. Yet it was known throughout this time that the maximum temperature above the solidus and, therefore, the mass fraction of melt developed in parcels of mantle passing through the melting regime, will be at a maximum along the central axis and will decline to zero at the edges[4].

Consider one example of the consequence of using more sophisticated models—the case where mass fraction (F) of melt developed on each stream line increases to some central maximum (F_m) as a linear function of distance inward from the periphery, in a melting regime of semi-infinite lateral extent. Only half as much liquid will be developed in this first case as would be developed in a second, or 'simple', case where all the mantle which had encountered the melting regime underwent the same (maximum F_m) mass fraction of partial melting.

Now consider a totally incompatible element, wholly concentrated in the first drop of liquid to form along each stream line. The concentration of this element in the liquid derived in the first case will necessarily be just twice its concentration in the liquid derived in the second case. If the melting regime were circular in plan (for example, a plume) rather than of semi-infinite linear extent (for example, a mid-ocean ridge segment) the amount of liquid developed will be one-third that developed in the 'simple' case and the concentration of the totally incompatible element consequently will be three times that in the liquid derived in the 'simple' case.

Most attempts to invert the geochemistry of erupted basalt magmas to predict upper mantle chemistry, or to predict potential basalt compositions which might form by partial melting of particular mantle materials, have used the equations[1-3] which relate liquid, residue and source mantle compositions in the 'simple' case mentioned above. Clearly, when this is done inappropriately, there will be a tendency towards some combination of: (1) underestimation of the mass fraction of melting involved relative to the maximum amount actually developed (F_m); and (2) overestimation of the content of the totally incompatible element in (that is, the 'fertility' of) the source mantle.

Adoption of the more sophisticated melting model allows an immediate reconcilliation between field, petrographic and major element chemical features in upper mantle materials which point to large ($F_m \sim 0.25$-0.35) maximum mass fractions of melt removal (see, for example, ref. 5) and features of trace-element geochemistry which seem to point to very small mass fractions of partial melt removal (see, for example, ref. 6). The incompatible trace-element chemistry of the aggregated melts is dominated by liquid contributions from the periphery of the melting regime, where the mass fraction of melting is indeed small, whereas events in the central region tend to dominate the other aspects mentioned.

Adoption of the more sophisticated model has some relevance to the interpretation of the apparently higher 'fertility' (deduced using 'simple' models) of the mantle sources[7] which feed 'plume' type volcanism. Eventually, this model may reconcile the apparent fertility of plumes with the undeniable fact that significantly fertile mantle is too iron-rich, too well endowed with spinel and garnet and hence too dense to rise through residual mantle[8-11]. In principle, the sophicated model permits a less fertile mantle material, rising in a circular plan-form plume, to yield a liquid more enriched in incompatible elements than is obtained from neighbouring more fertile mantle undergoing melting in a linearly extensive melting regime.

Geochemical features suggestive of mixing of magmas from two or several sources when 'simple' models are used[12,13] may derive at least in part from the fact that in the sophisticated model the primary magmas are indeed complex mixed melts.

It may seem that the trace-element geochemistry of erupted basalts can still be inverted viably to yield upper mantle source characteristics using the 'simple' relationships with some average value for the mass fraction of liquid developed from the whole mass of mantle passing through the melting regime. But this is only true for totally incompatible elements.

Integration of the relationships described below yields expressions which in turn predict the liquid and residue compositions that might be produced in sophisticated melting regimes. These compositions cannot be inverted safely for elements which are not totally incompatible, using any average value of the mass fraction of partial melting inserted into the 'simple' relationships. Highly incompatible element concentrations predicted by the sophisticated model are lower than expectations from the best fit 'simple' model using a single average value of the melt fraction.

Discrimination of concentration between two highly incompatible elements of very similar distribution coefficient is achieved much more efficiently in the melts predicted by the sophisticated model. In 'simple' models, such discrimination can only be produced at very small mass fractions of partial melting. Interpretations based on 'simple' models (which may not be appropriate) may lead towards erroneous conclusions that particular magmas have been derived by exceptionally small mass fractions of partial melting or by extraction from mantle sources which have been depleted of their most highly incompatible elements in a previous small-scale melt extraction event.

Aggregated melt composition relationships

The treatment which follows is simplified greatly; it is used to explore some first-order effects which will result from the adoption of more sophisticated models of melting regimes, and is considered as an intermediate advance rather than a conclusion. (Several points for further refinement are noted in passing.) Partial melting is assumed here to result from the decompression of hot mantle ascending along an adiabat intersecting the solidus curve[4], but this assumption is not critical in the mathematical formulation.

The 'shape' of the melting regime has two components. The plan-form 'shape' is assumed to be either linear or circular (but solutions for the elliptical end-form would be desirable). It is further assumed that the amount of melt extracted is a maximum on the central axis or at the centre and falls off symmetrically towards the periphery. All melt extracted is assumed to be aggregated and tapped at the central axis only (tapping of liquids developed from sub-portions of a large melting regime has obvious relevance to the Galapagos Islands and sea mounts near spreading centres).

The cross-section 'shape' of the melting regime is defined here by the relationship between distance, y, from the edge of the melting regime (Fig. 1) relative to Y_m, the distance to the centre of the melting regime and F_y the maximum mass fraction of melt extracted from a parcel of mantle at distance y from the edge, relative to F_m (the maximum mass fraction of melt extracted from a parcel of mantle passing along the central axis of the regime). Melting of sub-spherical blobs is not addressed here.

The 'parcel' of mantle is defined as a very small mass or volume of mantle of width dy (unit length perpendicular to the cross section) and height dh (such that an additional mass fraction of partial melt, dF_y is produced within it as it moves upwards a distance, dh, along the stream line).

The appropriate relationships have then been integrated[14] on the following assumptions: First,

$$(y/Y_m) = (F_y/F_m)^n \quad (1)$$

where $n > 0$ (alternative assumptions for the relationship might yield a more easily integrated expression, advantageous because it would allow inversion of data sets to obtain the important parameters F_m and n).

Second, the partial melting process affecting each individual parcel of mantle produces a continuous partial melt (CPM), a process in which some mass fraction of the residue is trapped liquid, but in which further liquid is drained continuously from the parcel as melting proceeds. Each new infinitesimal increment of liquid formed is well mixed with the trapped liquid and balanced by the infinitesimal decrement of melt removed from that mantle parcel at the same step. The process has been modelled using the familiar relationship[2] for the composition of a perfect fractional partial melt (PFPM).

$$C_L/C_S = \frac{(1-f_y)^{1/D^*-1}}{D^*} \quad (2)$$

C_L is the concentration of an element in the liquid present in (or removed from) the parcel at the stage when mass fraction f_y of the original parcel has been removed by the CPM process (this parcel of mantle will yield ultimately a maximum mass fraction of melt F_y, where $F_y < F_m$). C_S is the concentration of the element in the original mantle parcel before the onset of melting and melt removal. The effects of trapped liquid are taken into account in the formulation of the bulk distribution coefficient, D^* as

$$D^* = D(1-z)+z \quad (3)$$

where D = concentration of element in the bulk crystal assemblage divided by the concentration of element in the liquid and z is the mass fraction of the trapped liquid residue. (Trapped liquid is treated simply as another residual phase for which the distribution coefficient happens to be unity.)

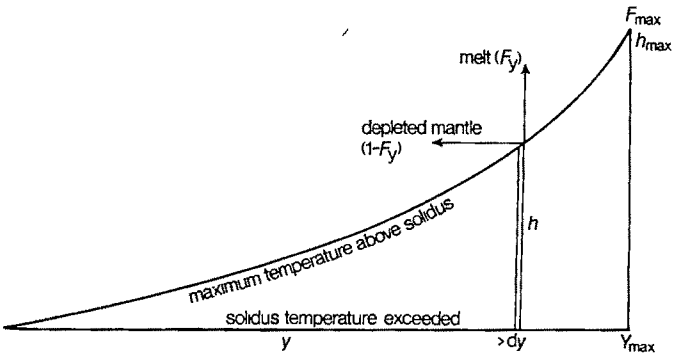

Fig. 1 Half cross-section of a hypothetical upper mantle melting regime (adapted and simplified from ref. 4) illustrating the relationships between the distance y of a stream-line, height h, in the partial melting regime and Y_m, the distance to the centre. The mass fraction F_y of melt extracted along this stream line is assumed proportional to h and the 'shape' of the melting regime is defined by the relationship between y and F_y (see text). Arrows labelled 'depleted mantle' and 'melt' are stylized and indicate no more than physical separation of melt from residue somewhere in the regime.

Equations (2) and (3) yield a precise description of the process at all values of D, z and f_y (full integration from mass balance equation on request from the author) and no problems arise with melt not collected from the periphery because f_y, F_y and F_m are defined as the mass fractions of melt which are collected.

Third, z, D and hence D^* are assumed constant for all parcels of mantle throughout the melting process and C_S is also assumed constant in time and space. (Subsequent developments must examine the consequences of the variations in D which accompany both the changes in the proportions of the crystal species which will occur when F_m is large and the changes in phase assemblage and liquid structure which will occur when the melting regime extends through a significant range of pressure. In principle, these complications can be introduced into the numerical integration of the relationships derived below, but the assumptions made here are necessary for the analytical solutions presented.) Note, however, that for very highly incompatible elements with $D < 0.005$, the value of D^* will be dominated by the mass fraction of trapped liquid, z, if this is greater than ~0.005 (0.5%).

Fourth, all decrements of melt removed from all parcels of mantle are aggregated without any further interaction with source material or residues, and well mixed to form an accumulated perfect fractional partial melt (APFPM) or an accumulated continuous partial melt (ACPM). The composition of the APFPM or ACPM derived from a single mantle parcel during its passage through the melting regime, or from all parcels along a single mantle stream-line through the regime at one instant, is then obtained from the familiar relationship[2]

$$\bar{C}_L/C_S = \{1-(1-F_y)^{1/D^*}\}/F_y \quad (4)$$

which is the integral of equation (2) between $f_y = 0$ and $f_y = F_y$.

Fifth, residue stream-line patterns and F_y along each flow line are assumed to remain constant with time (that is, the process is in a steady state).

Sixth, the APFPMs or ACPMs from each mantle stream line are in turn aggregated to yield a complex accumulated perfect fractional (or continuous) partial melt (CAPFPM or CACPM) which constitutes the primary magma segregated from the partial melting regime. The relationship between the concentration of an element $\bar{C}_L$ in this CAPFPM or CACPM and its concentration in the source C_S, is obtained by integrating $\bar{C}_L/C_S$ (equation 4) for $F_y = 0 \rightarrow F_m$ over the cross-section shape and along (linear) or around (circular) the plan-form of the melting regime, as

follows:

$$\bar{C}_L/C_S = \left\{\int_0^{F_m}\left[\begin{matrix}\text{relative length in planform}\\ \text{to which result applies}\end{matrix}\right]\times\left[\begin{matrix}\text{concentration of element}\\ \text{in liquid increment}\end{matrix}\right]\times\left[\begin{matrix}\text{mass fraction of liquid}\\ \text{having this concentration}\end{matrix}\right]dy\right\} - \left\{\int_0^{F_m}\left[\begin{matrix}\text{relative length in planform}\\ \text{to which result applies}\end{matrix}\right]\times\left[\begin{matrix}\text{mass fraction of liquid}\\ \text{having this concentration}\end{matrix}\right]dy\right\} \quad (5)$$

In the linear planform case the relative lengths in planform are all the same, hence the first bracket top and bottom becomes unity. In the circular planform case the relative lengths are given by $2\pi(1-y/Y_m)$ which is $2\pi(1-(F_y/F_m)^n)$. The middle bracket on the top line contains the expression from equation (4) above. The last bracket, top and bottom, is simply F_y.

Substituting, from equation (1), $dy=(nY_m/F_m^n)F_y^{n-1}\,dF_y$ and cancelling constants n, F_m, Y_m in top and bottom lines, one obtains in the linear planform case

$$\frac{\overset{\text{CAPFPM}}{\underset{\text{LINEAR}}{\bar{C}_L}}}{C_S} = \frac{\int_0^{F_m}\left[\frac{1-(1-F_y)^{1/D^*}}{F_y}\right]F_yF_y^{n-1}\,dF_y}{\int_0^{F_m}F_yF_y^{n-1}\,dF_y} \quad (6)$$

or, in the circular plan case

$$\frac{\overset{\text{CAPFPM}}{\underset{\text{CIRCULAR}}{\bar{C}_L}}}{C_S} = \frac{\int_0^{F_m}\left[1-\left(\frac{F_y}{F_m}\right)^n\right]\left[\frac{1-(1-F_y)^{1/D^*}}{F_y}\right]F_yF_y^{n-1}\,dF_y}{\int_0^{F_m}\left[1-\left(\frac{F_y}{F_m}\right)^n\right]F_yF_y^{n-1}\,dF_y} \quad (7)$$

Both expressions may be further simplified by cancellation of an F_y in the top line and summing powers of F_y in the bottom line before commencing numerical or analytical integration.

Seventh, the derivation of equations (5) and (6) assumes that each decrement of melt removed from each parcel of mantle undergoes no further chemical interaction with any other parcel of mantle or residue, but this represents only one extreme possible assumption. Another (not the only other) extreme assumption is that each decrement of melt flows upward along the mantle stream line, remaining in perfect equilibrium with the residues, and is then aggregated. This leads to the alternative relationship to that given in equation (4),

$$\bar{C}_L/C_S = 1/[D^*+F_y(1-D^*)] \quad (4')$$

which is familiar[2] as a form of the relationship for the composition of a perfect equilibrium partial melt (PEPM) product developed where mass fraction F_y of the original source has become removable melt. That this is true can be demonstrated by integration of the appropriate mass balance equations, but may also be appreciated intuitively. All the melt (mass fraction F_y) from the whole stream line must pass through and equilibrate with the final residue, mass fraction $(1-F_y)$ leading to equation (4') by simple mass balance. (Note the separate increments of melt composing the mass fraction F_y commenced their travel at different times). Equation (4') is valid provided n and F_m are constant, which is not guaranteed in real geological situations.

Integration as before then yields the alternative expressions for the linear plan case

$$\frac{\overset{\text{CAPEPM}}{\underset{\text{LINEAR}}{\bar{C}_L}}}{C_S} = \frac{\int_0^{F_m}\left[\frac{1}{D^*+F_y(1-D^*)}\right]F_yF_y^{n-1}\,dF_y}{\int_0^{F_m}F_yF_y^{n-1}\,dF_y} \quad (6')$$

and for the circular plan case,

$$\frac{\overset{\text{CAPEPM}}{\underset{\text{CIRCULAR}}{\bar{C}_L}}}{C_S} = \frac{\int_0^{F_m}\left[1-\left(\frac{F_y}{F_m}\right)^n\right]\left[\frac{1}{D^*+F_y(1-D^*)}\right]F_yF_y^{n-1}\,dF_y}{\int_0^{F_m}\left[1-\left(\frac{F_y}{F_m}\right)^n\right]F_yF_y^{n-1}\,dF_y} \quad (7')$$

Computation of the expressions in equations (6), (7), (6') and (7') is best carried out by numerical integration, particularly for the case of very highly incompatible elements with low values of $D^*(<0.003)$. Analogous expressions may be written to describe the average residue compositions[14].

However, integration of equations (6) and (7) by substitution by the chain rule and by parts, yields in the general case, an infinite series[14] which may be rearranged in the forms given in equations (8) and (9) below for the linear and circular plan forms respectively.

$$\frac{\overset{\text{CAPFPM}}{\underset{\text{LINEAR}}{\bar{C}_L}}}{C_S} = \left[\frac{n+1}{n}\right]\left\{\left[\frac{1-(1-F_m)^{1/D^*}}{F_m}\right]-\left[\frac{(1-F_m)^{1/D^*-1}}{D^*}\right]\{\text{series 1}\}\right\} \quad (8)$$

where

$$\{\text{series 1}\} = \left\{\frac{1}{(n+1)}+\frac{F_m}{(1-F_m)D^*}\frac{(1-D^*)}{(n+1)(n+2)}+\cdots+\frac{Q^{p-1}n^!(1-D^*)(1-2D^*)\cdots(1-(p-1)D^*)}{(n+p)!}\right\}$$

and where $Q=[F_m/(1-F_m)D^*]$ and the general term is written for the pth term of the subseries, designated here as {series 1}.

$$\frac{\overset{\text{CAPFPM}}{\underset{\text{CIRCULAR}}{\bar{C}_L}}}{C_S} = \left[\frac{(n+1)(2n+1)}{2n^2}\right]\times\left\{\left[\frac{1-(1-F_m)^{1/D^*}}{F_m}\right]-\left[\frac{(1-F_m)^{1/D^*-1}}{D^*}\right]\times[2\{\text{series 1}\}-\{\text{series 2}\}]\right\} \quad (9)$$

where

$$\{\text{series 2}\} = \left\{\frac{1}{2n+1}+\frac{Q(1-D^*)}{(2n+1)(2n+2)}+\cdots+\frac{Q^{p-1}(2n)!(1-D^*)(1-2D^*)\cdots(1-(p-1)D^*)}{(2n+p)^!}\right\}.$$

The term $(1-(p-1)D^*)$ in the general term of these series must eventually become negative for $D^*>0$ and successive terms thereafter are alternately positive and negative. The series will converge provided $F_m/(1-F_m)<1$, that is, $F_m<0.5$ (the majority of geologically reasonable cases) and evaluation will terminate, with all later terms being zero, at the $(1/D^*+1)$th term if $1/D^*$ is an integer.

Equations (8) and (9) may be simplified for analytical purposes to

$$\left[\begin{matrix}\text{Complex}\\ \text{aggregated}\\ \text{melt}\end{matrix}\right] = \left[\begin{matrix}\text{shape}\\ \text{factor}\end{matrix}\right]\left\{\left[\begin{matrix}\text{APFPM}\\ \text{at } F_{max}\end{matrix}\right]-\left[\begin{matrix}\text{PFPM}\\ \text{at } F_{max}\end{matrix}\right]\left[\begin{matrix}\text{series}\\ \text{factor}\end{matrix}\right]\right\} \quad (10)$$

Equation (10) may be stated as follows: The concentration of an element in a CAPFPM or CACPM product will be that expected in an APFPM (or ACPM) product developed at the maximum mass fraction of partial melting minus the concentration of that element developed in the last extracted drop of a PFPM (or CPM) product at the same maximum mass fraction of melting multiplied by a series term whose value is a function of F_m, D^* and the power function n; the whole of the above multiplied by a shape factor which is a function of the power n alone.

Evaluation of the relationships

Some important properties of equations (8) and (9) are: First, when $D^*=0$ (totally incompatible element), $\bar{C}_L/C_S=$[shape

factor][$1/F_m$]. Second, when $D^* = 1$, $\bar{C}_L/C_S = 1$ (logical). Third, when $D^* \to \infty$ (totally compatible element), $\bar{C}_L/C_S \to 0$ (logical). Fourth, when $0 < D^* < 1$, $\bar{C}_L/C_S$ is less than would be expected in a simple APFPM product at the appropriate F_m multiplied by the shape factor. The quantity by which it is less is given by [PFPM at F_m] {series factor} [shape factor]. As D^* becomes smaller, the [PFPM at F_m] term passes through a maximum where $D^* \simeq F$ and thereafter becomes very rapidly smaller. Simultaneously, the {series factor} increases in magnitude. The net effect is that this subtracted quantity passes through a maximum (and $\bar{C}_L/C_S$ through a minimum relative to the simple APFPM term) at some intermediate value of D^* which is a function of F_m and n. The resultant values of $\bar{C}_L/C_S$ nevertheless seem to discriminate increasingly efficiently between elements with very small but fixed differences of D^* as D^* itself decreases.

Fifth, as $n \to 0$ (the mass fraction of partial melting is small over most of the regime but increases sharply close to the central axis), the [shape factor]$\to \infty$ and $\bar{C}_L/C_S$ tends to very large values when $D^* < 1$, very small values when $D^* > 1$. The parameters $n = 1$, $D^* = 0$ describe the case discussed in the introduction. Sixth, when $n \to \infty$ (the mass fraction of melt extracted is very close to F_m for all flow lines through the regime) the differences between equations (8) and (9) disappear since all terms in {series 1} and {series 2} tend to zero. The [shape factor]$\to 1$, and $\bar{C}_L/C_S \to [1-(1-F_m)^{1/D^*}]/F_m$ which in the limit is identical with equation (4).

Seventh, the [APFPM] term in equation (10) yields concentrations which differ little from those of PEPM (see equation 4'), particularly when F_m is substantial. When F_m is substantial (0.2–0.4), this term is very inefficient at discriminating between very highly incompatible elements with small differences of D^*. To obtain good discrimination using this this term, it is necessary to reduce F_m to values ~0.01 rather than ~0.3.

Eighth, the [PFPM] term in equation (10) yields results which differ dramatically from the [APFPM] term when D^* is small and F_m is substantial. Moreover, the [PFPM] term discriminates very efficiently between very highly incompatable elements of very similar D^*, but at the cost of generating minute concentrations of these elements in the [PFPM] product when F_m is substantial. For very highly incompatible elements this term would be insignificant were it not for the multiplier contained in the series term (see below).

Finally, the {series factor} in equation (10) may contain some very large terms, particularly when F_m is large and D^* and n are small. When D^* is small, the largest terms in the series are grouped about $1/2D^*$ terms into the series; all the first $1/D^*$ terms are positive and all other terms are small (for example, if $D^* = 0.001$, the largest terms contributing to the {series factor} are ~500 terms into the series, and involve evaluation of quantities such as $Q^{499} \simeq 400^{499}$; $(n+p)! \sim 501!$).

Geological significance

These and other properties[14] of equations (8), (9) and (10) have important implications for the interpretation of major and trace element geochemistry and experimental petrology data for natural lavas, which include:

(1) Even true primary magmas (developed according to the above scenario) would not be in phase or chemical equilibrium with any specific residue composition (although the discrepancy may be small in some respects); nor would the bulk CAPFPM product be in (conventional) chemical equilibrium with the bulk residue from the process.

(2) ('Effective' bulk distribution coefficients, defined as D' = (concentration of element in CAPFPM bulk residue) divided by (concentration of element in CAPFPM bulk liquid extract), may differ markedly from D or D^*. In the case of very highly incompatible elements when n is small and z relatively large, D' may be much larger than D, thus reducing greatly the efficiency of the partial melting process in 'stripping' the mantle of its very highly incompatible elements.

(3) By virtue of the [shape factor], concentrations of very highly incompatible elements in CAPFPM products will be significantly higher in the linear plan case than in simple APFPM products of the same source mantle and higher still in the circular plan case, even if the power factor n remains constant. By virtue of higher thermal losses per unit volume from a circular plan regime than from a linear plan regime, the power factor n is likely to be smaller in the circular plan case than in the linear plan case, enhancing the effect already noted. These effects could be misinterpreted easily as products of mantle heterogeneity, as outlined in the introduction.

(4) The CAPFPM product is much more efficient at fractionating two very highly incompatible elements of similar D^* than is a 'simple' APFPM product a equivalent F or an 'average' value of F (see ref. 14). This effect could reinforce the readily available misinterpretation (see (3) above) that very small mass fractions of partial melting are required to explain the geochemistry of erupted products; or lead to a further misinterpretation that D^* values must be still lower, that is, that mass fractions of trapped melt in the residual mantle must be lower than is actually the case.

(5) There is a disturbing resemblance between the potential misinterpretations of CAPFM products identified above and the principal conclusions of most publications in the field of igneous geochemistry in the past 15 yr containing interpretations based upon simpler models of the partial melting process. I do not argue here that there are no differences in 'fertility' of different portions of the mantle, or that small mass fractions of partial melt are not, on occasion, extracted, or that large portions of the mantle have not suffered a small fractional melt extraction at some earlier stage of their history. These are probable and readily acceptable conclusions. I do, however, suggest that the geochemical evidence needs to be re-evaluated in order to remove any spurious effects and,thereby, place these conclusions on a more secure foundation.

Alternative assumption integration

Equations (6') and (7') may also be integrated to yield results of the form

$$\begin{bmatrix}\text{Complex}\\ \text{aggregated}\\ \text{melt}\end{bmatrix} = \begin{bmatrix}\text{shape}\\ \text{factor}\end{bmatrix}\begin{bmatrix}\text{PEPM}\\ \text{at } F_{max}\end{bmatrix}\begin{bmatrix}\text{series}\\ \text{factor}\end{bmatrix} \qquad (10')$$

Shape factors are as before; the PEPM term at F_m is analogous to equation (4') above and the {series factor} in equation (10') is either

{series 3}

$$= \left\{\frac{nn!}{(n+1)!} + \frac{Snn!}{(n+2)!} + \frac{2S^2nn!}{(n+3)!} + \cdots + \frac{(p-1)!S^pnn!}{(n+p)!}\right\}$$—linear case

or

$$[2 \times \{\text{series 3}\} - \{\text{series 4}\}]$$—circular case

where

$$\{\text{series 4}\} = \left\{\frac{2n(2n)!}{(2n+1)!} + \frac{S2n(2n)!}{(2n+2)!} + \cdots + \frac{(p-1)!S^p2n(2n)!}{(2n+p)!}\right\}$$

and $S = [F_m(1-D^*)]/[D^* + F_m(1-D^*)]$.

These relationships differ from those given in equations (8) and (9) above in that they do not contain the subtracted term which produces the strong discrimination between elements of like distribution coefficient. Although it is true that the [PEPM] term produces much the same values of C_L as the [APFPM] term at constant F, it is also true that the [PEPM] term in its own right discriminates much more strongly between highly incompatible elements than does the [APFPM] term. Hence, the previous conclusions (1) (3) and (4) remain valid and (4) is in fact strengthened (see ref. 14). Conclusion (2), however, is not valid as stated. The effective bulk residue–bulk liquid distribution coefficient is D^*. The PEPM process does not strip incompatible elements from the residue with the high efficiency of the APFPM or CAPFPM processes.

The width of geochemical and residual elevation anomalies along the Mid-Ocean Ridge System decrease as both the distance between migrating ridge segments and related hotspots and the local geochemical dispersion in the anomalies increase. These observations provide further evidence that flows of mantle plumes in the upper mantle are deflected by migrating ridge sinks once they override hotspots.

THE problem of mantle heterogeneities is related closely to that of mantle dynamics[1]. Two extreme models are being pursued currently: one hypothesis considers the dispersion of randomly distributed domains rich in incompatible trace elements, passively embedded in a convecting mantle matrix relatively depleted in such elements and related radiogenic isotopes[2–5]. The second considers relatively fixed sources of incompatible element-rich domains, dynamically buoyant, rising as plumes or chains of blobs beneath hotspots which interact and mix with the incompatible element-depleted asthenosphere normally feeding migrating ridges[6–10]. Thus, migrating ridges act as sinks and mantle plumes as sources in this model[11].

We have shown recently in Galapagos[12–14] and South Atlantic[15] regions that ridge segments, once centred on a hotspot but since migrated away as far as 850 km, continue to sense and accrete material with hotspot geochemical signatures. Geochemical anomalies may also have decreased in length, local variability may have increased and the associated ridge elevation anomalies may have decreased as the distance from such ridge segments to nearby hotspots has increased. These observations provide additional evidence for a connecting channel which may develop and extend between the hotspot (the source of large-ion lithopile element (LILE)-rich material) and the migrating ridge (the sink), as proposed initially by Morgan[11] and Vink[16] purely on the basis of the tracks left by anomalous constructional volcanism on the sea floor. We also suggested that the flow of plume material towards the migrating ridge-sink becomes discontinuous, perhaps schlieren-like[15].

Here, I extend the testing of this hypothesis by considering more quantitatively how the width of these geochemical and residual elevation anomalies along the ridge crest vary either with distance from migrating ridges to nearby related hotspots, or the time since these ridge segments were located on such hotspots, or current spreading rates. On the basis of these empirical observations and very simple theoretical considerations, I then examine the consequences of this model in predicting the probable geometric pattern and evolution of the connecting flow channels, mixing conditions and constraints on mantle plume fluxes.

Methodology and results

Four major along-ridge geochemical and depth profiles were used as the database (Fig. 1). These include the Galapagos Spreading Centre (83–102° W)[12–14], the North Atlantic from 79 to 28° N[17,18], the South Atlantic from 0° to 47° S[15] and the Gulf of Aden (42–57° E; refs 19, 20 and J.-G.S., unpublished data). The four profiles combined represent about 15,430 km of ridges from the 60,000–70,000-km-long Mid-Ocean Ridge system. The average sample interval is 42 km ± 46 (1 s.d.). These four profiles comprise 11 recognizable anomalies whose widths are also shown in Fig. 1. The anomaly widths were compiled regardless of whether they represent long regular gradients, as for the ridge-centred hotspots such as Iceland, the Azores and Afar, or irregular spikes with large local dispersion, as for the more distant hotspots such as in the South Atlantic (Fig. 1). Of these 11 anomalies, 9 can be linked readily to a nearby hotspot known or suspected to have influenced the accreting crust at the ridge axis in these regions. Two could not (the 45° N anomaly in the North Atlantic and the short wavelength anomaly in the Gulf of Aden at 45.5° E). These two cases require detailed consideration which will be treated elsewhere with future tests of our model. Table 1 tabulates these geochemical relationships, including their distance to known or suspected hotspots, and the time since these ridge segments were centred on the ridge using plate-reconstructions in the framework of fixed hotspots[21–24]. I have also included in Table 1 corresponding current spreading rates taken from ref. 25 and the corresponding maximum residual elevation anomalies above the 2,900-m reference depth of normal ridges suggested by the compilation of Vogt[26] and Anderson *et al.*[27]. Whenever possible, I have attached in Table 1 probable errors associated with these parameters, such as uncertainties related to hotspot locations or plate reconstructions, major fracture zone offsets over the anomalies and sampling coverage and density.

Figure 2 shows that there is a good inverse correlation between the geochemical anomaly-width (W) and the distance (y) from the centre of these anomalies to that of the hotspot suspected or known to be linked to these anomalies (Fig. 2*a*), or with time (t) since these ridge segments were centred over these hotspots (Fig. 2*b*). For reference, these two correlations may be expressed by the empirical relations $W = (1{,}010 - 24.5\ (y)^{1/2})$ and $W = (992 - 53.6\ (t)^{1/2})$ respectively, with W and y in km and t in Myr, with correlation coefficients r^2, respectively, 0.85 and 0.89. The somewhat large deviation of the Jan Mayen hotspot from the W versus y reference curve may reflect the uncertainty in the exact location of the ridge axis on the platform and the location of this hotspot. I chose it arbitrarily to be centred on Jan Mayen Island, but this need not necessarily be the case[28]. The residual ridge-elevation anomaly (ΔE) and associated geochemical anomaly-width also decreases sympathetically (Fig. 3*a*). A linear relation $\Delta E = -0.34 + 3.13 \times 10^{-3}\ W$, with ΔE and W in km, can be used as reference (with the Azores point excluded) or $\Delta E = -0.040 + 2.47 \times 10^{-3}\ W$ (with the Azores point included) with $r^2 = 0.66$ and 0.54, respectively. The two intercepts are, within the uncertainties, close to zero, as expected for normal ridges without geochemical anomalies ($W = 0$) and normal elevation (that is, $\Delta E = 0$, or a reference depth of 2.9 km adopted from ref. 26). The empirical relationship with a linear

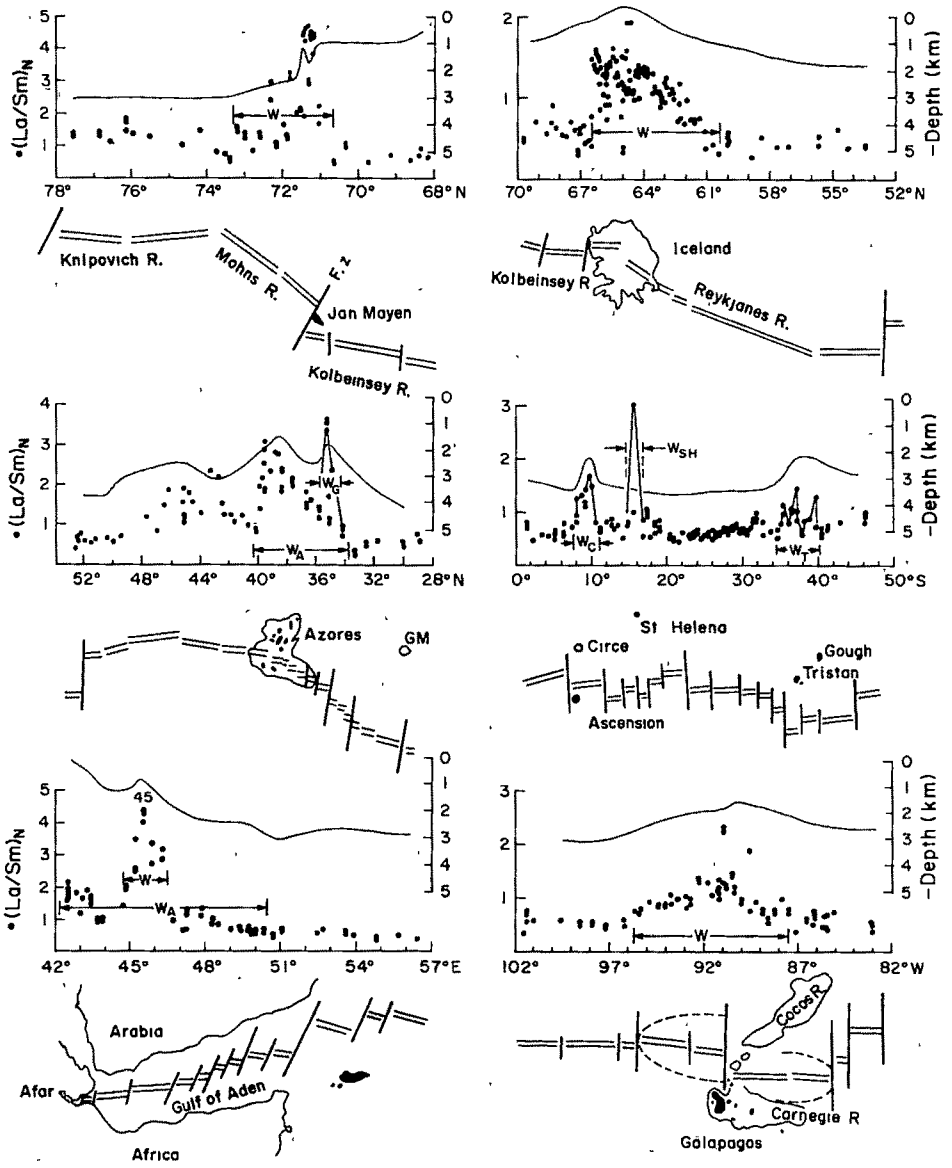

Fig. 1 La/Sm database used for determining the width (W) of geochemical anomalies along ridge axes near hotspots (left scales). Sources of profiles are: Mid-Atlantic Ridge profiles 78–71° N, 71–28° N and 0–47 °S from refs 18, 17 and 15, respectively; Galapagos 102–82° W from ref. 12; Gulf of Aden 42–57° E (from J.-S.G., manuscript in preparation). La/Sm_N is the La/Sm ratio normalized to chondrites; solid-line profiles represent the depth of sample recovery on the ridge axis, smoothed out with a method of moving average of ±100 km from each station. These depth profiles approximate the elevation of the ridge axis (see Table 1 for more exact values).

* Used in Figs 2, 3. † Maximum residual elevation of geochemically anomalous ridge segment over and above a normal depth of 2.9 km adopted from ref. 26, using data from ref. 26 and modified from my own observations during dredging.

best fit forced through the origin and the Azores point included is $\Delta E = 2.42 \times 10^{-3}$ W, with $r^2 = 0.87$. Vogt[26] has shown that the residual ridge anomaly located on or near hotspots is inversely related to spreading rates. Figure 3*b* shows that the residual ridge elevation anomaly is also related to the distance of these anomalous ridge segments to their corresponding hotspot. A possible empirical relationship is $\Delta E = 2.7 - 7.7 \times 10^{-2}(y)^{1/2}$ or $\Delta E = 3.0 - 9.2 \times 10^{-2}(y)^{1/2}$, with ΔE and y in km and r^2 of 0.75 and 0.87, with or without the Azores point, respectively. The possible departure of the Azores hotspot from the correlation involving the residual ridge elevation anomaly may be related to the fact that this hotspot has become ridge-centred to its present position only 9 Myr ago, judging from kinematic plate reconstructions[21-24], as well as geochemical results from the IPOD Leg 82 sampling grid in the region[29]. The Mid-Atlantic Ridge segment just north of the Azores passed over this hotspot once before, ~38 Myr ago[21-25]. Finally, I note that there is apparently no correlation between the anomaly-width and present spreading rates, although the range of spreading rate is limited mostly to 0.8–2 cm yr^{-1} half-rate, with one exception (Galapagos, 2.8–3.1 cm yr^{-1}) (Fig. 2*c*).

The above correlations suggest that as the ridge migrates away from the hotspot, both the width of the geochemical anomaly and associated anomalous elevation caused by the hotspot decrease progressively with time. The spreading rate does not seem significantly influential, at least over the small range so far investigated.

These regularities suggest strongly that some connection exists between hotspots and migrating ridge segments which are anomolous geochemically and in residual elevation. This evidence provides further support for the development of a lateral flow, maintained between these migrating ridge sinks and corresponding mantle plumes, since the time when these ridges were initially centred on these hotspots[15].

Modelling

Ridge-centred hotspot case. We have proposed previously that along-ridge geochemical gradients about ridge-centred hotspots can be modelled by a binary mixing model comprising as end members the LILE-rich blobs and the LILE-depleted asthenosphere[7-10]. The model requires that the blob delivers material at a rate independent and in excess of the rate of accretion by sea-floor spreading over the blob; the plume tends to elevate the region. The model also assumes that in the absence of a plume, accretion is passive and results simply from the divergence of the plates. The excess of blob material tends to pile up and form thicker crusts and is also accommodated by some flow outward along the ridge which acts as a sink. The mixing proportion (P) of blob material relative to the total mass of material accreting per unit ridge-length could decrease from unity over the plume (providing that no dilution with the depleted asthenosphere took place while travelling through it, or that the melting-zone width across the ridge is smaller than that of the blob) to zero at the end of the gradient where plume material has been completely used up by the accretion process (Fig. 4). We have shown previously that by estimating the trace-element content and the isotopic composition of the two end members (or Sm content and La/Sm ratios), the variation of P along the ridge axis (taken as the x direction) can be determined readily from the isotopic ratio variation (or La/Sm; see refs 12, 13). We can also estimate the minimum flux of the blob (Q), assuming that the gradient in La/Sm represents a quasi-steady state, namely:

$$Q = 2\int_{x=0}^{x=L} H(x)\, S(x)\, P(x)\, dx \qquad (1)$$

Observations suggest that the crustal thickness (H) and the full spreading rate (S) may both be functions of the distance (x) from the blob. In the evaluation of the physics of the process, it is probable that $H(x)$ would be dependent on $S(x)$. To illustrate the point simply, however, I assume in Fig. 4 that: (1) the blob is a point source at $x = 0$; (2) the two gradients are

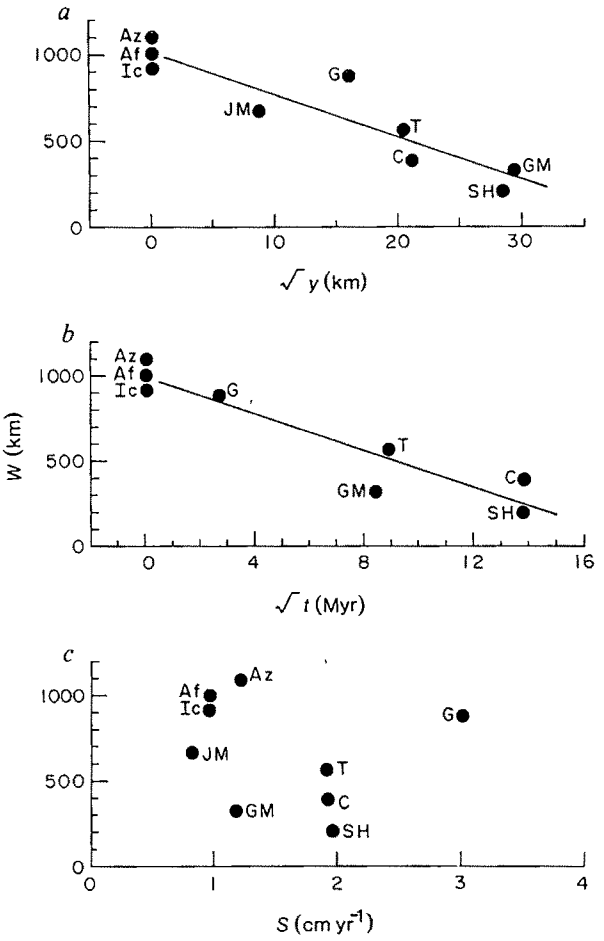

Fig. 2 Geochemical anomaly width (W) versus· *a*, square root of present distance (y) of associated hotspot to the geochemical anomaly on migrating ridge (determined from Fig. 1); *b*, square root of time (t) since the ridge was centred on associated hotspot (determined from refs 22–24); and *c*, half spreading rates (S) (determined from ref 25). All values used, including symbols used for hotspot names, are listed in Table 1. Note the good best-fit inverse linear correlation of W with $y^{1/2}$ and W with $t^{1/2}$ with correlation coefficients r^2 of 0.85 and 0.89 respectively, but lack of correlation of W with S.

placed symmetrically about the blob at $x = 0$, hence the factor two in equation (1); (3) the two end-member materials have essentially the same density, thus $P(x)$ represents volumetric proportions and Q is in km^3 yr^{-1}, if S is in km yr^{-1}; (4) H and S are constants independent of (x); (5) P varies linearly with x and is given by $P = 1 - (x/L)$, with $(0 \leq P \leq 1$; Fig. 4). Under these conditions, integration of equation (1) gives

$$Q = HSL = HSW/2 \qquad (2)$$

or

$$W = 2Q/HS \qquad (3)$$

where W is twice the length of gradients distributed symmetrically about the blob.

Thus, for ridge-centred blobs $W = 2Q/HS$ and is directly proportional to the blob flux and inversely proportional to S and H. For a given plume flux and constant crustal thickness, W or the length of the gradient L, should decrease with increasing spreading rate from one ridge-centred hotspot to another.

In reality, equation (1) must be integrated separately for each ridge-centred hotspot situation, with different boundary conditions and appropriate $H(x)$, $S(x)$ and $P(x)$ functions. In such cases, the relation of Q with L or W may be of a higher order than indicated in equations (2) or (3). Minimum estimates of plume fluxes can be made by this method and will be reported on in detail elsewhere.

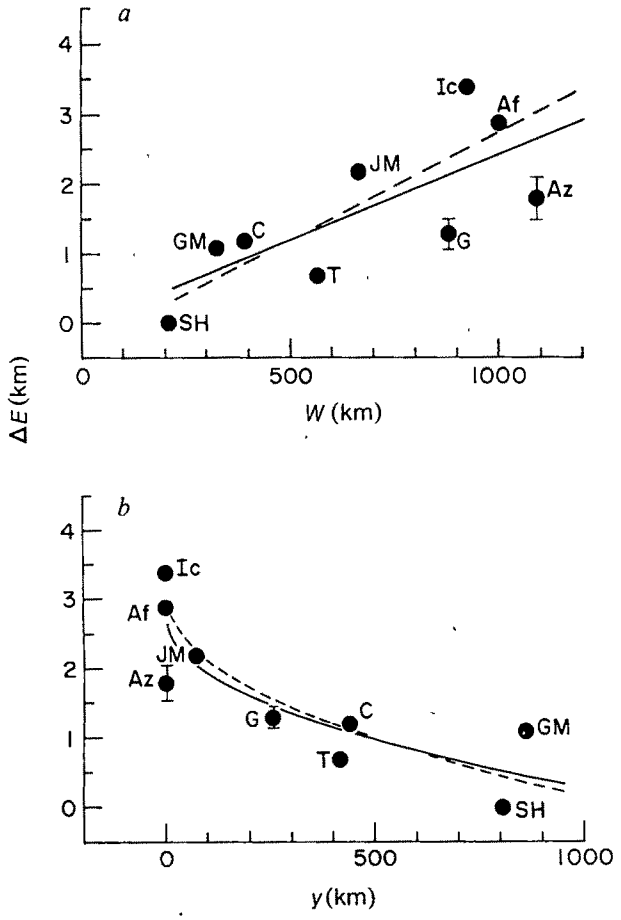

Fig. 3 Residual elevation (ΔE) of ridge axis over geochemical anomalies versus: *a*, geochemical anomaly width W (solid and dashed lines are linear best-fits including and excluding the Azores, respectively and the correlation coefficients are respectively, 0 54 and 0.66); *b*, distance (y) of hotspot to the geochemical anomaly on the migrating ridge (dashed and solid curves are fitted to data with and without the Azores respectively; see text for empirical relationships). Residual elevation ΔE is the maximum elevation observed along the geochemical anomaly above the 2,900 m-depth base line of normal ridge axes adopted from ref. 26 (that is, ridge segments not influenced by hotspots and without any geochemical anomalies). All values used are listed in Table 1.

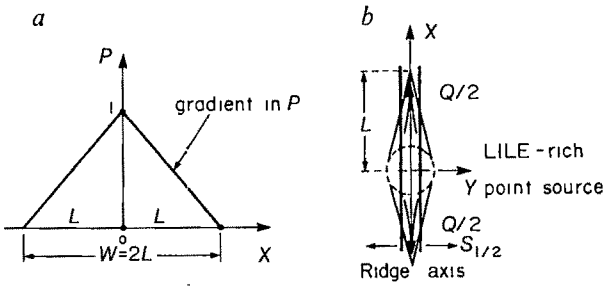

Fig. 4 *a*, Steady state, subcrustal ridge-centred mantle-plume flow model considered in text. Diamond-like figure delineates idealized boundary of plume flow which along x feeds in part of the spreading ridge axis (heavy parallel line) with LILE-rich material. *b*, Corresponding variation with x of the fraction (P) of LILE-rich plume material entering the mix with LILE-depleted asthenosphere to form the new oceanic lithosphere. The two vectors represent integrated plume flux $Q/2$ along the x direction when a steady state is reached with new lithosphere formation by spreading along the ridge axis (sink).

Finally, I note that Vogt[26] has modelled independently fluxes for along-ridge subcrustal pipe flows from hotspots on the basis of topographic gradients. These fluxes[26] should not be confused with the flux in my equation (1) which refers only to material with plume signature. The latter could be only a fraction of the total flux taking place along the ridge proposed by Vogt's model[26].

Off-ridge hotspot case. I can now extend the steady-state, ridge-centred hotspot model to the situation where there are fixed off-ridge hotspot sources but migrating ridges. Here the flux Q represents the rate at which plume material is being discharged at the mouth of the lateral channel connecting the off-ridge hotspot to the migrating ridge. I refer to this discharge flux as Q_d. Any excess of plume-derived material would be deflected along the ridge axes on either side of this intersection and be used up progressively by the accreting process. As I have determined empirically that W is related inversely to the distance of the ridge to the hotspot (y) (or inversely related to the time (t) elapsed since the migrating ridge was over the hotspot), it follows from equation (3) that the Q_d of plume-related material reaching the migrating ridge may, to a first approximation, be related inversely to the distance y ($Q_d \propto 1/y$) (or inversely related to t). In other words, the amount of plume material (or mixture of plume and asthenospheric materials) reaching the migrating ridge should decrease progressively with time and as the migrating ridge becomes more distant from the hotspot, until it becomes essentially intraplate. Eventually, our steady-state model will no longer apply because of the lack of excess plume flow; only a trickling of plume material will reach the ridge with very inefficient mixing[15]. Here, (for example, St Helena) W may only approximate the width of the lateral connecting channel. Of course, I do not suggest that by combining all the hotspot-migrating ridges so far studied, an inverse relationship should exist between the plume discharge rates Q_d and y or t. This stems from the fact that the blob size and total plume flux Q may vary from one hotspot to another, or with time for a single hotspot. As I have noted previously, the spreading-rate variation with x, which may also affect $H(x)$, will differ from one hotspot–ridge system to another.

Flow pattern

Two simple types of arguments provide additional support for suggesting in plan form in the upper mantle a relatively narrow flow channel from the off-ridge hotspot to the migrating ridge.

The first method is based on the comparison of the spatial geochemical variation and derived P values observed with those predicted in plan form from a radially zoned mantle-plume flow tapped passively by the migrating ridge (Fig. 5*a*). This approach is particularly amenable to tests if large fracture zone offsets are present, for example, the Galapagos[12–13], thus causing major discontinuities in distances from the ridge axis to the hotspot and predicting discontinuities in the geochemical variations and related P values. Here, it was shown geochemically that such a radially zoned plume flow model is not viable; instead, a northward channelled plume flow toward the ridge is more appropriate, as suggested independently by Morgan[11] on the basis of constructional volcanism and plate kinematics. The same kind of argument can be used for the Tristan configuration, where the Mid-Atlantic Ridge stations located nearest to the Tristan hotspot are not the most enriched in La/Sm (Fig. 1). This test, however, becomes more difficult to apply to the case of the most distant St Helena, Circe and Great Meteor hotspots, because of the large local dispersion and poor mixing conditions observed in the related along-ridge geochemical anomalies and the lack of major ridge offsets along these segments.

In the second type of test, I consider only the variation of W with t or y to the hotspot, regardless of the form of the variation $P(x)$ in the anomaly (Fig. 5*b*, *c*). Figure 5*b* shows again a model which considers in plan form an outward radial plume flow, extending to a radius R and its passive tapping by the migrating ridge above. The radial variation of the P value need not be specified. The circumference limit at R can be considered physically either as the location where the plume is so diluted with

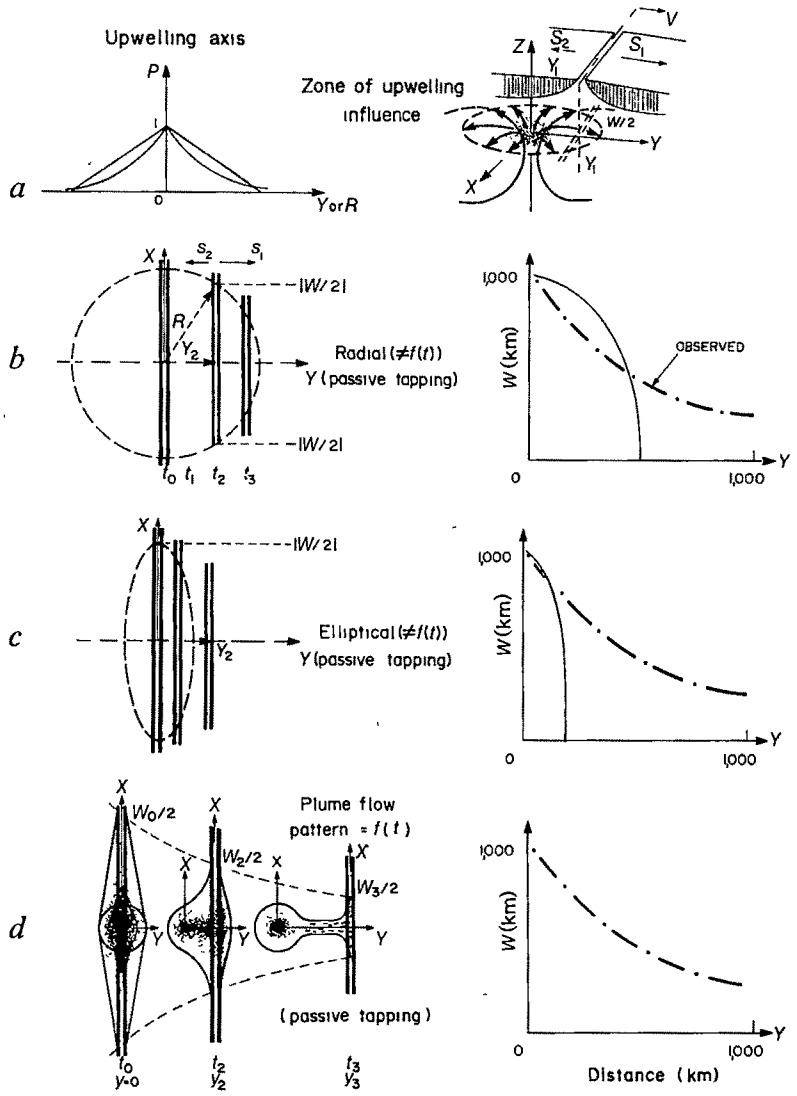

Fig. 5 Models of plume-flow (source) migrating ridge (sink): The vectors S_1 and S_2 are the half-spreading rates relative to the ridge axis; V is the component of the absolute motion of the migrating ridge along the spreading direction and relative to the hotspot which is considered fixed in space. The mixing fraction P of LILE-rich material is specified only in model *a*, where it decreases regularly outward from the centre of the plume. In model *b*, the zone of plume influence detected and passively tapped by the migrating ridge is circular and independent of time, whereas in *c* it is elliptical. Both models *a* and *b* predict a variation of W on the ridge with y which is concave downward, instead of upward as observed empirically in Fig. 2. Model *d* considers a plume-flow pattern variable in time and influenced by the migrating ridge, hence changing pressure gradients. The plume-flow configuration is shown for three different times. At t_0, the plume is ridge-centred, the ridge is elevated anomalously, the plume flow is mostly along the x-axis, and P varies regularly with x (same model as in Fig. 4, for example, Iceland). At time t_3, the plume flow is now channelled toward the more distant ridge, W on the ridge is minimal and the elevation is now essentially normal, mixing is irregular and the heterogeneities are schlieren-like (for example, St Helena-Mid Atlantic Ridge). At time t_2, an intermediate case, the plume flow is skewed both toward and along the migrating ridge which acts as a sink (for example, Galapagos).

the depleted asthenosphere that it can no longer be detected or that the radial plume panache is returning down into the mantle and at the radius R the return flow is deeper than the partial melting zone where lavas used in the sampling take source (Fig. 5*b*). As the ridge is migrating along the y direction over the zone of influence of the plume (that is, when $y < R$), the length of the ridge over which material with plume signature can be detected (that is, W) decreases as expected from the empirical relations established in Fig. 2. The predicted form of the variation of W with y, however, is concave downward, rather than upward as actually observed. This is also the case if the zone of upwelling plume influence is elliptical as a result of initial down-flow along the ridge when it was centred over the hotspot (Fig. 5*c*). These two radial models, where the shape of the zone of plume influence in the upper mantle is considered to be essentially constant and independent of time, must therefore be rejected. A more dynamic situation is required to match the empirical variation of W with t or y (Fig. 5*d*). The plume-flow pattern about the hotspot must change with t as the plume-source/ridge-sink geometric configuration and associated resulting pressure gradients change progressively from ridge-centred to a near-ridge and finally to completely off-ridge.

We believe that the model of a highly skewed plume flow along the ridge when the hotspot was ridge-centred and the lateral flow which developed subsequently and continued to feed the plume flow along the ridge as it begins to migrate away from the hotspot, can explain satisfactorily the observed variation of W with t or y; the model is sketched in Fig. 5*d*. As long as the discharge rate at the mouth of the channel exceeds that of the accretion process per unit ridge length at this intersection, some flow will take place along the ridge and a gradient may develop if mixing conditions are regular. As the distance of the ridge to the hotspot increases with t, the plume flow along the lateral channel and the ridge axis decreases as does the width of the anomaly. The ridge crest also subsides and the mixing conditions become more irregular; considerable dilution with the surrounding depleted asthenosphere seems to occur along the channel, perhaps by entrainment and shearing associated with return flows toward the ridge in the upper mantle. Figure 5*d* illustrates how W may change with time, assuming that the empirical relationship observed from the pool of ridge-hotspot configuration so far studied is directly applicable to a single hotspot-ridge situation. W would decrease rapidly as soon as the migrating ridge leaves the hotspot and the rate of decrease slows down as y increases.

To conclude, I emphasize that, in general, the regularities observed between the geochemical and elevation anomalies along the ridge crest and their position relative to hotspots are clearly not random and are probably not coincidental. Thus, I believe that the model of hotspot-source migrating-ridge sink and a connecting flow channel deserves further consideration and testing. The regularities noted should also be taken into consideration by proponents of the alternative stochastic plum-pudding model[4,5]. With these modifications, these two extreme models need not be necessarily mutually exclusive.

I thank R. Kingsley, B. McCully and G. Bode for assistance in the preparation of this work, F. DiMeglio and his staff for neutron activation and facilities at the Rhode Island Nuclear Science Center and S.-S. Sun for a helpful review. Financial support was provided by NSF.

Hypervariable 'minisatellite' regions in human DNA

Alec J. Jeffreys*, Victoria Wilson* & Swee Lay Thein†

* Department of Genetics, University of Leicester, University Road, Leicester LE1 7RH, UK
† MRC Molecular Haematology Unit, Nuffield Department of Clinical Medicine, John Radcliffe Hospital, Headington, Oxford OX3 9DU, UK

The human genome contains many dispersed tandem-repetitive 'minisatellite' regions detected via a shared 10–15-base pair 'core' sequence similar to the generalized recombination signal (χ) of Escherichia coli. *Many minisatellites are highly polymorphic due to allelic variation in repeat copy number in the minisatellite. A probe based on a tandem-repeat of the core sequence can detect many highly variable loci simultaneously and can provide an individual-specific DNA 'fingerprint' of general use in human genetic analysis.*

DNA POLYMORPHISMS have revolutionized human genetic analysis and have found general use in antenatal diagnosis[1], mapping of human linkage groups[2,3], indirect localization of genetic disease loci by linkage[2,4,5] and analysis of the role of mitotic nondisjunction and recombination in inherited cancer[6–9]. Single-copy human DNA probes are used normally to detect restriction fragment length polymorphisms (RFLPs), most of which result from small-scale changes in DNA, usually base substitutions, which create or destroy specific restriction endonuclease cleavage sites[10,11]. As the mean heterozygosity of human DNA is low (~0.001 per base pair)[10–12], few if any restriction endonucleases will detect a RFLP at a given locus, although the probability of detection is improved for enzymes such as *Msp*I and *Taq*YI which contain the mutable CpG doublet in their recognition sequence[13]. Even when detected, most RFLPs are only dimorphic (presence or absence of a restriction endonuclease cleavage site) with a heterozygosity, determined by allele frequencies, which can never exceed 50% and which is usually much less. As a result, all such RFLPs will be uninformative in pedigree analysis whenever critical individuals are homozygous.

Genetic analysis in man could be simplified considerably by the availability of probes for hypervariable regions of human DNA showing multiallelic variation and correspondingly high heterozygosities. The first such region was isolated by chance by Wyman and White[14] from a library of random segments of human DNA. The structural basis for multiallelic variation at this locus is not yet known. Subsequently, and again by chance, several other highly variable regions have been discovered near the human insulin gene[15], α-related globin genes[16–18] and the c-Ha-*ras*-1 oncogene[19]. In each case, the variable region consists of tandem repeats of a short sequence (or 'minisatellite') and polymorphism results from allelic differences in the number of repeats, arising presumably by mitotic or meiotic unequal exchanges or by DNA slippage during replication. The resulting minisatellite length variation can be detected using any restriction endonuclease which does not cleave the repeat unit and provides for such loci a set of stably inherited genetic markers.

We have described previously a short minisatellite comprised of four tandem repeats of a 33-base pair (bp) sequence in an intron of the human myoglobin gene (ref. 20; Fig. 1). The 33-bp repeat showed some similarity in sequence to three other hypervariable human minisatellites characterized previously and on the basis that the myoglobin minisatellite was flanked by a 9-bp direct repeat characteristic of the target site duplications generated by transposable elements, we suggested that this minisatellite and some other hypervariable regions were related via transposition. We show here that the myoglobin 33-bp repeat is indeed capable of detecting other human minisatellites, some of which are highly polymorphic. These regions, however, are not related by transposition, but instead share a common short 'core' sequence in each repeat unit, which in turn provides a powerful probe for hypervariable regions.

Probe for variable human DNA

A pure repeat probe was prepared from the human myoglobin minisatellite by purification of a single 33-bp repeat element followed by head-to-tail ligation and cloning of the resulting polymer into pUC 13 (ref. 21; Fig. 1). Cleavage of one of the resulting recombinants, pAV33.7, with *Bam*HI plus *Eco*RI released a 767-bp DNA insert comprised almost entirely of 23 repeats of the 33-bp sequence.

Low stringency hybridization of this repetitive insert to human DNA digested with restriction endonuclease *Eco*RI detected numerous cross-hybridizing DNA fragments, some of which showed signs of polymorphic variation (data not shown). To improve the detection of polymorphisms, the hybridization was repeated with human DNA digested with *Hin*fI or *Hae*III, both of which cleave at a 4-bp sequence not present in the 33-bp repeat sequence and which should release minisatellites in relatively small DNA fragments whose size will reflect more closely the number of repeats per minisatellite. As shown in Fig. 2, the repetitive probe detected multiple DNA fragments in human DNA as well as the parent DNA fragment from the human myoglobin gene. The larger DNA fragments (in the range 2–6 kilobases (kb) and substantially larger than the mean DNA fragment size of ~0.3 kb in human DNA digested with *Hin*fI or *Hae*III) in particular showed variation between the three individuals examined; these variants were transmitted apparently in a Mendelian fashion, in that each polymorphic

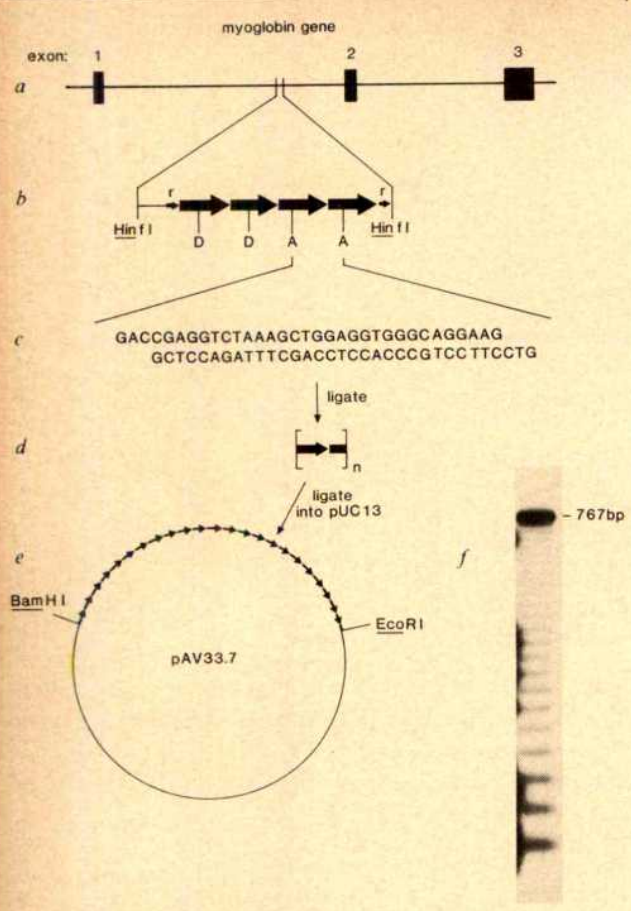

Fig. 1 Construction of a tandem-repetitive hybridization probe for 33-related DNA sequences. *a*, *b*, This probe was derived from a tandem repetitive segment of the human myoglobin gene[20]. This region, located in the first intron and comprising four repeats of a 33-bp sequence flanked by a 9-bp direct repeat (r), was isolated in a 169-bp *Hin*fI fragment, end-repaired and amplified by cloning into the *Sma*I site of pUC13 (ref. 21). *c*, A 33-bp repeat monomer was isolated by cleaving the third and fourth repeat with *Ava*II (A); a single base substitution in repeats 1 and 2 eliminates this site and creates instead a *Dde*I (D) cleavage site[20]. *d*, Ligation of the 33-bp monomer via the non-identical *Ava*II sticky ends produced a head-to-tail polymer. Polymers containing ⩾10 repeats were isolated by preparative agarose gel electrophoresis[33], end-repaired, ligated into the *Sma*I site of pUC13 and cloned in *E. coli* JM83 (ref. 21). *e*, The structure of clone pAV33.7 was confirmed by excision of the insert at the polylinker with *Bam*HI plus *Eco*RI, fill-in labelling with α-^{32}P-dCTP at the *Bam*HI site, and partial digestion with *Ava*II. *f*, Labelled partial digest products were resolved by electrophoresis on a 2% agarose gel. pAV33.7 contains 23 repeats of the 33-bp monomer contained in a 767-bp *Bam*HI/*Eco*RI fragment as shown (*e*).

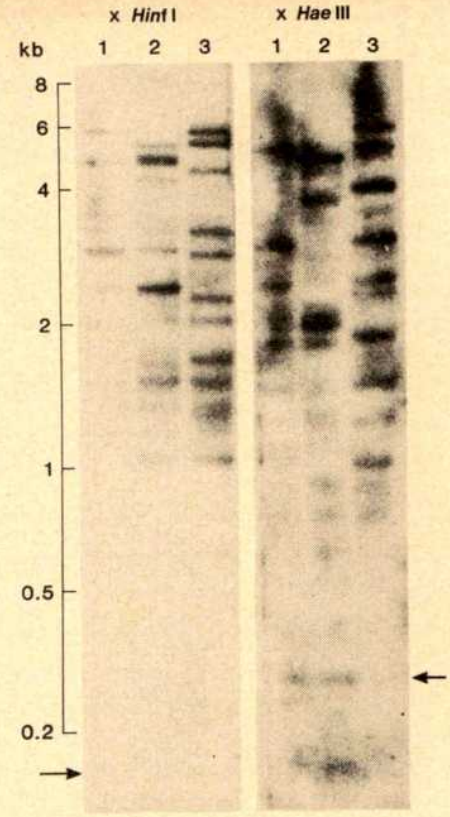

Fig. 2 Detection of multiple 33-related sequences in human DNA. 10 μg samples of DNA from individual 1 (daughter), 2 (mother) and 3 (father) were digested with *Hin*fI or *Hae*III, electrophoresed through a 1% agarose gel and transferred by blotting[35] to a Pall Biodyne membrane to prevent the loss of small DNA fragments. The membrane was hybridized in 1×SSC at 60° with dextran sulphate[36] to the insert from pAV33.7 (Fig. 1) labelled *in vitro* with ^{32}P (ref. 20). The arrowed fragment in each digest is derived from the minisatellite located in the myoglobin gene (Fig. 1); a survey of DNA from 12 individuals digested with *Hae*III showed that this myoglobin minisatellite is monomorphic (data not shown).

band in the daughter could be identified within one or other (but not both) parents. Variation was detectable in both *Hin*fI and *Hae*III digests of human DNA, consistent with polymorphism resulting from length variation of minisatellite regions.

Isolation of minisatellites

A human genomic library[20] of 10–20 kb *Sau*3A partials of human DNA cloned in phage λL47.1 (ref. 22) was screened by hybridization with the 33-bp repeat probe from pAV33.7. At least 40 strongly-to-weakly hybridizing plaques were identified in a library of 3×10^5 recombinants, consistent with the complexity of the Southern blot hybridization (Fig. 2). A random selection of eight of these positive plaques was purified (λ33.1–15) and Southern blot analysis of phage DNA showed that in each recombinant the hybridizing DNA was localized in a unique short (0.2–2 kb) region of the recombinant. Sequence analysis (Fig. 3) showed that this region in each of the eight recombinants contains a minisatellite of 3–29 tandem copies of a repeat sequence whose length ranged from 16 bp in λ33.15 to 64 bp in λ33.4. Most minisatellites contained an integral number of repeats. In λ33.6, the 37-bp repeat consisted in turn of a diverged trimer of a basic 12-bp unit. Each λ33 recombinant represented a different region of the human genome, judged by the clone-specific DNA sequences flanking each minisatellite.

Highly polymorphic minisatellites

The eight cloned minisatellite regions were located in 0.5–2.2-kb *Hin*fI DNA fragments, smaller than the clearly polymorphic 2–6-kb DNA fragments detected by pAV33.7 in *Hin*fI digests of human DNA (Fig. 2). To determine whether any of the cloned regions were also polymorphic, ^{32}P-labelled single-stranded DNA probes were prepared from suitable M13 subclones of each minisatellite and hybridized at high stringency to a panel of 14 unrelated British caucasian DNAs digested with *Hin*fI. Typical hybridization patterns are shown in Fig. 5, showing that under these hybridization conditions each probe detects a unique region of the human genome. Alleles detected by each probe are summarized in Table 1 where in each case, the most common *Hin*fI allele corresponded in size to the *Hin*fI minisatellite fragment in clones λ33.1–15, suggesting that these regions have been isolated without major rearrangement.

In the limited population sample studied, four of the eight minisatellites showed polymorphic variation. Three of the regions were highly polymorphic with between five and eight resolvable *Hin*fI fragment-length alleles detected per locus. This variation almost certainly results from variation in the repeat

Table 1 Allelic variation at individual cloned minisatellites

DNA was prepared from white blood cells[10] from 14 unrelated British caucasians (seven male, seven female), digested with *Hin*fI and Southern blot hybridized at very high stringency with probes from subcloned minisatellites as described in Fig. 5*a*, *b*. Cloned alleles whose sequences are shown in Fig. 3 are indicated (*). The divergence of each sequenced minisatellite from a hypothetical $(consensus)_n$ sequence is given as the mean percentage unique substitution divergence (±s.e.m.) to correct for variants which have diffused over more than one repeat. For example, λ33.15 shows 13 variants (10 substitutions and three deletions) but only five distinct variants over 29 repeats of a 16-bp sequence, giving a divergence from a $(consensus)_{29}$ sequence of $5/(29\times16) = 1.1\%$. The number of repeats in each allele was estimated from DNA fragment size; this estimate for alleles of λ33.6 is approximate (†) because of the trimeric nature of the λ33.6 repeat unit (Fig. 3). Approximate values of $\theta = 4N_eu$, where N_e is the effective population size and u is the rate of production of new length variants per locus per gamete, were estimated for each minisatellite from the number of different alleles (n_a) in the sample of 14 individuals by extensive population computer simulations designed to estimate the number of different, selectively equivalent alleles that could be maintained at steady-state in a population according to three recombinational models: A, random unequal crossing over between two alleles at meiosis, giving a new allele comprised of a random-length 5′ segment of one allele fused to random length 3′ segment of the second allele; B, constrained unequal exchange such that an allele mutates at random to gain or lose between one and three repeats; C, constrained slippage causing the gain or loss of only a single repeat. In each model, it is assumed as a first approximation that u is independent of the number of repeats in allele, as for the loci presented there is at most only a two-fold variation in allele length. Simulations were performed for values of θ from 0.1 to 100, using population sizes N_e from 50 to 500, and were continued for 10 N_e generations, steady state being achieved within $\sim N_e$ generations. Results from model A closely approximated the infinite allele model at $\theta < 2$, when the expected number of alleles n_a in a sample of i individuals is given by $n_a = \sum_1^{2i} (\theta/\theta + i - 1)$(ref. 31). Model C is the charge state model for which n_a has yet to be solved as a function of θ (ref. 32).

copy number in minisatellites, as alleles generally differed in length by an integral number of repeat units. In addition, longer alleles tended to hybridize with minisatellite probes more strongly than shorter alleles (see individual 1 in Fig. 5*a*), again suggesting that longer alleles contain more repeat sequence.

There is considerable variation in the level of repeat sequence homogeneity in each sequenced minisatellite region (Fig. 3). Some minisatellites (for example, λ33.3 and 5) show substantial repeat divergence, suggesting that these regions are not actively undergoing sequence homogenization by unequal exchange[23]; as expected, these regions show no polymorphic variation in repeat number (Table 1). Instead, the highly polymorphic minisatellites (λ33.1, 4 and 6) all show high repeat copy number together with substantial sequence homogeneity of repeats. In addition, base substitutions in the repeat units of hypervariable minisatellites tend to be present in more than one repeat (see, for example, λ33.15 in Fig. 3) which indicates that these minisatellites are actively and repeatedly engaging in unequal exchange, resulting in the diffusion of novel base substitutions across more than one repeat unit[23].

We used computer simulations to estimate the rate of unequal exchange needed to maintain the number of different (neutral) alleles (n_a) seen in our population sample (Table 1). Although space does not allow a detailed description of the population simulations, we find that for a population of N_e diploid individuals starting with a monomorphic minisatellite containing say 30 repeats, n_a reaches a steady state in $\sim N_e$ generations, the mean value of n_a being determined both by the parameter $\theta = 4N_eu$, where u is the rate of production of new length alleles per locus per gamete, and by the model of unequal exchange used in the population simulation. Three models have been investigated: (1) random meiotic unequal exchange between minisatellite alleles; (2) constrained sister chromatid exchange; (3) DNA slippage causing the gain or loss of a single repeat (Table 1, models A, B and C respectively). We favour the constrained exchange model because of the tendency for minisatellite base substitution variants to diffuse to non-adjacent repeats (Fig. 3), together with the tendency of different length alleles of minisatellites to differ from each other by several rather than either one or many repeat units (Table 1). For the highly polymorphic minisatellites, we estimate θ to be 2–6. Given that the effective population size N_e for human populations has been estimated at $\sim 10^4$ (ref. 24), this gives values of u, the mutation rate to a new length allele, of $\sim 0.5\text{–}1.5\times10^{-4}$ per gamete for a minisatellite ~1 kb long.

This value is higher than the base substitution neutral mutation rate in man, which from studies of non-coding DNA sequence divergence in man and higher primates has been

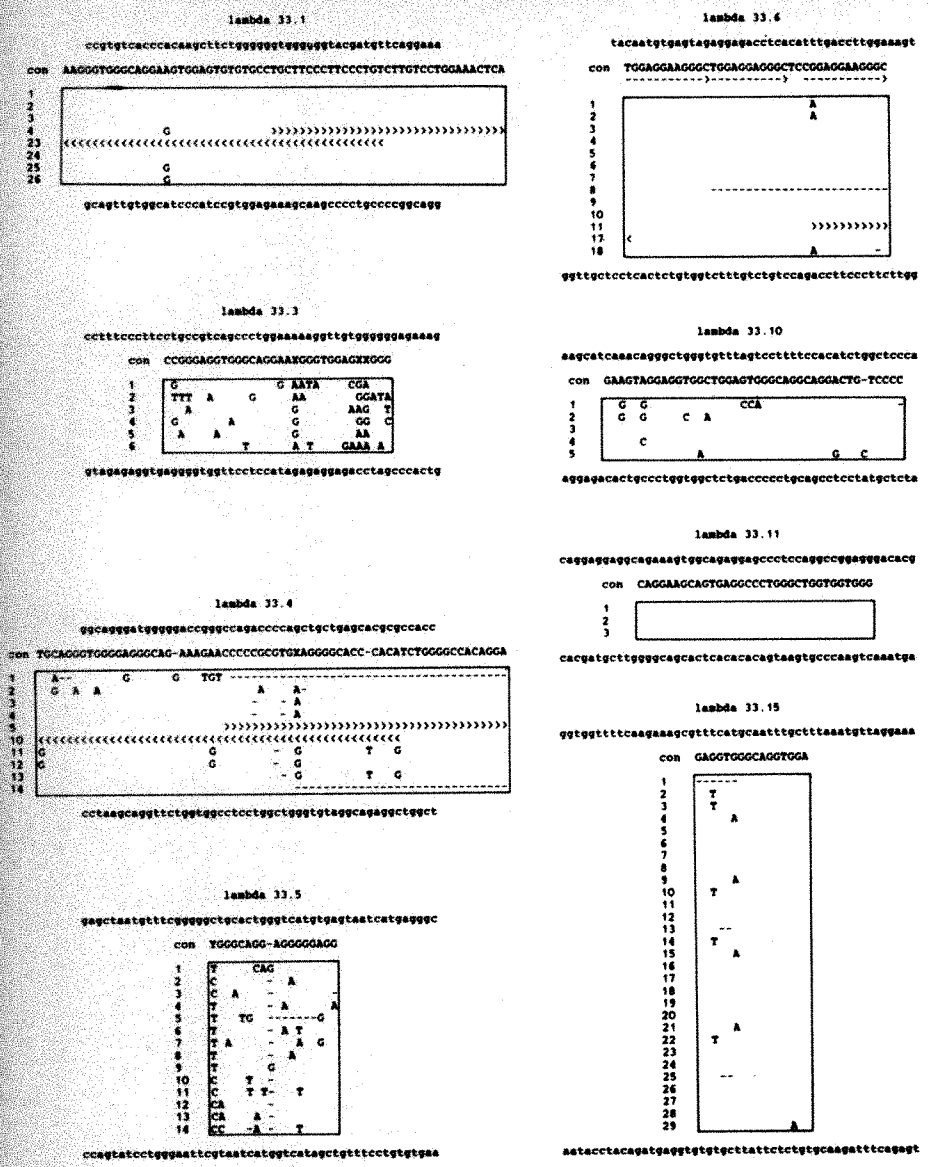

Fig. 3 Sequences of a selection of minisatellite regions detected by the myoglobin 33-repeat probe. The consensus sequence (con) of the tandem repetitive region in each of the genomic clones λ33.1–15 is shown, together with 50 bp of 5′ and 3′ flanking DNA (lower case). Differences from the consensus sequences are also shown for the individual numbered repeats (X, A or G; Y, C or T; −, missing nucleotide; »«, region not sequenced although clearly a tandem repeat of the consensus sequence, or of a close derivative of the consensus, by inspection of sequencing autoradiographs).

Methods. A library of 10–20-kb human DNA fragments cloned in bacteriophage λL47.1 (refs 20, 22) was screened by hybridization with ^{32}P-labelled pAV33.7 insert as described in Fig. 2. A random selection of eight positive plaques was purified to give recombinants λ33.1–15. Each phage DNA was digested with *Hin*fI or *Hae*III, electrophoresed through a 1.5% agarose gel, and 33-repeat related sequences localized by Southern blot hybridization with pAV33.7 DNA (Fig. 2). Each recombinant gave a single positive *Hin*fI and *Hae*III fragment, except for λ33.4 and 11 which gave no detectable positive *Hae*III fragments (because of the presence of a *Hae*III cleavage site in the repeat regions in these clones; data not shown). Suitable positive *Hin*fI and *Hae*III fragments were isolated by preparative gel electrophoresis[33], end-repaired if necessary and blunt-end ligated into the *Sma*I site of M13mp8 (ref. 37). M13 recombinants were isolated after transformation into *E. coli* JM101 and sequenced by the dideoxynucleotide chain-termination method[38,39]. Each subcloned λ33 fragment contained a tandem repetitive region which in some cases could be sequenced directly. In other cases where the repeat region was too far from the sequencing primer site, the M13 inserts were shortened by cleavage with suitable restriction endonucleases and resequenced.

estimated at 1.0×10^{-9} substitution per nucleotide site per year[25–27]. Assuming that the generation time in man is 20 yr, this predicts a base substitution mutation rate of 2×10^{-5} per 1-kb minisatellite per gamete, lower than the estimated unequal exchange rate of 10^{-4} per gamete. This disparity in rates[23] is probably sufficient to maintain the amount of repeat sequence homogeneity seen in the hypervariable minisatellites λ33.1, 4 and 6.

The rate of unequal exchange can therefore be as high as 10^{-4} per kb minisatellite sequence and presumably is proportional to minisatellite length. In contrast, the rate of homologous recombination at meiosis in human DNA is ~1 centimorgan per 10^6 bp (ref. 2) or 10^{-5} per kb. The apparently very high rate of unequal exchange in minisatellites suggests either that they are hotspots for meiotic recombination, or that most exchanges are between sister chromatids at mitosis in the germline.

A χ sequence in minisatellites?

The length and sequence of the consensus minisatellite repeat sequences vary considerably; none of them are flanked by direct repeats (Fig. 3), in contrast to the repeat region in the myoglobin gene (Fig. 1). Thus, it is unlikely that these minisatellites are related by transposition of a common ancestral sequence. We therefore used dot-matrix comparisons[28] of each minisatellite repeat consensus with the myoglobin 33-bp repeat sequence to determine which region(s) of the 33-bp repeat probe were detecting each minisatellite. Remarkably, the consensus sequence of each minisatellite repeat aligns with the myoglobin repeat specifically over a unique 10–15-bp core region of the 33-bp probe sequence (Fig. 4). This shared core region consists of an almost invariant sequence GGGCAGGAXG preceded by a 5-bp sequence common to most, but not all, repeats.

This core region in each cloned minisatellite suggests strongly that this sequence might help to generate minisatellites by promoting the initial tandem duplication of unique sequence DNA and/or by stimulating the subsequent unequal exchanges required to amplify the duplication into a minisatellite. As polymorphic minisatellites may also be recombination hotspots (see above), it might be significant that the core sequence is similar in length and in G content to the χ sequence, a signal for generalized recombination in *E. coli*[29] (Fig. 4*a*). Although the precise function of χ is unknown, current recombination models[30] suggest that this sequence binds the *rec*BC gene product, endonuclease V, which unwinds locally and nicks DNA to produce a single-stranded DNA projection required for the generation of Holliday junctions. In principle, DNA repair synthesis from the nicking site, followed by ligation to the single-stranded DNA projection, could generate a short tandem duplication with each duplicate containing a χ sequence capable of promoting unequal exchange and amplification of the duplicated region to produce a minisatellite (Fig. 4*b*). Although this model is highly speculative, it predicts that isolated core (or core-like) sequences may also be hotspots for initiating human chromosome recombination.

Probe for hypervariable regions

The repeat length of each minisatellite region is usually half (λ33.5 and 15), the same (λ33.3, 6, 10 and 11) or double the length (λ33.1 and 4) of the 33-bp probe from the human myoglobin gene (Fig. 3). This suggests that detection of minisatellites by pAV33.7 depends not only on the presence of a core sequence in each repeat but also on an in-phase alignment of cross-hybridizable core sequences in a heteroduplex between a minisatellite and the 33-bp repeat probe. If this is correct, then a probe consisting only of a tandem-repeated core sequence should be able to detect not only the human DNA fragments detectable by pAV33.7, but also additional minisatellites incapable of forming stable heteroduplexes with the 33-bp repeat probe. We therefore used the minisatellite from λ33.15, comprising 29 almost identical repeats of an almost perfect 16-bp core sequence, as a hybridization probe for additional minisatellites.

As shown in Fig. 5, this repeated core probe detects a complex profile of hybridizing fragments in human DNA digested with *Hin*fI, including most, but not all, of the bands detected previously with the 33-bp repeat probe from pAV33.7 (comparative data not shown). Only the largest (4–20 kb) *Hin*fI fragments can be resolved fully; these show extreme polymorphism to the extent that the hybridization profile provides an individual-specific DNA 'fingerprint'. Large fragment hyperpolymorphism is to be expected as, if the rate of unequal exchange is proportional to minisatellite length, then long minisatellites (~10 kb long) will have a greater unequal exchange rate ($u \sim 0.001$), raising both the heterozygosity and the number of alleles in a population.

Pedigree analysis

To establish that these large highly polymorphic fragments are stably inherited and segregate in a mendelian fashion, we analysed *Hin*fI digests of DNAs taken from an extensive Asian-Indian pedigree of Gujerati origin, including 54 individuals spanning four generations. The Southern blot/gel electrophoresis time was increased to improve the resolution of these large fragments. Typical examples of part of this pedigree are shown in Fig. 5*d*, *e*, confirming that the polymorphic variation is so great that all individuals, even in a single sibship of a first-cousin marriage (Fig. 5*e*), can be distinguished.

The families in Fig. 5*d*, *e* show that most of the large *Hin*fI fragments are transmitted from each parent to only some of the offspring, establishing that most of these fragments are present in the heterozygous state and that the heterozygosity for these large hypervariable fragments must be approaching 100%. Furthermore, inheritance is Mendelian in that these heterozygous bands are transmitted on average to 50% of the offspring; 48 clearly-resolved different heterozygous parental bands were scored in four sibships of 4–6 individuals and gave a total of 116 cases in which an offspring had inherited a given parental band, compared with 124 cases where the band had not been transmitted (data not shown). Conversely, all fragments in offspring can be traced back to one or other parent, then in turn to their parents (with one exception, see below) and therefore provide a set of stably inherited genetic markers. No band is specifically transmitted from father to son or father to daughter (Fig. 5*d*), eliminating Y and X linkage respectively and implying that these minisatellite fragments are mainly autosomal in origin. Although it is not yet known from where in the set of autosomes these DNA fragments originate, they are not derived from a single localized region of one autosome. Instead, pairs of parental fragments can be identified which segregate independently in the offspring (Fig. 5*d*). Precisely, a pair of bands AB in one parent (and absent from the other) cannot be allelic, nor linked closely in repulsion, if there is at least one AB or − − offspring; the presence of A− or −B recombinant progeny further establishes lack of tight linkage in coupling between A and B. Careful examination of the original autoradiograph of the family shown in Fig. 5*d* reveals, by these criteria, at least 10 resolvable bands in the mother, eight of which are mutually non-allelic and not linked closely. Two other bands may each be an allele of one of the eight unlinked fragments, in that only A− and −B progeny are observed in the limited number of offspring analysed, although such a small sample is insufficient to prove that such pairs of fragments are alleles of a single locus. We conclude that the core probe can give useful information simultaneously on at least several distinct unlinked hypervariable loci.

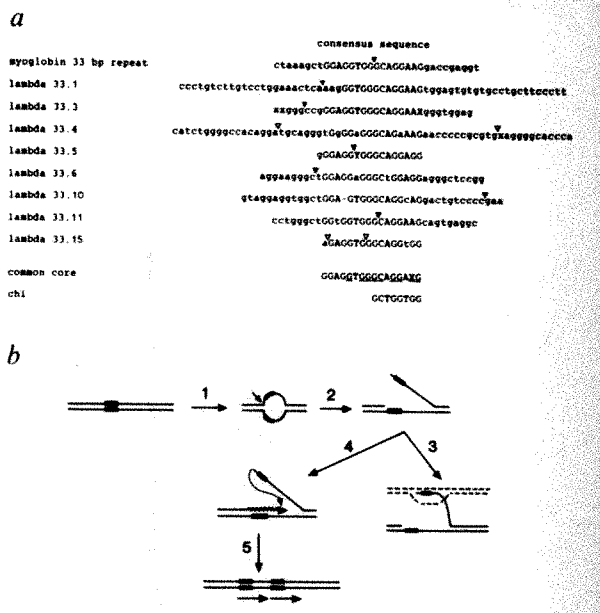

Fig. 4 A common χ-like core sequence shared by the repeat sequence of each minisatellite region. The sequence of each region was compared with the 33-bp tandem repetitive sequence in pAV33.7 and with its reverse complement, using dot-matrix analysis with variable windows and matching criteria[28]. In each case, only a single unambiguous region of sequence similarity was found between the myoglobin 33-bp repeat sequence and the λ33-repeat sequence. The same region was shared by the repeats of all eight λ33 clones. *a*, The aligned sequence of each repeat consensus, each of which is given as an arbitrary cyclic permutation of the consensus shown in Fig. 3. The common core sequence shared by all repeats is also shown and positions in each consensus which conform to the core sequence are identified by upper case letters. Invariant nucleotides in the canonical core sequence are underlined; the generalized recombination signal (χ) of *E. coli* is given also[29]. The beginning/end point of each repeat consensus (Fig. 3) is identified by ▼; in the case of λ33.4 and λ33.15, there is a non-integral number of repeats (Fig. 3) and the separate repeat beginning and end points are shown by ▽. *b*, Model for minisatellite generation promoted by χ-like sequences. (1) A χ-like region denoted by a box. RecBC enzyme binds to χ and unwinds DNA. (2) Nicking produces a single-strand projection (3), which can be assimilated into a homologous duplex to form the precursor of a Holliday junction[30]. (4) Alternatively, DNA repair synthesis followed by (5) ligation and segregation produces a tandem duplication of a χ-containing sequence which can amplify further by unequal exchange. The length of the tandem repeat is determined by the extent of repair synthesis.

A new mutant allele

The extreme variability of the large *Hin*fI DNA fragments detected by the repeat core sequence suggests that the rate of generation of new length alleles must be very high and possibly amenable to direct measurement. There is a clear instance of a new mutation in the pedigree shown in Fig. 5*e*; individual 17 has a new fragment (arrowed), not present in either parent, which might have been derived by unequal exchange and slight expansion of a smaller maternal and paternal fragment present in the other offspring. In a survey of 27 individuals and their parents (data to be presented elsewhere), 240 clearly resolved offspring bands could be traced to one or other parent, the only exception being the band in individual 17. This gives a mutation rate u to a new allele for these hypervariable fragments of

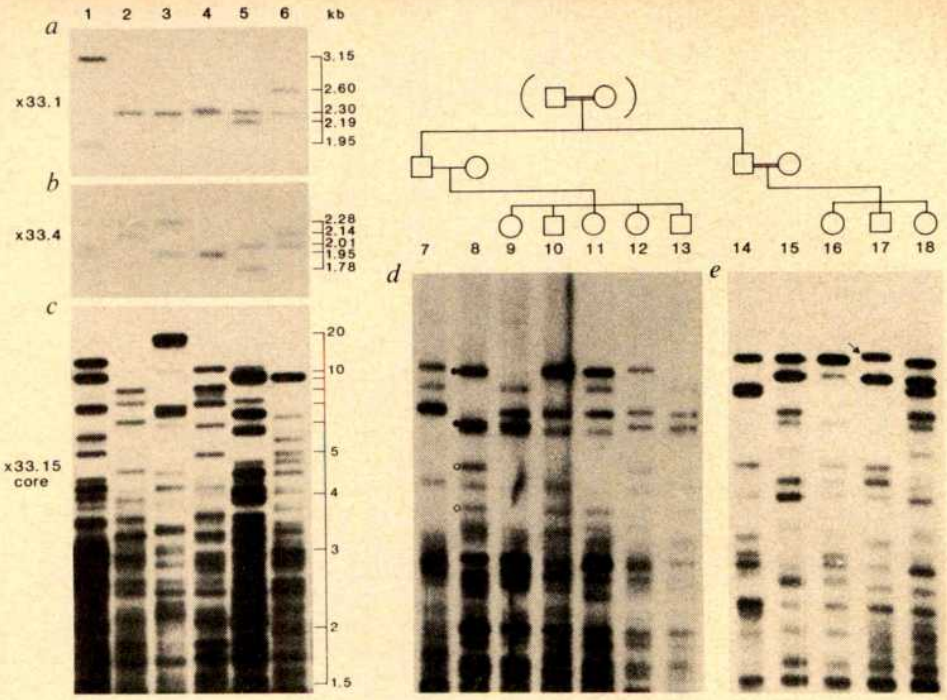

Fig. 5 Polymorphic human DNA fragments detected by hybridization with individual λ33 probes. Southern blots of *Hin*fI digests of DNA from a random sample of British caucasians (1–6) and from selected members of a large British Asian-Indian pedigree (7–18) were hybridized with single-stranded ^{32}P-labelled hybridization probes prepared from suitable M13 recombinants containing minisatellite regions. The pair of bands (○) in individual 8 is an example of non-allelic fragments which are not tightly linked; the pair marked (●) illustrates possible allelism in that each of the five offspring inherits only one of the two fragments. The arrowed fragment in individual 17 is present in neither parent and is a new mutant. The correct paternity of individual 17 has been verified as described below.

Methods. 10 μg samples of DNA prepared from white blood cells[10] were digested with *Hin*fI, electrophoresed through a 20-cm long 1% agarose gel and transferred by blotting to a Sartorius nitrocellulose filter. Single-stranded ^{32}P-labelled hybridization probes were prepared from M13 recombinants as follows. Approximately 0.4 μg M13 single-stranded DNA was annealed with 4 ng 17-mer sequencing primer[40] in 10 μl 10 mM $MgCl_2$, 10 mM Tris-HCl (*p*H 8.0) at 60 °C for 30 min. Primer extension was performed by adding 16 μl 80 μM dATP, 80 μM dGTP 80 μM TTP, 10 mM Tris-HCl (*p*H 8.0), 0.1 mM EDTA plus 3 μl (30 μCi)[α-^{32}P]dCTP (3,000 Ci mmol^{-1}) and 1 μl 5 units μl^{-1} Klenow fragment (Boehringer) and incubating at 37 °C for 15 min. Extension was completed by adding 2.5 μl 0.5 mM dCTP and chasing at 37 °C for a further 15 min. The DNA was cleaved at a suitable restriction endonuclease site either in the insert or in the M13 polylinker distal to the insert, denatured by adding 1/10 vol. 1.5 M NaOH, 0.1 M EDTA, and the ^{32}P-labelled single-stranded DNA fragment extending from the primer was recovered by electrophoresis through a 1.5% low melting point agarose gel (Sea Plaque). The excised band (specific activity > 10^9 c.p.m. μg^{-1} DNA) was melted at 100° C in the presence of 1 mg alkali-sheared carrier human placental DNA (sheared in 0.3 M NaOH, 20 mM EDTA at 100° C for 5 min) and added directly to a pre-warmed hybridization chamber; the carrier DNA also suppressed any subsequent hybridization to repetitive DNA sequences. The precise probes used were: 33.1, a 2,000-nucleotide subcloned *Hae*III fragment containing the minisatellite plus 350-nucleotide flanking human DNA; 33.4, a 695-nucleotide non-minisatellite *Eco*RI fragment on the primer-proximal side of the minisatellite contained in a 2,015-nucleotide *Hin*fI fragment; 33.15 core, a 592-nucleotide subcloned fragment containing the minisatellite sequence plus 128-nucleotide flanking human DNA. Hybridizations were performed as described elsewhere[36], except that dextran sulphate was replaced by 6% (w/v) polyethylene glycol 6,000 (Fisons) to reduce background labelling[41]. Filters A and B were hybridized overnight in 0.5 × SSC at 65 °C and washed in 0.2 × SSC at 65 °C. Filters C–E were hybridized and washed in 1 × SSC at 65 °C. Filters were autoradiographed for 1–3 days at −80 °C using a fast tungstate intensifying screen. The correct paternity of individual 17 was established using a range of biochemical and blood group markers (haptoglobin, transferrin, red cell acid phosphatase, phosphoglucomutase I, adenylate kinase, adenosine deaminase, α_1-antitrypsin, G_c, Gm, esterase D, glyoxylase, phosphoglycollate phosphatase, C3, peptidase D, ABO, Rh and HLA; S.L.T., unpublished data), and confirmed further by rehybridizing this blot with the core minisatellite in λ33.6 to generate a second DNA 'fingerprint' in which all polymorphic bands in individual 17 could be traced back to one or other parent (data not shown).

$\sim\frac{1}{240} = 0.004$. This estimate is in reasonable agreement with the population genetic estimate of $u \sim 0.001$ for these very large hypervariable fragments (see above).

Conclusions

Here, we show not only that it is possible to design probes for the cloning of individual polymorphic minisatellite regions from human DNA, but also that the shared core sequence, which possibly serves as a recombination signal and promotes the formation of minisatellites, can be used for the simultaneous analysis of multiple hypervariable regions. We anticipate that these DNA 'fingerprints' will be of general use in human segregation analysis, in particular for detecting specific bands in close linkage with disease loci in large pedigrees and for studying marker loss in tumours. In addition, they provide a powerful method for paternity and maternity testing, can be used in forensic applications and might also be useful in detecting inbreeding between couples who have had an affected offspring possibly caused by an autosomal recessive gene carried by both parents.

The precise sequence of the core consensus shared by the repeat elements of the cloned minisatellites will be biased by the particular version of the core present in the myoglobin gene minisatellite used as the initial hybridization probe. Therefore, other variant $(core)_n$ probes might detect additional polymorphic loci not found by the λ33.15 repeated core sequence. Preliminary experiments have indeed shown that the core minisatellites in λ33.5 and λ33.6 also hybridize to multiple hypervariable loci, many of which are novel. We are attempting currently to clone large hypervariable regions to provide locus-specific probes for individual minisatellites.

The detection of new mutant-length alleles of minisatellites in human pedigrees will help the analysis of rates and mechanisms of unequal exchange and gene homogenization and can in principle be used to determine whether such exchanges occur by sister chromatid exchange or by recombination between homologous chromosomes at meiosis. In addition, if the core sequence is indeed a recombination signal, then its accurate definition could provide useful substrates for studying mechanisms of human recombination.

This work is the subject of a UK Patent Application. Enquiries should be addressed to National Research Development Corporation. We thank Alain Blanchetot for a human library, John F. Y. Brookfield and Robert Semeonoff for helpful discussions and Raymond Dalgleish for advice on hybridizations. We also thank Drs D. A. Hopkinson, P. Tippett and A. Ting for analysis of various biochemical, blood group and HLA markers. Cometary impacts, molecular clouds, and the motion of the Sun perpendicular to the galactic plane

Raup and Sepkoski[1] have presented evidence from marine fossils for a 26-Myr periodicity in the occurrence of mass extinctions. Using the same data Rampino and Stothers[2] obtained a different period, 30 ± 1 Myr, which agrees with the 33 ± 3-Myr half-period for the vertical oscillation of the Solar System about the plane of the galaxy[3]. To explain this agreement they suggest[2] that encounters with molecular clouds perturb the Sun's family of comets, causing many to enter the inner Solar System where one or more collide with the Earth; the cloud encounter rate is modulated at twice the oscillation frequency, because the number density of clouds peaks at the galactic plane at the midpoint of the solar oscillation crossed by the Solar System twice per period. Notwithstanding an apparent objection to this that the most recent extinctions are not in phase with the solar oscillation[4], their model, given its stochastic nature, can accommodate a few events with large phase discrepancies. The degree of modulation is crucial: it depends on the scale height of the population of molecular clouds relative to the amplitude of the solar motion and tends to zero if this ratio is large and encounters are entirely random. Here we present data from CO surveys of molecular clouds both within and beyond the solar circle, which permit explicit calculation of the strength of the modulation. The cloud layer near the Sun is too extended and, as a consequence, the modulation of cloud encounters is too weak for a statistically significant period to be extracted from the nine extinctions analysed by Rampino and Stothers.

Although we assume a gaussian distribution of clouds with z, the distance from the galactic plane, our conclusions do not depend sensitively on this assumption and remain essentially unchanged if an exponential or other plausible distribution function is assumed instead. The empirical parameter crucial to the mechanism of Rampino and Stothers is, then, the ratio of the amplitude of the solar oscillation z_0 to the half-thickness at half-density $z_{1/2}$ of the distribution of local molecular clouds. One is not free to treat z_0 as a free parameter; it is fixed by (1) the requirement that the period, T, of the oscillation must be 60 Myr, twice the putative extinction period, (2) the circumstance that the Sun is now close to the galactic plane so its z component of velocity, $v_\perp = 7.4\ \mathrm{km\ s^{-1}}$, is essentially that at $z = 0$, and (3) the constraint of simple harmonic oscillation[5], $z_0 = v_\perp T/2\pi = 72$ pc.

Because of the large scatter and uncertainty in the distance of local clouds, there is, as yet, no reliable measurement of $z_{1/2}$ in the vicinity of the sun (that is, within ~1 kpc) from CO or other molecular cloud surveys, but there are good measurements from several large-scale CO surveys of $z_{1/2}$ as a function of galactocentric distance for distant clouds both within the solar circle and beyond. Figure 1 summarizes the survey data. All the CO surveys are consistent with a gradual increase of $z_{1/2}$ with R, proportional approximately to $R^{0.5}$ and a value of $z_{1/2}$ at the solar circle of 85 ± 20 pc (uncertainty 1 s.d.) which we will adopt here for the solar vicinity. Local observations of clouds at known distances are consistent with this value, but are inconsistent with a population of clouds significantly more compressed to the galactic plane. The well-known large concentrations of molecular clouds in Orion and Monoceros[6], for example, representing a significant fraction of local clouds by mass, lie 150-200 pc from the plane, or about twice our adopted $z_{1/2}$.

To calculate the encounter rate as the solar system oscillates sinusoidally through a gaussian distribution of clouds, we may safely neglect the small present displacement of the Sun from the galactic plane. The solar velocity components parallel and perpendicular to the plane are then $v_\parallel = v\cos b = 18.5\ \mathrm{km\ s^{-1}}$ and $v_\perp = v \sin b \sin \omega t = 7.4\ \mathrm{km\ s^{-1}} \sin \omega t$, where $v = 20\ \mathrm{km\ s^{-1}}$ is the present solar motion relative to local stars and interstellar matter[7], $b = 22°$, the galactic latitude of the solar apex[7], and $\omega_0 = 2\pi/60\ \mathrm{Myr^{-1}}$. Because of the low latitude of the apex, the solar speed as a function of time, $v(t) = v_\parallel(1 + 0.164\cos^2\omega_0 t)^{1/2} \approx v_\parallel(1 + 0.082\cos^2\omega_0 t)$, is always large with respect to the random motion of the clouds, which may be neglected. Letting $\zeta = \ln 2\ z_0^2/z_{1/2}^2$, the number of encounters (extinctions) per unit time is then simply

$$r(t) = n(z(t))v(t)\sigma = C(1 + 0.082\cos^2\omega_0 t)\exp(-\zeta\sin^2\omega_0 t) \quad (1)$$

an explicit function of time at a given ζ with no free parameters except the constant of normalization $C \equiv n_0 v_\parallel \sigma$, where n_0 is the in-plane number density of clouds and σ the encounter cross section. It is tacitly assumed that the encounters are short range, that is, that the impact parameter b is small with respect to $z_{1/2}$; the effect of long range encounters is clearly to reduce the modulation (see below).

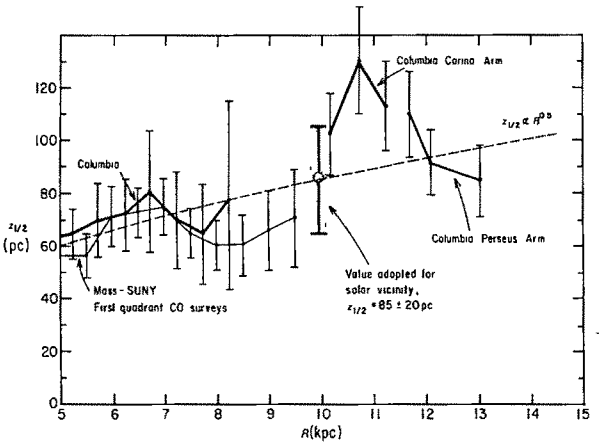

Fig. 1 Half-thickness of the distribution of molecular clouds with distance from the galactic plane, as a function of distance from the centre of the Galaxy, determined by the Massachusetts-Stony Brook (ref. 11) and Columbia CO surveys.

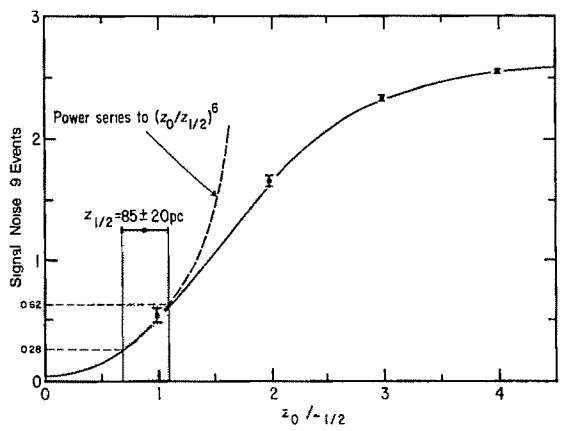

Fig. 2 Signal-to-noise of the leading Fourier component at $2\omega_0$ for nine events, as a function of the ratio of the amplitude of the solar oscillation to the half-thickness of the molecular cloud disk. The four points with vertical error bars indicate the results of a check on equation (4) with the Monte-Carlo code used to produce Fig. 3.

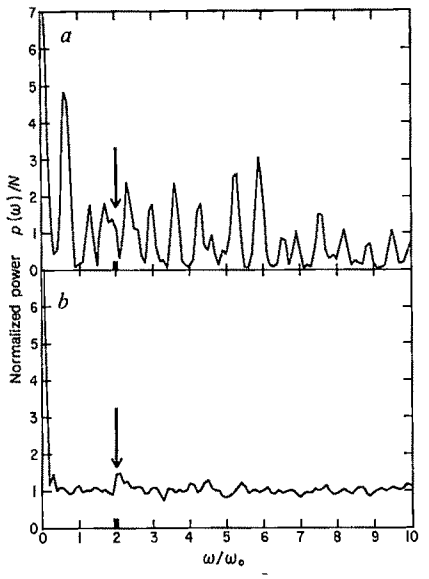

Fig. 3 Monte-Carlo calculation for $z_0/z_{1/2}=1$ of the power spectrum of random events drawn from the distribution given by equation (1). *a*, Nine events, the number of mass extinctions analysed by Rampino and Stothers[2]; *b*, the average of 100 such spectra, showing the small expectation value $\langle p(R)\rangle - \langle p(0)\rangle$ of the nine-event peak (short vertical bar at $\omega/\omega_0=2$).

We now wish to calculate the power spectrum $p(\omega)$ for a sample of N encounters drawn from this distribution with respect to time, and, specifically, the signal strength of the leading Fourier component at $2\omega_0$ relative to the shot noise, that is, the purely statistical fluctuations in the absence of modulation. We define the compex Fourier amplitude as

$$A(\omega)=\sum_{i=1}^{N}\exp(j\omega t_i)\equiv\sum_{i=1}^{N}(x_i+jy_i) \qquad (2)$$

where the t_i are the encounter times and define the power spectrum as usual as $p(\omega)=|A(\omega)|^2$. The first and second moments of $A(2\omega_0)$ are readily calculated. We may take $\langle y\rangle=0$ without loss of generality. Then, $\langle x\rangle=\int r(t)\cos 2\omega_0 t\,dt/\int r(t)\,dt\equiv R$, $\langle x^2\rangle=\int r(t)\cos^2 2\omega_0\,dt/\int r(t)\,dt\equiv S^2$ and $\langle y^2\rangle=1-S^2$, and the variances corresponding to the second moments are $\sigma_x^2=S^2-R^2$ and $\sigma_y^2=1-S^2$. The expectation value of the power at $2\omega_0$ is then

$$\langle p(R)\rangle=N^2\langle x\rangle^2+N\sigma_x^2+N^2\langle y\rangle^2+N\sigma_y^2=N(N-1)R^2+N \qquad (3)$$

Care is required in calculating the signal-to-noise ratio (S/N) as the statistical fluctuations in the absence of modulation (that is, signal) are distributed normally in A but exponentially in p; the expression for this ratio in the absence of knowledge of the phase of the signal is

$$\mathrm{S/N}=\left[\frac{\langle p(R)\rangle-\langle p(0)\rangle}{\langle p(0)\rangle}\right]^{1/2}=\sqrt{N-1}\,R \qquad (4)$$

The normalized Fourier transform R in equation (2) may be conveniently approximated analytically when ζ is not too large, by expanding the exponential in equation (1) in a power series, or it may be readily evaluated numerically at all ζ. The S/N ratio from both methods for $N=9$ events is shown in Fig. 2. For the observed thickness of the population of molecular clouds at the solar circle, S/N is evidently so small, 0.45 ± 0.17, that a statistically significant determination of the underlying modulation period cannot be obtained.

A graphic demonstration of this conclusion and a useful check as well of the analytical theory (Fig. 2), has been obtained by Monte Carlo simulation. The top of Fig. 3 shows the power spectrum derived numerically from a sample of nine random events drawn from the distribution of equation (1); the signal is clearly swamped by the purely statistical fluctuations, that is, the shot noise spikes. The expectation value of the peak power can be obtained by averaging together 100 such (independent) spectra, as in the bottom panel of Fig. 3; its smallness compared with the noise spikes in the top panel is evident. To express this result another way, scaling from equation (4) we find that even a relatively modest signal characterized by $\mathrm{S/N}=3$ would require not nine extinction events, but >300.

Given that our assumption, that the encounters between the Solar System and molecular clouds are short range with respect to $z_{1/2}$, is an oversimplification, a significantly larger number of events may actually be required. Because of the fairly flat mass spectrum of molecular clouds[8,9], the most important encounters are likely to be with large clouds or cloud complexes whose mass exceeds $1\times10^5\,M_\odot$ and these will occur mainly at impact parameters exceeding 50 pc (ref. 10). The result of such distant encounters is to increase significantly the effective thickness of the molecular cloud layer, which, by Fig. 2, further reduces the S/N ratio in the power spectrum of the peak at $2\,\omega_0$. Because of the breakdown of the impulsive approximation at large impact parameters, exactly how many additional events are required when this effect is taken into account is not clear, but we estimate that it could be a factor ≥ 10. Our conclusion is, therefore, that at least 300 mass extinctions and possibly many more, as opposed to the nine analysed by Rampino and Stothers, are required to yield statistically significant evidence for the oscillation of the Solar System about the plane of the galaxy under the molecular cloud hypothesis. It follows that if a periodicity does exist in the data, it is highly unlikely to result from encounters between the Solar System and molecular clouds.

We thank T. M. Dame, E. Gottlieb and D. A. Grabelsky for the analysis of the Columbia CO surveys. G.A.C. is an Alfred P. Sloan Research Fellow. This paper is Contribution 279 of the Columbia Astrophysics Laboratory.

The measurement of radioactivity by direct conversion of nuclear radiation into a temperature rise of a calorimeter is as old as nuclear physics itself. As part of a general programme aiming at a determination of the mass of the electron neutrino, we have designed an improved version of a He-cooled composite diamond bolometer with a monolithic germanium thermistor, developed at the Laboratoire de Physique Stellaire et Planetaire (LPSP)[1]. Our approach, based on an idea by De Rujula[2], is to study the shape, near the upper end-point of the internal bremsstrahlung spectrum in electron-capture β decay. The best nucleus for a precise measurement seems to be ^{163}Ho, for which we have determined[3] the Q_{EC} value to be 2.83 ± 0.05 keV. A particularly interesting possibility is to use total absorption spectrometry[4] (calorimetry), in which the radioactive holmium forms part of the sensitive volume of the detector. With 5–6-MeV α particles impinging on the diamond wafer of the bolometer, a full-width-at-half-maximum (FWHM) of 36 keV was obtained at a temperature of 1.3 K. The theoretical resolution at 100 mK is a few electron-volts, so this new detection technique should give greatly enhanced energy resolution compared with present solid-state conductors based on charge carrier collection.

In 1903 Curie and Laborde[5] used a calorimeter to verify that the heat produced by a radioactive substance results from the absorption of its energetic radiation. After this, microcalorimetry became of great theoretical importance through the determination[6] of the 0.337-MeV average β energy of ^{210}Bi (Ra E). In fact, the contrast between this value and the maximum β-decay energy of 1.17 MeV for ^{210}Bi was one of the key arguments which led Pauli to the hypothesis of the neutrino. Microcalorimetry finally reached a sensitivity of $\sim 3\times10^{-5}$ W at 300 K[7]. It was Simon[8] who first pointed to the possibility of nuclear micro-calorimetry at low temperatures, where heat capacities are very low; Dalmazzone[9] has investigated a calorimeter at 1.8 K and reached a sensitivity of 10^{-9} W. The idea that bolometers or thermometers at low temperature could be used as detectors for radioactivity has reappeared

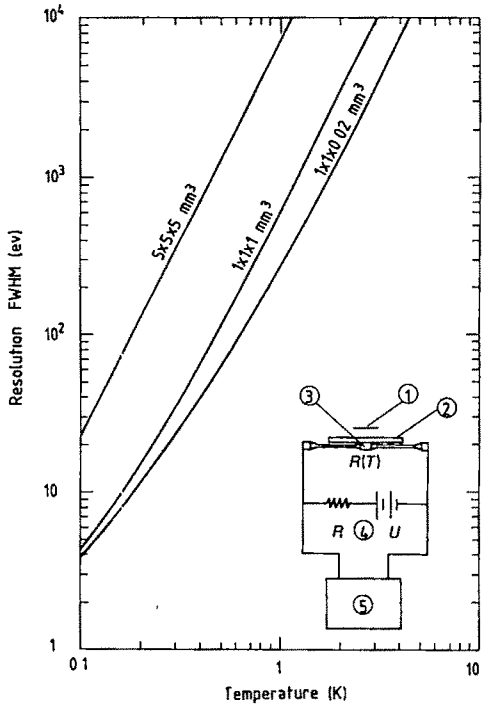

Fig. 1 Ultimate resolution with optimal filtering as a function of the temperature for the best available composite bolometer with a monolithic thermistor. The curves are calculated for three different detector volumes, V (mm^3), by means of the expression for Δv, given in the text. The 0.02-mm-thick detector represents the present technological size limit. The specific heat, C, is strongly material- and geometry-dependent and we have used the expression, $C = 7\times10^{-12}T^3 + 1.3\times10^{-12}T^{1.3} + 1.5\times10^{-12}T + 6.8\times10^{-11}VT^3$ as a good approximation to available measurements. The inset shows a schematic view of the experiment: (1) the α source; (2) the diamond substrate; (3) the Ga-doped Ge-thermistor, which also serves as mechanical support and thermal conductor to the 1.3 K thermostate; (4) the bias supply and the cooled load resistor; (5) the preamplifier–amplifier chain (at room temperature).

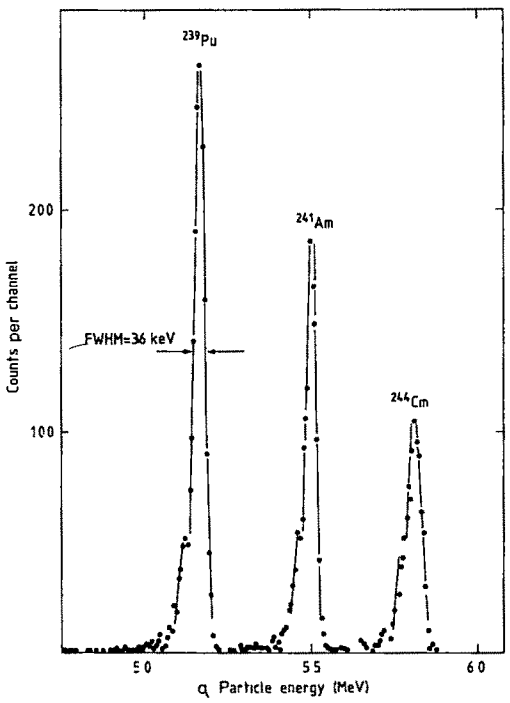

Fig. 2 Alpha energy spectrum from a mixed source of ^{239}Pu, ^{241}Am and ^{244}Cm, obtained by recording the thermal pulses induced by the α particles in a 0.25-mm^3 diamond bolometer. The resolution is 36 keV (FWHM) and the integral non-linearity is $<10^{-3}$.

recently[10-12] and it has been shown that a silicon thermistor may be used as an X-ray spectrometer[11].

The traditional use of low-temperature bolometers is for the detection of a continuous flux of infrared radiation[13-18]. The instruments based on semiconductors were found to have better performance and to be simpler to use than those based on superconductivity. The semiconductors (doped Ge or Si) have a resistance varying as T^{-4}-T^{-9} in the temperature region of 0.3-5 K. In the early 1970s a new type of bolometer, a so-called composite one, was developed at LPSP[1,14], consisting of an absorber with a large surface area (0.5-20-mm diameter) coupled thermally to a monolithic semiconductor thermistor with very small volume (typically, 0.008 mm^3). Its best performance has been obtained with a diamond wafer as the absorber and a germanium crystal as thermometer. (The use of diamond is especially advantageous because of its very high thermal diffusivity[1].) A schematic diagram of a composite bolometer is shown as an inset in Fig. 1. An asset of this construction is that there is no need for soldering, which results in a minimum of low frequency noise and a low heat capacity.

The essential advantage of the composite bolometer is that it separates the absorbing and detecting functions. The absorber (diamond, sapphire, dielectric-metal sandwich) may be optimized independently of the thermometer, which in turn has to have maximal temperature derivative of the impedance, dZ/dT, and the impedance, Z, matched to the preamplifiers[18]. The use of bolometers for detection of different kinds of flux is increasing steadily: for molecular beams[19,20], for radiation in the millimetre wave-length range[14-18] and, most recently, for X rays[11]. It is also interesting to note that spurious pulses, caused by cosmic-ray absorption in the infrared low-temperature detectors, were deliberately eliminated, using a 'spike suppression circuit', by high-altitude astronomers[21].

The diamond wafer, which acts as the absorber in our bolometer, has a volume 0.25 mm^3. At our working temperature (1.3 K) we have measured the thermalization time of the device to be <60 μs from any point of impact on its surface. The thermometer, which has a surface area of 0.1×0.1 mm^2, is glued to the diamond with a 10-μm layer of epoxy, which eliminates the possibility of charge collection, as there is no bias across the absorber.

The resolution of the detector is only limited by the noise of the detector itself (Johnson noise and thermodynamic noise) (see refs 10 and 18 for a detailed analysis of these noise effects). With optimal filtering, an order of magnitude estimate for the resolution is given by $\Delta U_{FWHM} = a\sqrt{8(\ln 2)k_B T^2 C}$ where k_B is the Boltzmann constant, T the temperature of the helium bath (in K) and C the specific heat of the bolometer at the temperature T. The constant a depends on the details of the construction of the bolometer (on dZ/dT and Z) and generally has a value of 1-2; here, $a = 1.5 \pm 0.2$. The limiting resolution calculated from this expression is shown in Fig. 1.

The bolometer used in this experiment is mounted in the vacuum chamber of a commercial portable optical cryostat[22]. A mixed ^{239}Pu, ^{241}Am, ^{244}Cm α source was positioned in front of the diamond so that no particles could reach the Ge thermometer. A Pb shutter could be inserted between source and detector during background measurements. A typical α spectrum measured at a temperature of 1.3 K is shown in Fig. 2. The low-noise preamplifier had a band pass filter of 2-120 kHz and a gain of 2,000 (ref. 23). A 5.5-MeV α particle gives a typical temperature increase of 1 mK. The resolution is 36 keV, which is not yet the best possible performance of the system. The main reason for this is that we have used standard nuclear electronics which could not be optimally matched to the time constant of the bolometer. We are presently working on improvements to both the electronics and the cryostat and hope soon to have an operational α detector with a resolution of ~3 keV at 1 K. We foresee that the technique of nuclear radiation detection via thermal pulses will have a great impact on many fields of physics.

An apparently first-order transition between two amorphous phases of ice induced by pressure

O. Mishima, L. D. Calvert & E. Whalley

Division of Chemistry,
National Research Council,
Ottawa, Canada K1A OR6

We recently reported[1] a transition from ice Ih to a high-density amorphous phase at 10 kbar, 77 K. Here we report that low-density amorphous ice (density 0.94 g cm^{-3}) compressed at 77 K transforms to high-density amorphous ice (1.19 g cm^{-3} at zero pressure) at a sharp transition at 6±0.5 kbar. The transition is at least as sharp as the previously reported[1] transition and strongly resembles a first-order transition in its sharpness and large volume change. It appears to be the first example of an apparently first-order transition between amorphous solids and has implications not only for our understanding of the behaviour of condensed matter, but also for theories of planetary interiors.

Ice Ih at 77 K, when compressed to its extrapolated melting pressure of 10 kbar, transforms very readily (in view of the temperature) to an amorphous solid of density 1.31± ~0.02 g cm^{-3} at 10 kbar and 1.17± ~0.02 g cm^{-3} at zero pressure[1]. The transformation seems to be of a new kind, in which a solid 'melts', at an apparently first-order transition well within the glass region of the liquid, to produce an amorphous phase that resembles the glass at the temperature and pressure of the experiment. When heated at zero pressure, the new phase transforms at ~117 K to an amorphous phase whose X-ray diffraction pattern resembles that of the amorphous ice made by condensing the vapour on a cold surface[2,3]. We have since determined the density of this phase, by weighing in liquid nitrogen, to be 0.94± ~0.02 g cm^{-3}.

The low-density amorphous ice would no doubt become less stable than the high-density amorphous ice it was made from, if it were put under high enough pressure. Eventually, it might transform to a high-density amorphous form resembling that made by squeezing ice I, perhaps at an apparently first-order transition resembling that of ice I[1] and, if so, its density would increase by ~23%. Such an apparently first-order transformation of one amorphous phase to another with a large increase in density seems not to have been reported, although gradual

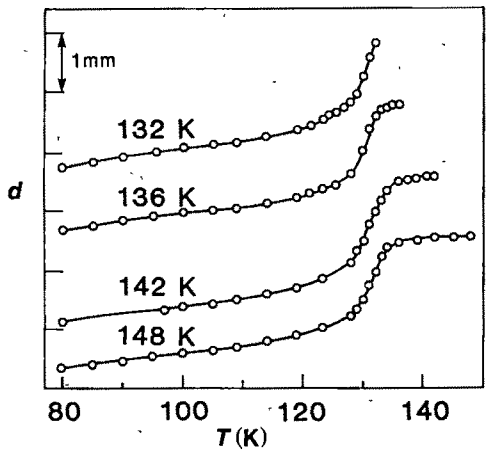

Fig. 1 The evolution of low-density amorphous ice from the high-density amorph. High-density amorphous ice was prepared by compressing about 1.0–1.2 cm^3 of water in an indium cup at 77 K to ~16 kbar in a steel vessel of 12.5 mm inside diameter, 50-mm outside diameter and 75-mm length, using a hydraulic press[1], and the pressure was reduced to a nominal pressure of 100 bar. The samples were heated in the pressure vessel at the rate of ~1 K min^{-1} to 132, 136, 142 and 148 K, as marked on the curves, and then quenched by immersing in liquid nitrogen. The temperature was measured by a thermocouple attached to the pressurizing piston and the sample may be slightly cooler than the thermocouple. The displacement of the piston is plotted against temperature in the figure.

densifications of amorphous phases of up to 20%, when squeezed to ~100 kbar with or without shearing, have been reported[4–9]. The compression of amorphous ice, reported here, should therefore be very interesting.

Four samples of high-density amorphous ice were made by compressing ice I at 77 K in an indium cup inside a steel pressure vessel[1] to ~16 kbar. The pressure was then reduced to 0.1 kbar and the pressure vessel and its contents were heated to 132, 136, 142 or 148 K at a rate of ~1 K min^{-1} to transform the high-density amorphous ice into the low-density amorph; the increase in volume was followed by the displacement of the piston. The sample was then cooled rapidly to 77 K.

The piston displacement during each of the four runs is plotted against the temperature in Fig. 1. The displacement changes rapidly with temperature above ~128 K because the high-density amorphous ice is transforming to low-density. The samples heated to 136, 142 and 148 K, which contained significantly different amounts of water, seem to have been completely transformed to the low-density form in the time of the experiment, but the sample heated to 132 K was incompletely transformed.

The low-density amorphous ice was then compressed and decompressed at 77 K in the same apparatus. The displacement of the piston during the compressions and decompressions is plotted in Fig. 2, where it is compared with the compression of a similar amount of ice Ih[1] (lowest curve). All the low-density amorphous samples compressed elastically until the sample pressure, corrected for friction, reached 6 ± ~0.5 kbar (the uncertainty is mainly due to friction in the apparatus), when a rather sudden (in view of the low temperature) transition started and the volume decreased by 4.0 ± ~0.3 cm^3 mol^{-1} or ~22%. Half of the compression occurred in a pressure range of ~0.5 kbar and the transformation seemed complete at 8–9 kbar. The transformation did not reverse when the pressure was decreased and the sample expanded only elastically. The samples that had been prepared by heating to 142 and 148 K transformed at the 6-kbar transition, but underwent another inelastic compression starting at ~10 kbar. No doubt some ice Ih[1] or Ic was formed when the samples were heated; when the samples were compressed, the ice transformed to high-density amorphous ice at 10 kbar[1], as is the case for ice Ih.

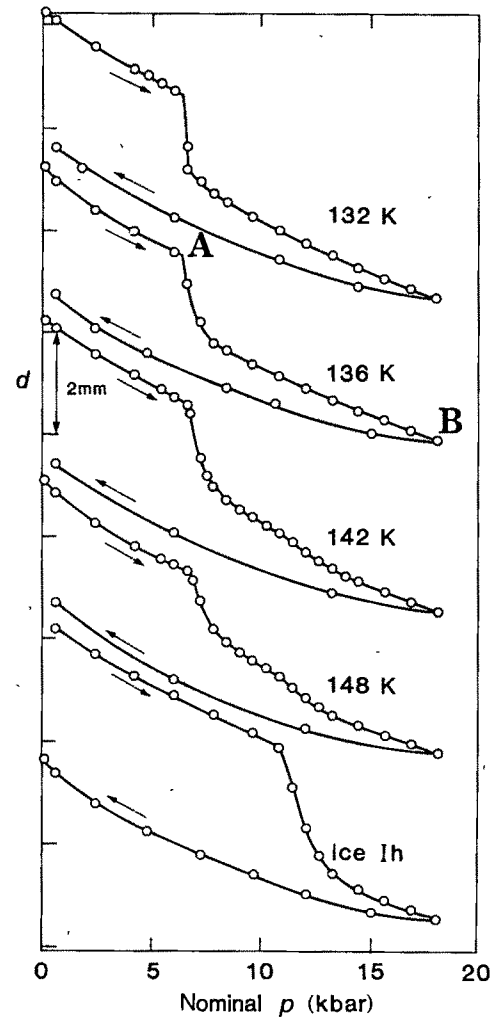

Fig. 2 Compression at 77 K to 16 kbar and decompression of the four samples of low-density amorphous ice. They were made as described in Fig. 1 legend. The arrows show the direction of the pressure changes, and the samples are identified by the temperature at which they were formed. The compression of ice Ih at 77 K is plotted as the lowest curve for comparison.

The density of the high-density phase at 6 kbar was estimated from the piston displacement to be 1.26 ± ~0.02 g cm^{-3}, and 1.19 ± ~0.02 g cm^{-3} at zero pressure. The zero-pressure density is equal, within the experimental uncertainty, to that (1.17 g cm^{-3}) of the amorph made by transforming ice Ih at 77 K and zero pressure.

Samples were recovered from the conditions represented by points A and B of the 136-K run in Fig. 2 and microphotometer traces of their X-ray diffraction patterns are reproduced in Fig. 3. The pattern of sample A is, within the experimental uncertainty, the same as that of low-density amorphous ice[1] and the pattern of sample B is the same as that of the high-density amorphous ice made by compressing ice Ih at 77 K to 10 kbar[1]. There is no doubt that the phase produced by the 6-kbar transition of low-density amorphous ice at 77 K is another amorphous phase and is similar to the high-density amorphous ice made by transforming ice I at 10 kbar[1].

The seemingly almost discontinuous transition from low-density to high-density amorphous ice with a decrease of volume of ~22% resembles, in its sharpness, the 'melting' of ice I at 77 K and 10 kbar to the 'liquid' in the glass region[1]. It seems that the low-density amorphous ice becomes unstable, relative to the high-density amorphous phase, perhaps at its surface, where ice I seems to become unstable[1], and undergoes a new kind of apparently discontinuous transition between two amorphous phases which at least approximates first-order behaviour. The phase that is produced strongly resembles the amorphous

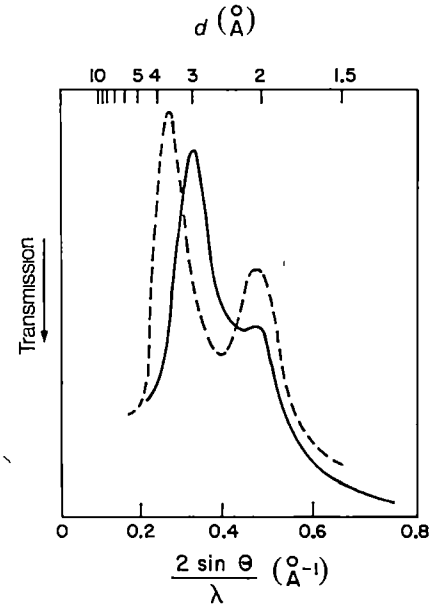

Fig. 3 Representative microphotometer tracings as a function of $(2 \sin \theta)/\lambda$, where 2θ is the scattering angle and λ, the wavelength of the X rays, of diffraction patterns of homogeneous samples of low-density amorphous ice (dashed line) and of the high-density amorphous ice (solid line) taken in a flat-plate X-ray camera. The temperature was controlled to ±5 K by flowing nitrogen gas and was measured by a thermocouple placed near the specimen. Photographs were taken at ~95 K using zirconium-filtered molybdenum radiation.

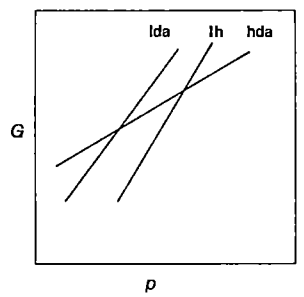

Fig. 4 Schematic graph of the Gibbs function G against the pressure p for ice Ih and low-density (lda) and high-density (hda) amorphous ice.

ice made by transforming ice I, and the transition seems to be a new way of making amorphous phases.

The pressure of the amorph–amorph transition is 4 kbar lower than that of the transition of ice I to amorphous ice at the same temperature. The difference in the transition pressures is readily understood if both transitions are considered as first-order, as they seem to be to a good approximation because they are so sharp and occur with a large volume change. The specific Gibbs functions of ice Ih, low-density amorphous ice and high-density amorphous ice are plotted schematically against the pressure in Fig. 4. From the equation $dG/dp = V$, it is readily shown that the Gibbs-function difference for two phases at zero pressure which are in equilibrium at pressure p_e is, to first order and neglecting the compressibility difference of the two phases, $\Delta G(p=0) = -\Delta V(p=0)p_e$, where ΔV is the volume difference of the two phases. The value of p_e for transformation to the high-density amorphous phase will be tentatively assumed to be the experimental transformation pressure. From the transformation pressure of ice Ih to high-density amorph[1] (hda) and of low-density (lda) to high-density amorph, and from the specific volumes of the phases at zero pressure, the Gibbs-function differences at zero pressure are $\Delta^{hda}_{Ih}G(p=0) = 4.1 \pm \sim 0.3$ and $\Delta^{hda}_{lda}G(p=0) = 2.5 \pm \sim 0.3$ kJ mol^{-1}, so that $\Delta^{lda}_{Ih}G(p=0) = 1.6 \pm \sim 0.3$ kJ mol^{-1}.

A similar transformation ought to occur in other four-coordinated amorphous solids, such as amorphous silicon and germanium. These materials crystallize when compressed at room temperature[10,11], but may form high-density amorphous phases if compressed at low temperature.

The ultimate phase of ice, as far as is known, is ice VII or VIII, both based on a body-centred-cubic arrangement of the oxygen atoms, and the corresponding phase having centrosymmetric hydrogen bonds, known as ice X[12,13]. The density of ice VIII when recovered at zero pressure and 77 K is 1.46 g cm^{-3} (ref. 14), about 25% denser than our high-density amorphous ice. The high-density amorphous ice may, therefore, undergo yet another transformation, either gradually or suddenly, if it is subjected to high enough pressures. We are presently testing this suggestion.

Finally, this amorphous–amorphous transition may be important in the planets. The ice formed in space from gaseous molecules is very probably amorphous[15] and if it agglomerates to form a planet, it will transform to the high-density amorph if the planet becomes large enough, that is, having a radius of the magnitude of 2 Mm.

We thank the National Research Council of Canada for a Research Associateship for O.M. (1983–85). This work is NRC No. 24042.

Al^{3+} coordination changes in liquid aluminosilicates under pressure

Eiji Ohtani*†, Francis Taulelle‡ & C. Austen Angell§

* Research School of Earth Sciences, Australian National University, Canberra, ACT, Australia

Geochemists often debate the conditions in which Al^{3+} may become 6-coordinated in molten silicates and how such liquid structures are related to those of coexisting crystal phases[1–4]. To date no experimental evidence for the occurrence of Al^{3+} in this coordination state has been presented and computer simulation studies have suggested that pressures exceeding 100 kbar may be required for the 4→6 conversion[5,6]. To examine this question in the laboratory, we have taken advantage of the ability of the glass transition to freeze the structural equilibrium of a high-pressure melt and preserve it for subsequent examination in ambient conditions. Glasses of albite composition have been prepared by quenching melts under pressures of 0–80 kbar (0–8 GPa). The Al^{3+} coordination has been determined by ^{27}Al solid-state NMR spectrometry. We find that the 4-coordinated state is retained to pressures well beyond 30 kbar. A new peak at −16 p.p.m. relative to $Al(H_2O)^{3+}_6$, which we associate with octahedral Al^{3+} appears weakly at 60 kbar and becomes a prominent feature of the spectrum at 80 kbar.

† Present address: Department of Earth Sciences, Faculty of Science, Ehime University, Matsuyama, 790 Japan
§ Permanent address: Department of Chemistry, Purdue University, West Lafayette, Indiana 47907, USA.

Before proceeding, we should point out that the 'fluctuations' about the average structure, which are characteristic of the liquid state, are also preserved during the high-pressure quench. This means that ambient pressure studies of the glass by small angle X-ray scattering[7], or by equivalent techniques[8], may yield another quantity much sought by geochemists, namely, the liquid silicate compressibility, κ_T. This is because frozen-in density fluctuations $\Delta\rho$, rather than composition fluctuations Δc, will in general dominate the scattering[9]. The compressibility is obtained via the well-known statistical thermodynamic relation, $\kappa_T = -\langle\Delta\rho\rangle^2 V_m/\rho^2 RT$ (ref. 10) and we hope to report such measurements soon.

For this study, albite was synthesized by heating the mixture of reagents Na_2CO_3, $SiO_2 \cdot x(H_2O)$, and $Al_2O_3 \cdot x(H_2O)$, at 1,100 °C for 20 h at 1 atm. The sample was ascertained to be a pure single phase of albite by means of X-ray diffraction. Glass samples were synthesized at various pressures of 1 atm, 20, 30, 60 and 80 kbar. The glass sample at 1 atm was prepared by heating the crystalline albite at 1,350 °C for 30 min and by quenching with a cooling rate $\sim 10^3$ deg s^{-1}.

A piston-cylinder apparatus was used to synthesize albite glass at pressures of 20 and 30 kbar. Graphite was used for the furnace material and a Pt/(Pt+10% Rh) thermocouple was used to measure the temperature. Crystalline albite, which was inserted into a Pt capsule, was heated to 1,500 °C at 20 kbar and to 1,600 °C at 30 kbar for 5 min, and glass was obtained by quenching the charge isobarically by switching off the heater power. The cooling rate was estimated to be $\sim 0.5\text{-}1 \times 10^3$ deg s^{-1}.

Glass samples at pressures of 60 and 80 kbar were synthesized using a multiple-anvil high-pressure apparatus recently constructed at the Australian National University, the details of which are given elsewhere[11]. The heater material was again graphite, and a (W+5% Re)/(W+25% Re) thermocouple was used to measure the temperature. Crystalline albite, added to graphite or boron nitride capsules, was heated above the melting temperature (1,650-1,850°C at 60 kbar, ~2,000 °C at 80 kbar) for about 1-2 min, after which the charge was quenched by cutting the power as before The cooling rate was estimated to be $\sim 1\text{-}10 \times 10^3$ deg s^{-1}. The melting periods used should be well in excess of those needed to obtain structural equilibrium in a melt formed from a single-phase solid in which only local relaxation occurs on melting. Even at the glass transition temperature T_g, the structural relaxation time (which scales with the viscosity) is ~1 min[12] and, at its melting point, the viscosity of albite is six orders of magnitude less than it is at T_g. (Some highly viscous melts nevertheless seem to retain some memory of the crystal structure from which they are derived insofar as they nucleate the parent crystal more easily than expected from long-time melting data, though we have no evidence for this in the present case.)

Despite the higher cooling rates for the high-pressure samples, it was difficult to avoid crystallization completely in the latter cases. Crystallized regions containing jadeite occurred at the sample ends where the cooling rate was smallest. These were identified under the microscope and removed before spectra were taken. One sample was deliberately crystallized to obtain a jadeite (6-coordinated Al) standard.

Because the volume of sample obtainable at 60 and 80 kbar was so small, the products of three separate preparations were combined to obtain the NMR spectra. Even so, the total mass of sample on which the 80-kbar spectrum was obtained was only 23 mg, a marginal quantity. To obtain the spectrum displayed in Fig. 2 for this sample, we had to collect and average 700,000 individual scans, requiring a total instrument time of 13 h.

NMR spectra were obtained on a Bruker CXP 300 spectrometer using the samples as synthesized (usually fragmented) without further treatment. Glass samples were suspended in powdered KBr in the Andrew type spinner. The KBr was useful for checking the spinning angle[13,14]. Samples can easily be separated from the KBr when desired by dissolving the KBr in water.

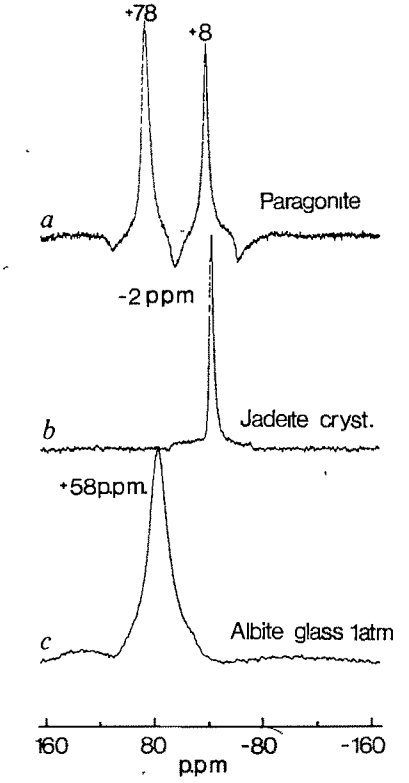

Fig. 1 ^{27}Al-NMR spectra in *a*, crystalline paragonite $(NaAl_2(Si_3AlO_{10})(OH)_2$, *b*, jadeite $(NaAlSi_2O_6)$; and *c*, albite $(NaAlSi_3O_8)$, showing positions of the resonance for Al^{3+} in tetrahedral and octahedral sites referenced to $Al(H_2O)_6^{3+}$ in aqueous solution.

The ^{27}Al spectra were recorded at 78.2 MHz in a field of 7 T in the Fourier transform mode. The sweep width was set to 30,000 Hz and memory size to 8 K. The usual $\pi/6$ pulses of 4 μs were applied and 10,000 free induction decays (FIDs) were collected with a repetition rate of 100 ms. A dead time of 200 μs was chosen to avoid any contribution from Al metal from the probe. The rotation rate was chosen to be 2,500 Hz (32 p.p.m.) to keep rotation bands outside the range of interest, but still inside the spectrum (as is well exemplified by the paragonite spectrum (see Fig. 1*a*)). Aluminium chemical shifts were measured relative to a solution of 1 M $Al(NO_3)_3$ in 1 M HNO_3.

^{27}Al chemical shifts are known to be very sensitive to the Al coordination state[14] and hence make an excellent probe for structural changes. Mostly, the ^{27}Al resonances in different coordination states fall into two distinct regions with almost no overlap. We illustrate this in Fig. 1 using aluminosilicates of known structure that are related to the structure of albite.

In paragonite, $NaAl_2(Si_3AlO_{10})(OH)_2$ (a Na-mica), 33% of the Al^{3+} occurs in tetrahedral sites, 66% in octahedral sites. The latter appear to contribute less intensely to the spectrum (because of broadening by the second order quadrupole interaction) and no quantitative information can be extracted presently from peak areas or intensities. The tetrahedral Al^{3+} resonance occurs at 78 p.p.m. and the octahedral peak at +8 p.p.m. relative to $Al(H_2O)_6^{3+}$. In crystalline jadeite $(NaAlSi_2O_6)$ (which was here prepared by melt crystallization at 60 kbar), all Al^{3+} ions are in octahedral sites, and the resonance occurs at −2 p.p.m. (Fig. 1*b*).

As Müller *et al.* have pointed out[15], the ^{27}Al chemical shifts are sensitive to the second nearest-neighbour coordination shell, the tetrahedral spectrum being the more sensitive to this effect. Thus, albite glass, with tetrahedrally coordinated Al^{3+} (Fig. 1*c*), has its resonance at 58 p.p.m., 20 p.p.m. downfield from the equivalent paragonite band. For jadeite, where Al^{2+} is octahedrally coordinated, the shift from the equivalent paragonite band is only 10 p.p.m. In each type of site in paragonite, Al^{3+} evidently experiences a higher electron density than in jadeite or albite,

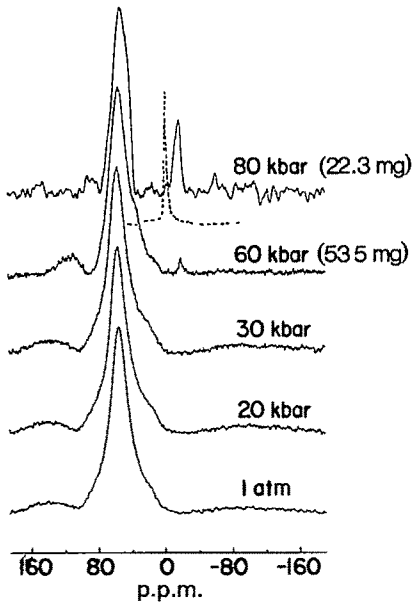

Fig. 2 ^{27}Al-NMR spectra of glassy albite samples cooled from the melt at normal pressures (lower spectrum) and at 20, 30, 60 and 80 kbar, as marked. All spectra have been normalized to the same tetrahedral peak intensity. The spectrum of ^{27}Al in jadeite (scaled to half size) is included as a dashed curve for comparisons of chemical shift with the glass octahedral component. The latter is broader than the unscaled jadeite spectrum by ~50% at half height, but somewhat narrower than octahedral Al in ambient pressure phosphate glasses[13].

which is presumably caused by a greater separation of the Al^{3+} from the between-sheet charge-compensating alkali cation in the mica. The best illustration of the spectral sensitivity to such second-neighbour effects may be seen from the study of natural feldspars containing a variety of charge-compensating cations that give rise to multiple tetrahedral site resonances, one for each type of cation, separated by ~5 p.p.m. (our unpublished results). Site distortions due to variations in local topology in a glass may be expected to produce a similar though continuous spread of resonance frequencies.

The spectra for the normal and high-pressure albite glasses are collected in Fig. 2. Because of its importance in interpreting the 80-kbar glass sample spectrum, the jadeite spectrum is also included in Fig. 2 (light-dashed peak). It is clear that no changes in the coordination or even the site symmetry of Al^{3+} in albite glass occur under pressure increases of up to 30 kbar at least. Indeed, the spectra, once normalized to the same peak intensity, can be superimposed almost within the noise level. The persistence of this spectrum over such a pressure range implies that octahedrally coordinated Al^{3+} ions are probably not to be found in any ambient pressure oxide glasses[4] unless the oxide ions being coordinated are pre-polarized by powerful species such as P(V)[13] S(VI) or Re(VII). Our results are also consistent with the absence of evidence for octahedral Al^{3+} in an earlier Raman spectral study of jadeite glass vitrified under pressures up to 40 kbar.[3] In the absence of coordination changes, the compression of liquid albite must be accomplished by decreases in the Al–O–Si and Si–O–Si bond angles. The compression involves rotation of the tetrahedral packing units to permit closer oxygen packing, as described earlier for the liquid state compaction of SiO_2 itself[16]. This will occur more easily for adjacent AlO_4 tetrahedra and SiO_4/AlO_4 pairs than for SiO_4/SiO_4 pairs because of the smaller cation–cation repulsion involved. It seems consistent with such effects that the diffusion coefficients of trivalent cations should rise more rapidly with compression than those of tetravalent cations, as shown by Kushiro's elegant interdiffusion experiments on jadeite-type couples[17].

Unfortunately, we do not have samples in the range 30–60 kbar. It seems that somewhere in this range the tetrahedral AlO_4 units have begun to suffer some distortion (note the shoulder on the 60-kbar spectrum), but the factors governing the line shape in ^{27}Al-NMR are sufficiently complex that we are presently unable to specify the nature of the distortion. ('Fingerprinting' with crystalline samples of known tetrahedral distortions and also with 5-coordinated Al^{3+} will be described elsewhere.) Together with the increased distortion is the simultaneous appearance of a small peak of −16 p.p.m., which rises above the noise level in the 60-kbar spectrum. In the 80-kbar sample spectrum, this new band has risen to almost half the height of the residual tetrahedral spectrum. Comparison with the paragonite spectrum suggests that a considerable fraction of the Al^{3+} is now in octahedral coordination. In the 80-kbar spectrum the tetrahedral spectrum is narrower and indeed its full width at half height is somewhat smaller than in the glass prepared in ambient conditions.

The new band at −16 p.p.m. is evidently not attributable to residual unseparated jadeite, the spectrum of which peaks at −2 p.p.m. (see Fig. 2). Only jadeite and co-crystallized coesite were detected in the X-ray examinations (and removed, see above), so the new band seems unlikely to be attributable to crystalline material, despite its narrowness. The possibility that it is a metastable jadeite precursor phase distributed in crystallites too small (<100 Å) to give detectable X-ray lines, although unlikely, cannot be eliminated without performing annealing studies on the high-pressure glass. These will be performed once the glass has been fully characterized. Al_2O_3, an alternative possible phase in high-pressure crystallization conditions, has a resonance in the range +4–0 p.p.m. according to our examination of samples from eight different sources, and hence cannot explain our results.

The simplest interpretation of our observations is that the initial effect of very high pressure ($P > 40$ kbar) on the framework liquid is a distortion of the tetrahedral symmetry around Al^{3+} (note the shoulder, Fig. 2), which is then relieved at higher pressure ($P > 60$ kbar) by the splitting off of a tightly defined subgroup of octahedrally coordinated Al^{3+} ions, the concentration of which will depend on the applied pressure.

These observations are not inconsistent with the results of ion dynamics computer simulation studies on liquid jadeite[5,6], which showed that both Al and Si coordination numbers could be changed with application of sufficient pressure to the high-temperature liquid. The change occurred at lower pressures for Al^{3+}, ('midpoint' at about 100 kbar) than for Si (midpoint at ~200 kbar). However, because of the high temperature that had to be maintained in these computations (for structural equilibrium to be reached within acceptable computation times), distinct coordination states were not discernible; the midpoint corresponded to an average coordination of five.

The observations are also qualitatively consistent with predictions based on the assumption of structural similarities between melt and the crystalline phase with which it is in equilibrium (quasi-crystalline melt model). For instance, jadeite only occurs at the albite liquidus above 32 kbar pressure at ~1,430 °C[18], so both 20- and 30-kbar samples, in which Al is exclusively in 4-coordination (Fig. 2), would have albite on the liquidus. The $6 \rightarrow 4$ equilibrium is presumably dependent on temperature, and it should be remembered that the equilibrium being frozen is that which exists at the glass transition temperature, T_g, which usually is at 0.6–0.7 T_m. Because the albite/jadeite boundary on the T/P phase diagram has a positive slope, the quasi-crystalline model evidently overestimates the tendency towards octahedral coordination of Al in the melt. It suggests, however, that the 6-coordinated state of Al is more easily generated at the jadeite composition although a poorer resistance to crystallization, probable at this composition, could hamper its observation by the present 'preserve-and-look' approach.

E.O. thanks A. E. Ringwood for encouragement during this work and W. Hibberson and A. Major for technical assistance with the experiments. C.A.A. thanks the NSF for Solid State Chemistry grant DMR-8007053 for support of this work, the CNRS (France) for partial support during a visit to ESPCI, and

P. Papon, J. Leblond, T. Teixeira and colleagues for their hospitality. We thank R. Couty from the Laboratoire de Géologie of l'Ecole Normale Supérieure for providing some synthesized paragonite, and natural and synthetic Al_2O_3 samples.

ESR dating of volcanic ash

Noboru Imai & Koichi Shimokawa

Geological Survey of Japan, 1-1-3 Higashi, Yatabe, Tsukuba, Ibaraki, Japan

Michio Hirota

Meteorological Research Institute, 1-1 Nagamine, Yatabe, Tsukuba, Ibaraki, Japan

Radiation-induced centres of Al, Ti, Ge and E′ occurring in the natural quartz of various geological materials were discussed a decade ago by McMorris[1,2]; but it is only recently that the peroxy centre for natural flint[3], the E′ centre for quartz from a fault[4] and the Ge centre for quartz from welded tuff[5] have been used for electron spin resonance (ESR) dating. The ages of volcanic ash or lava have been obtained by thermoluminescence (TL) dating using fine (2–11-μm) volcanic glass[6] or plagioclase feldspar[7], respectively. However, ESR dating of volcanic ash has proved extremely difficult because signal intensities of radiation-induced centres measured at room temperature are weak compared with the interfering signals from paramagnetic impurities such as Fe^{3+} and Mn^{2+}. Here we have used a signal from a quartz aluminium centre, measured at 77 K, where it is several orders of magnitude greater than those of the E′ or Ge centres at room temperature. The aluminium-centre ESR signal can also be observed in plagioclase feldspar and volcanic glass, allowing the age of the volcanic debris to be determined using any of the three mineral compounds.

The method was tested in three samples whose ages had already been obtained by other methods. Quartz was extracted from Tamagawa rhyolite welded tuff (TM1) in Hachimantai (north-east of Japan), plagioclase from Aira-Tn ash (TTS34) of Kokubu in Kagoshima Prefecture (south of Japan) and volcanic glass from volcanic ash (TE5) in the Ohiso hills (middle of Japan) or from the upper portion of the Takio Formation in the Ohita Group (south of Japan). Quartz grains, 2–3 mm in diameter, from the Tamaga welded tuff were hand picked after crushing the rock and then cleaned by 3 M HCl. The grain was crushed gently and sieved to obtain 0.25–0.125-mm particles. Volcanic glass and plagioclase feldspar were isolated by heavy liquid separation (with specific gravities of 2.5 and 2.8) after the sample has been washed in water, sieved to 0.25–0.125 mm and cleaned both ultrasonically and with 3 M HCl. Each sample was examined microscopically and found to be of greater than 90% purity. For the ESR measurement, 200-mg samples of volcanic glass and 100-mg samples of quartz and plagioclase were used. An X-band spectrometer (JEOL FE) was used at 77 K with 100-kHz field modulation. Artificial γ-irradiation was carried out with a ^{60}Co source. Measurements were repeated five times with the same sample so that average values could be obtained. The concentration of uranium and thorium was determined by spectrophotometry using arsenazo III and torin, respectively, after solvent extraction of tri-*n*-octylphosphine oxide (TOPO)/cyclohexane[8,9]. The potassium content was determined by atomic absorption spectrometry[10].

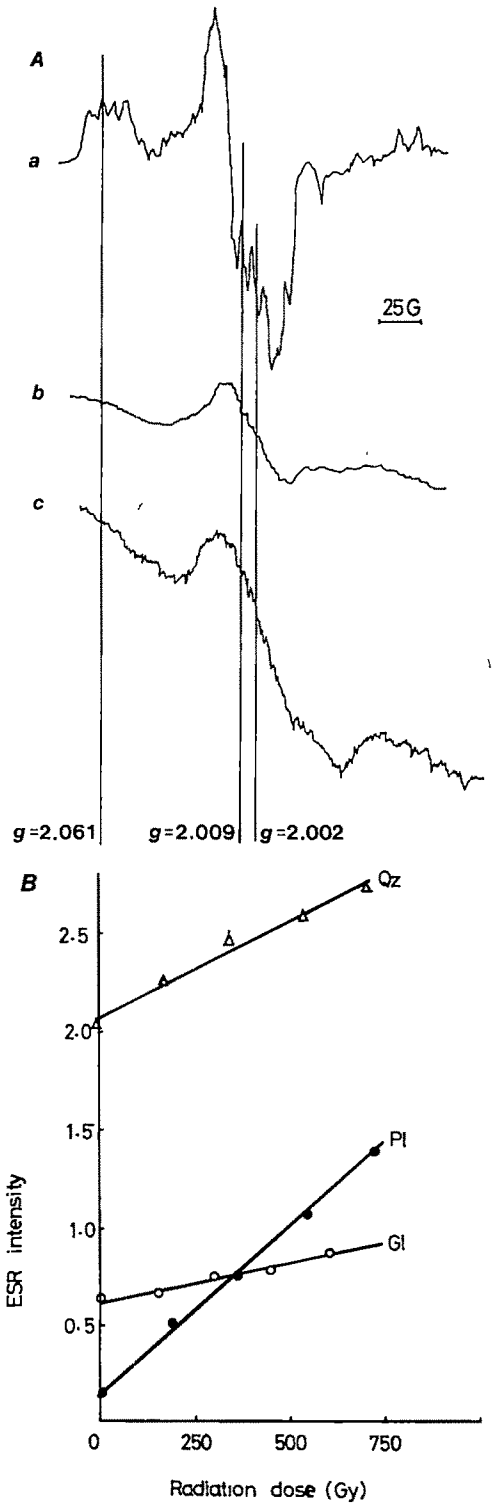

Fig. 1 *A*, The ESR spectra of Al centre in natural quartz TM1 (*a*), plagioclase TTS34 (*b*) and volcanic glass TE5 (*c*). The principal values of the *g* tensor of this centre[11] are shown. *B*, The relation of signal intensity with radiation dose for quartz (△), plagioclase (●) and volcanic glass (○).

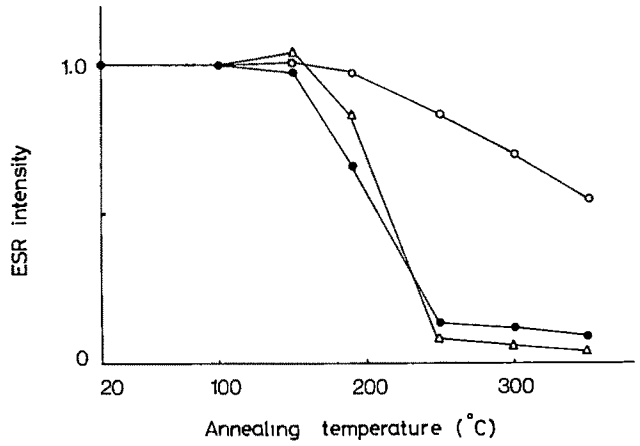

Fig. 2 Thermal annealing of Al centre in quartz TM1 (△), plagioclase TTS34 (●) and volcanic glass TE5 (○). Annealing temperature was maintained for 15 min in each step.

Figure 1*A* shows the ESR spectra of the aluminium centre in natural quartz, plagioclase and volcanic glass. An aluminium centre is a defect in which an aluminium ion replaces the silicon site and a hole is trapped at one of the four ligand oxygens. Schnadt and Räuber reported the ESR spectrum of this defect in quartz powder and fused glass[11]. The signal is measured at 77 K and broadens beyond the detection at room temperature in quartz powder. The signal intensity in plagioclase and volcanic glass is several times smaller because of extra line broadening due to a more distorted crystal field or to a looser lattice structure.

We have investigated the thermal annealing of the Al centre. Isothermal experiments were performed at several temperatures for quartz (TM1), plagioclase (TTS34) and volcanic glass (TE5) and the mean lifetimes of the traps were estimated to be 1.8–3.8 Myr, ~4 Myr and 10^3 Myr, respectively, at 10 °C. The frequency factor was assumed to be $3\times10^{12}\ s^{-1}$ and trap depth was 2.4 eV for quartz and plagioclase and 2.8 eV for volcanic glass. The changes of the ESR signal for quartz, plagioclase and volcanic glass on successive heating (for 15 min) are shown in Fig. 2. The quartz and plagioclase signals almost disappeared above 250 °C, whereas that of volcanic glass changed only slightly at that temperature, indicating that the aluminium centre in volcanic glass is much more stable. Moreover, above 250 °C, in plagioclase and volcanic glass, a large peroxy-centre signal appeared in the middle of the aluminium centre signal.

Figure 1*A* shows the ESR spectra of the aluminium centre the irradiation dose. The total dose was obtained by extrapolating the least-square-fitting line. The radiation for the minerals is assumed to be the sum of the internal α radiation and the external β and γ radiations considering the grain size of 0.25–0.125 mm. The annual dose was calculated from the analyses of the internal and bulk contents of uranium, thorium and potassium using Bell's data[12]. The α-efficiency, or k factor, is tentatively assumed to be 0 for quartz[4], 0.20 for plagioclase[7] and 0.04 for volcanic glass[13]. The internal and bulk uranium, thorium and potassium concentrations, annual dose and ESR age are shown in Table 1. For our calculation the internal α dose for TTS34 plagioclase was taken as only 6%, because the internal contents of uranium and thorium are very small, whereas that for TE5 volcanic glass is 11%. In addition to this, the external α dose (the size effect) gives an error of 7% for plagioclase and 0.6–1.4% for volcanic glass assuming a 10% external α-dose contribution[13]. However, these were not included in the calculation.

The ESR age of quartz samples (TM1) was 1.13 Myr, which agrees with the fission track age of 1.2 Myr (ref. 14). The ESR age of plagioclase of TTS34 was 2.8×10^4 yr. The ^{14}C age of widespread tephra of Aira-Tn (AT) ash has been determined to be $2.1–2.2\times10^4$ yr (ref. 15). (Note, however, that ages of $2–10\times10^4$ yr were obtained for volcanic glass samples of the AT ash from several different locations.) The ESR age of the volcanic glass of TE 5 is 0.34 Myr which agrees well with the fission track age of 0.39 Myr obtained using zircon[16]. This agreement encouraged us to apply the method to a suite of volcanic ashes of unknown ages.

The ESR ages of six volcanic ash layers in the Takio Formation of the Ohita Group were obtained using volcanic glass, as shown in Table 2. The concentration of uranium, thorium and potassium varies in each bed and, hence, the annual dose varies from 1.69 to 3.89 Gy yr^{-1}. However, the ESR age increases from 0.49 to 0.82 Myr in agreement with the stratigraphical sequence. The volcanic ash in this area has been correlated with the upper part of the Ohsaka Group (0.3–0.8 Myr)[17].

Another possible use of ESR is for 'fingerprinting' the ash layers. The ESR spectra of the aluminium centre in the AT ash from different locations have the peroxy-centre signal in the middle of aluminium-centre signal. In our work, two out of three samples of plagioclase and five out of eight samples of volcanic glass have peroxy-centre signals. In other volcanic ash, none of the 15 samples of plagioclase and only two out of 28 samples of volcanic glass exhibit this signal, which may thus be unique to AT ash. In the annealing experiment, the peroxy centre appears above 250 °C for plagioclase and volcanic glass, which suggests the mechanism by which this signal is formed.

Table 1 Radioactivity data, total dose and ESR ages for samples of known age

Mineral	U (bulk p.p.m.)	U (internal p.p.m.)	Th (bulk p.p.m.)	Th (internal p.p.m.)	K (%)	Annual dose (Gy yr^{-1})	Total dose (Gy)	ESR age (Myr)	Age from other work (Myr)

Oxygen isotope fractionation between amorphous silica and water at 34–93 °C

Itsuro Kita*, Sachihiro Taguchi† & Osamu Matsubaya*

The fractionation factor of oxygen isotopes between quartz and water has been extensively studied from experimental[1,2], theoretical[3,4,5] and empirical viewpoints[6] and has been widely used to estimate the isotopic composition or the temperatures of water relating to various geological processes. At lower temperatures, where hydrothermal processes, diagenesis and other processes take place, however, the fractionation factor for quartz as well as other silica minerals has not been studied thoroughly. We report here experimentally determined oxygen isotope fractionation factors between amorphous silica and water at 34–93 °C, obtained by measuring the oxygen isotope ratios of amorphous silica precipitated from geothermal waters of power plants. The relationship between the fractionation factor and temperature is similar to the extrapolated relationship of quartz observed at higher temperatures. This result is useful for the oxygen isotope study of water–rock interactions at temperatures below 200 °C.

The amorphous silica was precipitated at four points (P-1, P-2, P-3 and P-4) along the reinjection lines in the Otake and Hatchobaru geothermal power plants. Although it would have been preferable to obtain the amorphous silica at many points over a wide range of temperatures, these four points were the only ones available for this experiment. The same geothermal water from the Otake station flows at P-1 and P-4; at P-2, the geothermal waters from both stations are mixed; at P-3, the geothermal water is from the Hatchobaru station. The temperatures of flowing geothermal waters are 93, 87 and 81 °C at P-1, P-2 and P-3, respectively. The temperature at P-4 gradually decreased from 70 °C to atmospheric temperature during this study because of silica scaling in the pipeline. Samples of amorphous silica were collected at 58 and at 34 °C.

The differences in the chemical character and roughness of surface of the materials on which amorphous silicas were precipitated may influence the oxygen isotope fractionation factor between amorphous silica and water. Materials such as wire, stainless steel tubing, glass tubing, rock, wooden rod and Teflon plate were immersed in the geothermal waters at P-1 and P-4. At P-2 and P-3, only wire was used. The materials were immersed in the geothermal waters for about two weeks at P-1 and P-3, and one month at P-2 and P-4. During these periods, the geothermal waters were collected at least once in a day and their temperatures, oxygen isotope ratios, and Cl^- and total silica contents were measured. At P-2, however, these measurements were done at intervals of a week. The temperatures and oxygen isotope ratios of geothermal waters fluctuated within the errors shown in Table 1.

The *p*H, and Cl^- and total silica contents are 8.3, 1,680 p.p.m. and 525 p.p.m., respectively, at P-1, and 6.9, 2,870 p.p.m. and 730 p.p.m., respectively, at P-3. The fraction of ionic silica in the total silica was also determined. The ionic silica is determined using a conventional molybdate yellow method for an aliquot of geothermal water of which the *p*H was adjusted to ~1.2–1.5 just after collection. Most of the total silica is ionic at P-1, whereas about 90 and 55% is ionic at P-2 and P-3, respectively. This is mainly because of the differences in *p*H and the time elapsing after the geothermal water was separated from the steam[7,8]. The content of ionic silica was not measured at P-4.

The precipitated silica did not contain any crystalline materials which could be detected by X-ray diffraction, except for the samples at P-1 which contain kaolinite of < 5 wt%. From the results of chemical analysis of silica scales at the geothermal plants[9], the precipitated silica seems to have impurities of less than a few per cent. Such a small amount of contamination does not significantly affect the oxygen isotope ratio of amorphous silica.

The oxygen isotope ratios of amorphous silica and geothermal water were measured using a fluorination[10] and an H_2O–CO_2 equilibration method, respectively. The isotope ratios were expressed as $\delta^{18}O$ values relative to the SMOW standard. The $\delta^{18}O$ of silica was referred to SMOW on the basis of a fractionation factor of 1.0407 between CO_2 and H_2O (ref. 11). The $\delta^{18}O$ value of NBS-28 is +9.36‰ in this method.

Table 1 $\delta^{18}O$ values of amorphous silicas precipitated from geothermal waters on various materials and for the geothermal waters, and the fractionation factor between amorphous silica and water

Sampling point	Temperature (°C)	Date	Materials	$\delta^{18}O_{SMOW}$ (‰) Amorphous silica	$\delta^{18}O_{SMOW}$ (‰) Geothermal water	Fractionation factor (α)
P-1	92.7 ± 0.3	August 1983	Iron wire	15.2	−5 4 ± 0.1	1 0207
			Wooden rod	15.6		1.0211

P-4	34 ± 5	February 1983	Iron wire	27.5	−5.4 ± 0 1	1.0331

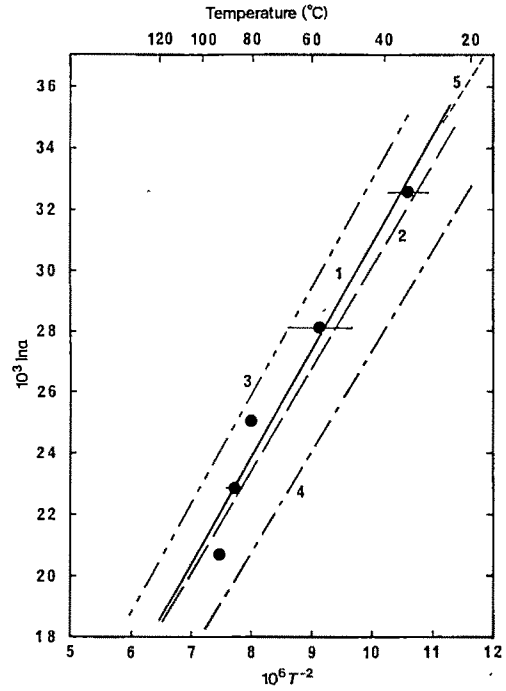

Fig. 1 Comparison of the oxygen isotope fractionation factor between amorphous silica and water with those previously reported for quartz. ●, Present results. Line 1, the least square fitting in the present study. Line 2, from refs 1, 2. Line 3, from Taylor (cited in ref. 3) Line 4, from ref 4 Line 5, from ref. 12

The dehydration of hydrous silica changes the oxygen isotope ratio of the silica remaining[6] In this study, however, air-dried amorphous silicas were preheated in vacuum at 200 °C for 3 h before the reaction with fluorine gas, for the following reasons.

The SiO_2 content calculated from the amount of oxygen extracted by fluorination ranged from 88 to 95 wt%. These reductions (5 to 12 wt%) in content correspond to the weight loss when the amorphous silicas were heated at 1,000 °C. Therefore, these reductions must be due to dehydration of silica during preheating. In that case, the water in the amorphous silica can be completely removed at 200 °C, and much of the water should be removed at temperatures below 200 °C. The water removed at such lower temperatures may be simply adsorbed water, or water weakly combined with silica, the dehydration causes very little change in the oxygen isotope ratio of silica remaining[12].

As shown in Table 1, the amorphous silicas precipitated on the different materials both at P-1 and at P-4 have the same $\delta^{18}O$ value at each point. This indicates that the difference in the character of surface of the materials does not influence the oxygen isotope fractionation between silica and water. Scanning electron microscopy confirms that the difference in the character of surface has no effect on the morphology of amorphous silica.

The fractionation factors (α) between amorphous silica and geothermal water are given by

$$\alpha = (1+10^{-3}\delta^{18}O_{silica})/(1+10^{-3}\delta^{18}O_{water})$$

as shown in Table 1. The relationship of $\ln\alpha$ to reciprocal temperature square is almost linear, as seen in Fig. 1, and is approximated by

$$10^3 \ln\alpha = 3.52(10^6 T^{-2}) - 4.35$$

This relationship is similar to that of the equilibrium fractionation factor between quartz and water. It is especially close to the extrapolated relationship between quartz and water as determined experimentally by Clayton *et al.*[1] and Matsuhisa *et al*[2]

Knauth and Epstein[6] estimated the fractionation factor between quartz and water to be 1.039 at 0 °C using the observed oxygen isotope ratio of a microcrystalline quartz in an oceanic sediment. This value is close to the relationship determined by Kawabe[4] and lower by about 5‰ than the present result. Labeyrie's[12] measurement of the fractionation between silica in sponges and diatoms and water is very close to the present one.

An interesting problem is whether the oxygen isotope fractionation takes place among polymorphs of silica. In the case of α and β quartz, for instance, fractionation of 0.8 to 1.5‰ is theoretically predicted[3,4], although no evidence has been found from experimental studies[2]. In the case of amorphous silica, the problem is whether a definite fractionation factor is available, because amorphous silica has no definite crystal structure. Nevertheless, the present result suggests that the extent of fractionation between amorphous silica and quartz may be smaller than the extent of variation in the equilibrium fractionation factors reported in the literature for the quartz-water system.

We thank Kyushu Electric Power Co. for the use of reinjection lines in Otake and Hatchobaru Geothermal Plants; also Professor A. Koga for valuable advice on the chemical analyses of geothermal waters, and H. Etchu for help in isotopical analyses of geothermal waters. This work was supported financially in parts by Grant-in-Aid for Encouragement of Young Scientist (no. 58740392) and for Energy Research (no. 56045021) from the Ministry of Education, Science and Culture, Japan and by Cooperative Program provided by Geothermal Research Center of Kyushu University.

Major Asian aeolian inputs indicated by the mineralogy of aerosols and sediments in the western North Pacific

Marsha Blank*, Margaret Leinen† & Joseph M. Prospero*

* Rosenstiel School of Marine and Atmospheric Science, 4600 Rickenbacker Causeway, Miami, Florida 33149-1098, USA
† Graduate School of Oceanography, University of Rhode Island, Kingston, Rhode Island 02881, USA

Recent atmospheric chemistry studies have shown that substantial quantities of soil material are being transported out of Asia and across large regions of the North Pacific[1,2]. In the central North Pacific, the estimated[1] ($6-12\times10^{12}$ g yr^{-1}) and measured[2] (20×10^{12} g yr^{-1}) deposition rate of mineral aerosols could account for a substantial fraction of the non-biogenic portion of deep-sea sediments in this region, where sedimentologists have previously estimated that 75–95%[3,4] of the surface sediment is derived from atmospheric dust fallout. The quantitative importance of wind-transported (aeolian) material to sedimentation in the North Pacific would be more firmly established if it could be shown that the composition of the present-day soil aerosol is similar to that of mineral particles in the underlying sediments, which have been deposited over a period of thousands of years. Here we compare the compositions of soil aerosols and sediments collected from the western North Pacific and find that their mineralogies are identical, except for one mineral. This supports the hypothesis that the sediments are heavily impacted by aeolian sources.

The mineralogy of the <2-μm size fraction of both aerosols and sediments was determined by X-ray powder diffractometry using methods developed specifically for <2-μm sediments[5]. This size fraction should yield a substantial fraction of the total aerosol mass, which has a median diameter of ~2 μm[6,7]. Aerosols of this size have a very small settling velocity in the atmosphere; hence, they will have a relatively long residence time and their composition will be little affected by changes due to differential settling of different-sized mineral constituents.

The sediment samples were taken from the tops of 12 piston cores (Table 1*b*) collected during R/V *Vema* cruise 36-12 (Fig. 1). Core sites are located on the seaward side of the western Pacific trenches in an area where there is no evidence of turbidites[8] or of inputs from ice rafting[9]. On the basis of their locations, mineralogy and stratigraphy, it has been suggested that the inorganic (non-biogenic)-mineral component of the sediments is predominantly aeolian in origin[10,11]. Although there are differences in sedimentation rates between the areas sampled by coring, there is no evidence of extensive reworking of sediments by bottom currents or erosion at the sites[12]. Finally, the average age of the sediments used for this study is <10 kyr[13]. Thus, they probably have not been influenced by the major climatic changes associated with Pleistocene glaciations, with the possible exceptions of the three cores 33P, 45P and 49P, which show ages of 12–17 kyr[13].

The mineral aerosols were collected with two 1-m^2 nylon mesh samplers[14] aboard the DV *Glomar Challenger* during the Deep-Sea Drilling Project (Table 1*a*) in the western North Pacific (Fig. 1). Of the samples collected in this region, the six largest were selected for analysis. Previously, there has been concern that the collection efficiency of the meshes may vary with particle size so that the samples would not be representative of the total aerosol[14–16]. In a recent study, however, the <2-μm mineralogies of soil aerosols collected concurrently with filters and with meshes were found to be identical except for smectite, which was underestimated in the mesh samples relative to the filter samples by a factor of about two (M.B. and J.M.P., in preparation).

Sediment samples were treated with sodium acetate (buffered to *p*H 4.8 with acetic acid) to remove $CaCO_3$, with 0.4 M Na_2CO_3 to remove biogenic silica (opal), and with a Na dithionite/Na citrate solution to remove amorphous iron and manganese oxides[17]. Subsequent treatment and analysis was identical for both aerosol and sediment samples. Bulk aerosol sample masses ranged from 0.4 to 4.3 g per sample. Part (200–500 mg) of each sample was saturated with 1.0 M $MgCl_2$ (ref. 5). Size separations were made by wet-sieving at 20 μm diameter. The <2-μm fraction was isolated by a settling procedure. To increase the precision of X-ray analysis, an internal standard of 10 wt% <2-μm talc was added to each <2-μm sample[5], which was then deposited as a slurry on a 0.45-μm silver filter and X-irradiated[5] (see Table 3). The peak areas for illite, smectite, kaolinite, chlorite, quartz and plagioclase were converted to wt% using the weighting factors determined by Heath and Pisias[5] for modern North Pacific sediments. Amphibole concentrations were undetectable or present in only trace amounts. The sum of the wt% of the major mineral components is equivalent to the percentage of diffracting phases in the sample. The average

Samples were X-irradiated on a Phillips Norelco X-ray diffractometer using Ni-filtered CuKα radiation at 40 kV and 25–40 mA. Samples were scanned over the range 3–30° (2θ) at a rate of 1 deg min^{-1}. Weight percentages are normalized to maximum percentage diffracting, 80.4%

percentage of diffracting phase in the aerosols was 55.7% and that for the sediments was somewhat higher, 71%, because more amorphous component was removed before X irradiation. The residual fraction (100 − % diffracting) is composed of poorly crystalline minerals and X-ray amorphous phases in the sample[5]. To facilitate the comparison of the different samples, the mineral percentages were normalized to the maximum diffracting percentage, 80.4%.

The variability in X-ray clay mineral analysis can be very high because the analyses are extremely sensitive to sample preparation and instrumental effects. Multiple runs were performed of many samples to assess the analytical precision and, in one case, an aerosol sample was subsampled and analysed eight different times to determine the error due to sample preparation and day to day variability in the X-ray diffractometer. The precision is good with the exception of smectite (Table 2).

The mineralogies of the mesh samples and the sediments are strikingly similar (Table 3). The differences in composition between the two materials are less than the analytical variability except for smectite. Statistical f-tests and Student's t-tests indicate that the aerosols and sediments are statistically identical (99% confidence level) except for smectite. This difference for smectite is probably not significant, because of the relatively low precision in smectite analysis, the small percentages involved and the possible undersampling of smectite by the mesh samplers. The amount of biogenic opal and other non-terrigenous components in the bulk sediment ranges from 2–20% in the area of our cores[10], which, with the above evidence, suggests that the remaining 80–98% of the sediment is aeolian in origin and that aeolian inputs dominate the deep-sea sedimentation there. The location of our samples, atmospheric haze data[18] and the results of North Pacific dust trajectory studies (J. T. Merrill *et al.*, in preparation) suggest that the arid regions of Asia are the source of the mineral aerosol.

The rate of mineral aerosol deposition in this region seems quite high. The total dust deposition rates measured recently at island stations 3,500–5,600 km east of the Vema core locations are 0·064 g cm^{-2} kyr^{-1} at Midway and 0.043 g cm^{-2} kyr^{-1} at Oahu[1]. Average sedimentation rates for the cores vary from 0.86 cm kyr^{-1} for the cores near 152° E to 0.67 cm kyr^{-1} for those near 164° E[13] and dry sediment bulk densities average 0.3–0.4 g cm^{-3} for both areas[19]. If ~80% of this material is aeolian, the average mass accumulation rates of aeolian material for the two core areas are 0.24 g cm^{-2} kyr^{-1} and 0.18 g cm^{-2} kyr^{-1}. These higher rates may be attributable to the fact that the Vema sites are closer to the Asian sources where dust fluxes could be substantially higher. We have estimated a mean dust concentration for the core locations using that measured in the Sea/Air Exchange (SEAREX) programme's North Pacific island network[2,6] and Asian dust concentrations measured in a similar network in Japan (M. Uematsu, personal communication). A semilogarithmic interpolation between these networks yields a mean mineral aerosol concentration of 6–10 μg m^{-3}. On the basis of deposition models developed in the SEAREX studies[1], we estimate the mineral aerosol deposition rate at the core sites to be 0.2–0.3 g cm^{-2} kyr^{-1}, in good agreement with the measured aeolian sediment accumulation rates. These results suggest that the present rate of dust transport out of Asia is representative of transport over the past few thousand years. It follows that the non-biogenic mineral components in North Pacific sediments could be a good indicator of palaeoclimatic conditions such as aridity, wind velocity and large-scale atmospheric circulation patterns.

This work was supported by NSF grants OCE-8008354, DES 74-0835 (J.M.P.), OCE 8-24368 and ATM 80-18896, and by SANDIA contract 73-7888 (M.L.). We thank G. R. Heath for samples of the Vema 36-12 cores and D. Savoie, G. Podesta and M. Cummings for their assistance.

Thermogenic hydrocarbons in surface sediments of the Bransfield Strait, Antarctic Peninsula

M. J. Whiticar*, E. Suess† & H. Wehner*

* Bundesanstalt für Geowissenschaften und Rohstoffe, Stilleweg 2, 3000 Hannover, FRG
† College of Oceanography, Oregon State University, Corvallis, Oregon 97331, USA

Antarctica is the only continent from which petroleum deposits have not been encountered, despite the occurrence of potential hydrocarbon basins onshore and around its margins. We have discovered thermogenic hydrocarbons in unconsolidated Recent sediments from the King George Basin, Bransfield Strait, west Antarctica. These sediments possessed a marked petroliferous smell throughout the length of the 8.6-m gravity core. The basin sediments are glacial marine deposits dominated by turbidites and contain abundant autochthonous organic matter as a result of high seasonal primary productivity in this most fertile part of the circumpolar ocean[1]. The maturation of this material into hydrocarbons may have been accelerated by the high geothermal gradient in the basin, associated with back-arc spreading created by the subduction of the Drake Plate into the South Shetland trench[2]. Sediments in this rifted basin are frequently intruded by volcanic sills and dykes[3] giving rise to acoustic features shown in Fig. 1. The presence of these thermogenic hydrocarbons provides the first demonstration of active source rocks in Antarctica.

On core retrieval, the liners were immediately cut into 1-m sections and ~500 g of wet sediment removed to a freezer and kept at −80 °C until analysed (within 24 h). The analytical procedure for the molecular and stable isotope composition of the hydrocarbon gases is similar to that given elsewhere[4]. The bitumen fraction (C_{15+}) was extracted with CH_2Cl_2 by soxhlet, partitioned by liquid chromatography (LC) and analysed by gas chromatography/mass spectrometry[5]. Interstitial waters were pressure filtered immediately after coring. Total dissolved carbonate (ΣCO_2) was determined by gas chromatography following acidification and stripping of the sample and dissolved sulphate (SO_4^{2-}) was determined gravimetrically.

Methane yields are low in the uppermost 3 m (< 32 parts per 10^9 wt gas/wt sediment) then increase to a maximum of 153 parts per 10^9 at 450 cm (Fig. 2). The distribution of ethane to pentane hydrocarbons (C_{2+}) roughly covaries with methane, with a maximum of 197 parts per 10^9 in the sediments (Table 1*a*). In addition, some of the gas chromatograms from the deeper samples reveal C_6 and C_7 hydrocarbons in concentrations even greater than those of C_1–C_5. Unsaturated hydrocarbons, ethene and propene were present in only minor amounts in comparison to the *n*-alkanes. Within the C_{2+} fraction, the concentration tends to increase corresponding to carbon number below 650 cm (Table 1*b*). Relative to methane the C_{2+} gas fraction is greater at depth, with % wetness ratios ($[\Sigma C_{2-5}/\Sigma C_{1-5}] \times 100$) reaching values of 39%. The high % wetness here is related to hydrocarbon formation via thermal processes, rather than via diagenetic processes which may produce minor quantities of C_{2+} (ref. 6).

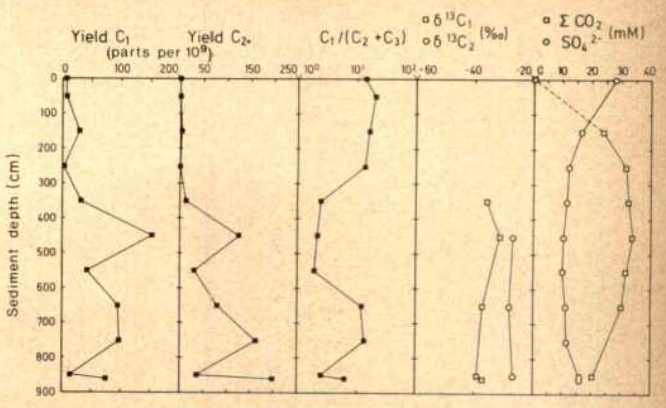

Fig. 2 Hydrocarbon gas concentrations of methane (C_1) and ethane through pentane (C_{2+}) increases with sediment depth in core 1140. Thermogenic gas signature confirmed by $C_1/(C_2+C_3)$ and by $\delta^{13}C_1$ and $\delta^{13}C_2$ values in the thermal range. The presence of sulphate throughout the core precludes *in situ* biogenic methane production. Remineralization of organic matter appears to cease below 300 cm, possibly owing to lower TOC contents (<0.9%).

Methane produced microbially is frequently observed in strongly reducing sediments, with associated minor C_{2+} concentrations 2–4 orders of magnitude lower. Several other locations in the Bransfield Strait exhibit bacterial methanogenesis in the sediments, but only under strongly reducing conditions where the interstitial dissolved sulphate has been exhausted. Dissolved sulphate in core 1140-1 showed evidence of reduction, but SO_4^{2-} persisted in large amounts throughout the core (Fig. 2), precluding bacterial methanogenesis as a source of the methane. In core 1140-1, methane contents are lower and C_{2+} contents much higher than those found in other sediments of the King George Basin exhibiting bacterial methanogenesis.

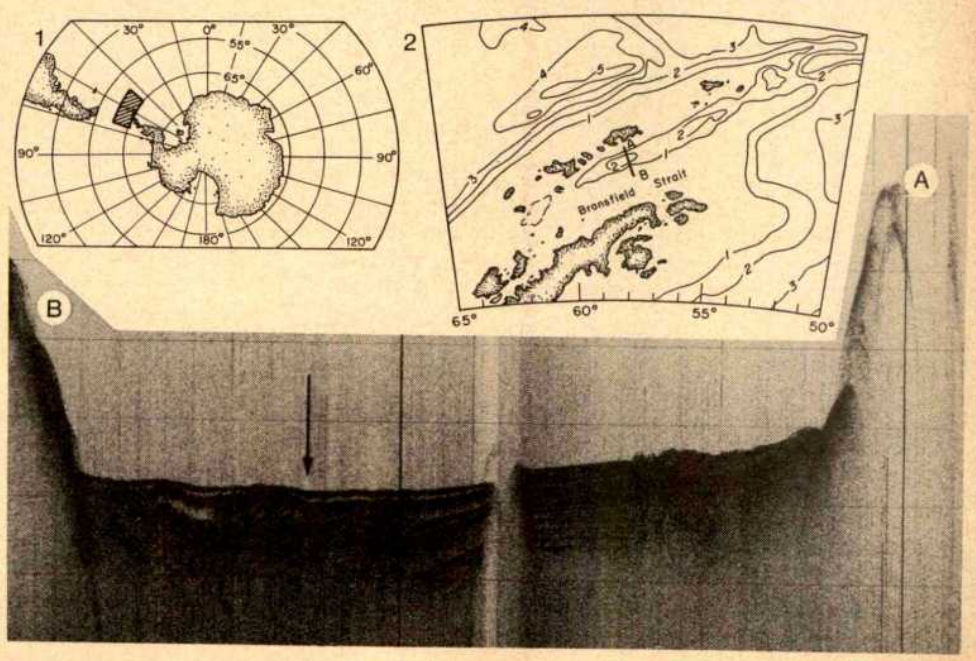

Fig. 1 Section of 3.5-kHz sediment profile showing northern (A) and southern (B) limit of King George Basin. Inset 1 is a polar projection of Antarctica showing the investigation area; inset 2 gives the bathymetry (1,000-m isobaths) and 3.5-kHz track between King George Island and the Antarctic Peninsula. Core 1140 (indicated by arrow) was taken in fine-grained turbid sequences of hemipelagic muds overlying an acoustic feature where loss of signal occurs below 5-m sediment depth. The steep basalt intrusion north of the station can be seen (centre of photo).

ND, not determined.

Carbon isotope ratios of methane and ethane were measured on the samples with higher yields and are reported in the usual δ notation relative to the PDB standard. Methane in the deeper core sections is slightly more depleted in ^{13}C (−37.1 to −39.0‰, Fig. 2) than in those nearer the surface (−31 to −35‰). Carbon isotopes of ethane were more uniformly distributed between −26.8 and −28.0‰. Thermal maturities of natural gases can be estimated using the relationship of carbon isotope ratios of methane and ethane to vitrinite reflectance[7,8]. Based on such relationships (M.J.W. and E. Faber, in preparation), the inferred maturity of the gases in the deeper core section ranges between 1.4 and 1.8% R_o (equivalent) for methane and between 1.5 and 1.7% R_o (equivalent) for ethane (Fig. 3). The good agreement between them supports the idea that the methane and C_{2+} hydrocarbons in these sediments have a similar source and thermal history. The average maturity estimate of 1.6% R_o (equivalent) of the gases places them in a late thermal stage, possibly in the condensate range.

A combination of the molecular and carbon isotope composition in the classification diagram of Bernard *et al.*[9] (Fig. 4) shows the gases to be of the late thermal associated type. The possibility of an admixture of an overcooked dry methane with an associated wet gas can be discounted because of the agreement in maturity between the C_1 and C_2 isotope data. There is no evidence of secondary alteration effects such as anaerobic oxidation in the deeper sediments. Although the low methane concentrations in the uppermost sediments may have been influenced by oxidation, the expected associated relative enrichment in C_{2+} was not observed.

The composition of solvent extracts further indicates the presence of thermal hydrocarbons in these surface sediments. The five extracted sediment samples yielded 82–320 p.p.m. (dry wt) soluble material (Table 2), which is relatively high for Recent sediments with 0.62% and 0.87% total organic carbon (TOC). The total extract/total organic carbon ratio (mg extract/g C_{org}) increases from 13 at the surface to 46 at the bottom. The lower three samples had sufficient extract for LC partitioning of which more than 50%, hetero-components and other polar compounds, was irreversibly bound to the LC column. Nevertheless, hydrocarbon concentrations are found up to 141 p.p.m. at 860 cm, which is somewhat anomalous for this diagenetic setting.

The mixture of hydrocarbons from a deeper more mature source with autochthonous bitumen is expressed most clearly in the samples from 350 and 650 cm. The saturated C_{15+} n-alkanes are dominant between C-numbers 25 and 31, apart from the deepest sample (860 cm) where phytane constitutes the major component. Where detectable, phytane is more concentrated than pristane signifying a reducing depositional environment[10] consistent with the interstitial water chemistry. n-Alkanes show an odd–even predominance (OEP) of 1.32–1.50 (Table 2), excepting the sample at 350 cm where the OEP is 1.04.

There is a relatively high contribution of rearranged steranes at 650 cm, which would not be expected in immature Recent sediments. Furthermore, the sediment from 350 cm possesses a hopane signature characteristic of many oils. In particular, the ratio of the 17-α(H)-hopane, C_{31} 22S/22R, is >1 at 350 cm (Table 2). With these exceptions, the extracts are typical of

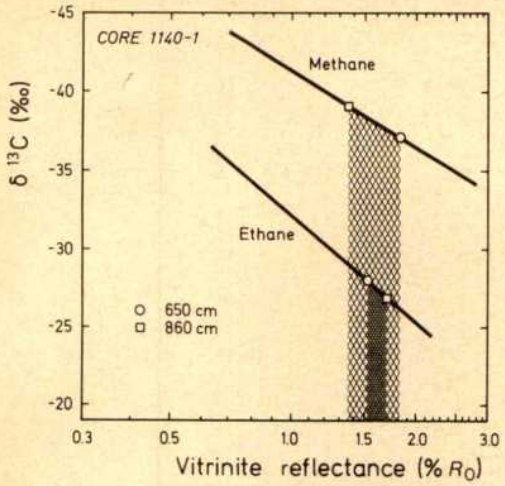

Fig. 3 Maturity of source organic matter generating the hydrocarbon gases is estimated using the empirical relationship between $\delta^{13}C$ values of C_1 and C_2 and maturation levels (M.J.W. and E. Faber, in preparation). These gases are formed in the range of the late-mature stage corresponding to a mean vitrinite reflectance of ~1.6% R_o equivalent.

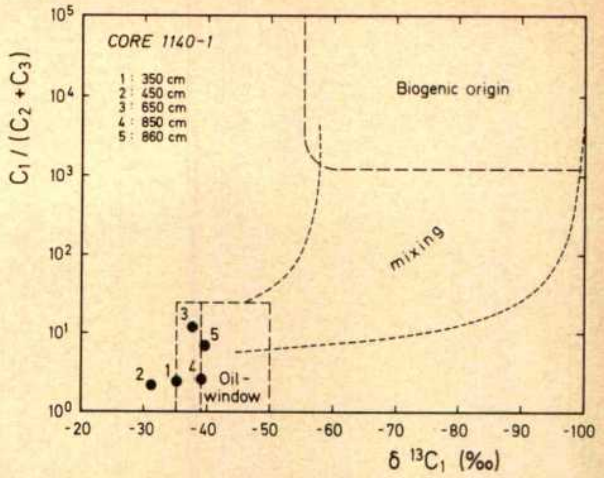

Fig. 4 Natural gas genetic classification diagram after Faber *et al.*[25] clearly showing late-stage thermal character of the hydrocarbon gases measured. There is no evidence for biogenic or mixed gases in these cored sediments.

immature organic material, with contributions of terrestrial organic material, shown by the OEP, of the higher carbon number (C_{24+}) *n*-alkane, and low contents of rearranged steranes (5-β sterane is less abundant than 5-α steranes and 20S-ethylcholestane is less than 20R-ethylcholestane). In addition, the Ts/Tm triterpane ratios (18-α(H)/17-α(H)-trisnorhopane[11]) of these samples are <1, the $C_{29}+C_{30}$ moretane contents are relatively high and C_{31}-22S of 17-α(H)-hopanes is less than C_{31}-22R (Table 2). Thus, although the degree of impregnation is somewhat low in samples at 350 and 650 cm, there are positive indications that heavier thermogenic hydrocarbons have migrated into these sediments.

The maturity of the migrated hydrocarbon component in these samples is roughly estimated by the OEP and biomarkers to be early mature ($<0.5\%$ R_o equivalent). The discrepancy between the maturity of the light hydrocarbon gases as determined by carbon isotopes (1.6% R_o equivalent) and that of the allochthonous C_{15+} hydrocarbons based on biomarkers ($<0.5\%$ R_o equivalent) and the *in situ* vitrinite reflectance ($<0.2\%$ R_o) would suggest that the gases come from more mature organic sources possibly more deeply buried than those generating the heavier bitumens. Such gases could assist in the transport of the bitumens acting for example as a solvent (compare ref. 12) The limited number of cores makes it difficult to locate the source of the hydrocarbons, or to define their regional surface expression. Coring attempts at a second station nearby (1185-1) were frustrated by basalt, but analyses of a small sample of sediment and basaltic debris remaining in the core catcher showed clear traces of C_{2+} hydrocarbon gases.

The thermogenic hydrocarbons were cored in acoustically-'turbid' horizons in the sediments of the eastern edge of the basin (Fig. 1). The cause of the acoustic turbidity is unknown. The measured light gas concentrations are not even close to the solubility limit necessary to form free gas bubbles[13] and the heavier hydrocarbons (C_{5+}) are liquid at the *in situ* pressure and temperature. In addition, the sediments cored are within the stability zone of gas hydrates[14]. If the gas contents were high enough to permit a free gas phase, this gas would be incorporated into a hydrate structure, though it is possible that gases at depths greater than those of the cored sediment may be trapped beneath, or in, hydrate caps[15]. Such preferential removal, or trapping, of the light (C_1-C_4) gases could be one explanation for the relatively high C_{5+} contents in the surface sediments. There were, however, no indications direct or indirect, of hydrates in this acoustically-turbid zone in the 3.5-kHz trace (Fig. 1). Such seismic indicators of gas hydrates are not always visible and because of the shallow coring depth (860 cm, maximum) the possibility of hydrates cannot be disregarded.

Another explanation for the absence of reflectors would be the presence of oligostromes or mud diapirs, which frequently occur in areas of rapid subsidence with undercompaction and greater heat flow. Upward-transported sediments or fluids could carry the hydrocarbon gases and even bitumens acquired at greater depth[16]; vertical fluid expulsion or flushing (mentioned above) could take place in the area of coring resulting in the decrease in bitumen and higher relative molecular mass bias ($>C_{24+}$) close to the surface, despite no change in organic facies or maturity; the lower methane concentrations in the uppermost sediments could likewise be affected. Unfortunately, surface morphology and sedimentology do not substantiate this explanation.

The King George Basin is a tectonically active zone which has extensional features such as normal dip-slip faults and basalt intrusions located close to station 1140-1 (Fig. 1, centre); higher geothermal gradients would be expected in such a geological setting. The Guaymas Basin is a comparable tectonic setting with a high geothermal gradient where hydrocarbons have been thermally generated from mature organic matter in younger than normal sediments in the proximity of intrusions[17].

Previous offshore drilling along Antarctic continental margins has been limited to Leg 28 of the Deep Sea Drilling Project in the Ross Sea and off the Shackleton Ice Sheet[18]. At three sites in the Ross Sea, minor amounts of ethane and higher homologues were measured along with substantial quantities of methane[19]. Carbon isotope data reported for the methane (−68 to −79‰) and the strong sulphate reduction at these sites[18,20] would indicate microbial methanogenesis. The contribution from thermogenic sources in this region, based solely on the molecular composition data, is uncertain. Recently, investigations on the opposite side of Antarctica, off Wilkesland, have reported bacterial gas in low concentrations, but no thermogenic gas was indicated[21].

Hydrocarbon seeps are common for most of the world's major petroleum accumulations many of which are also trapped in graben structures as in the Bransfield Strait[22]. The large-scale rift faults and igneous intrusions can create migration pathways to the surface for gaseous and liquid hydrocarbons. Several analogous cases have been reported, as for example, in California, Mexico, Sumatra and numerous locations extending along the Andes from Columbia to Terra del Fuego[23,24]. The hydrocarbon seepage in core 1140-1, however, is not on the same scale as those seeps and thus should be regarded as a micro seepage. Nevertheless, the data provide unambiguous geochemical evidence of active petroleum source rocks along the Antarctic continent.

We thank the crew and captain of the RV *Polarstern* for their support at sea under the direction of the Alfred Wegener

Senile dementia of the Alzheimer's type can be diagnosed with certainty only by examining neurofibrillary tangles and neuritic plaques under the microscope[1–4]. Recently, it has been suggested that the condition is linked to specific neurotransmitter systems[5], with a decline of cortical acetylcholine, choline acetyltransferase[5–8], cholinergic neurones projecting to the cortex[9–11], cortical noradrenaline content[12], locus coeruleus neurones[13,14] and cortical somatostatic content[15]. Using immunocytochemical methods[16], we here report that somatostatin-immunoreactive processes are present in neuritic plaques in human Alzheimer's specimens[17]. These data, as well as other reports of non-cholinergic changes[18,19], strongly imply that Alzheimer's disease cannot be linked exclusively to cortical cholinergic elements, as proposed previously[8]. Rather, our data on plaque and somatostatin co-localization and distribution patterns suggest that Alzheimer's neuropathology may involve primarily the loss of selective cortical neurones that are targets of the implicated transmitter systems and that plaque formation may result from the degeneration of presynaptic and postsynaptic neurites of large projection neurones in layers III and V. Given the neurochemically heterogeneous input to these cells, it is not surprising that several neutrotransmitter systems, one of which is somatostatin, are implicated in the pathology of Alzheimer's disease.

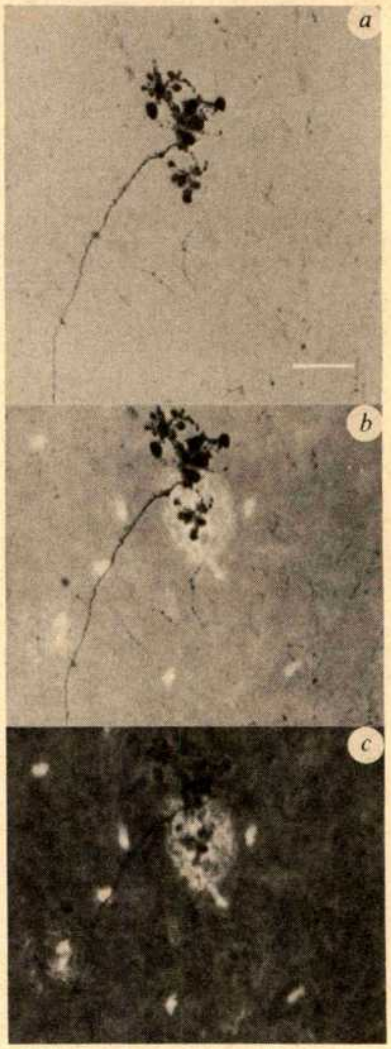

Fig. 1 Somatostatin immunoreactivity and a thioflavin-S-labelled neuritic plaque in an Alzheimer's patient: *a*, *b* and *c* describe the same microscopic field, representing the combined visualization of fluorescently labelled neuritic plaques (thioflavin-S) and somatostatin-immunoreactive profiles seen in conventional bright-field optics. *a*, Photomicrograph of this particular field in full bright field; *b*, the image obtained when viewed with fluorescence optics combined with low-intensity bright field; *c*, full fluorescence image alone. The somatostatin-immunoreactive profile (black) seems to be a cluster of degenerating boutons, many of which are bulbous and distended. In *b* and *c*, much of this pathological profile is associated with a fluorescent, amyloid-containing plaque with no clear core and thus possibly relatively immature[23,24]. Also, note that some of the bulbous profiles are outside the amyloid portion of the plaque. This complex may represent an early transitional stage where the plaque has not yet reached its full extent. Scale bar, 40 μm.

The present experiments examined normal adult, aged adult and Alzheimer cortices using antibodies against somatostatin-28 and somatostatin-28(1–12) (ref. 20). Specific cortical regions from postmortem samples of five clinically and neuropathologically confirmed Alzheimer brains and four brains from elderly patients with no neurological deficits were analysed. In some cases, sections were immunohistochemically stained to localize the prosomatostatin-derived peptides and then counterstained with thioflavin-S, a fluorescent stain that visualizes neuritic plaques and neurofibrillary tangles[21]. All Alzheimer brains contained neuritic plaques and neurofibrillary tangles in all regions stained.

In the human cortex, somatostatin antisera specific for either somatostatin-28 or somatostatin-28(1–12) show regional and laminar patterns similar to those observed in rodent cortex[16], but with a greater density of innervation. Somatostatin-positive

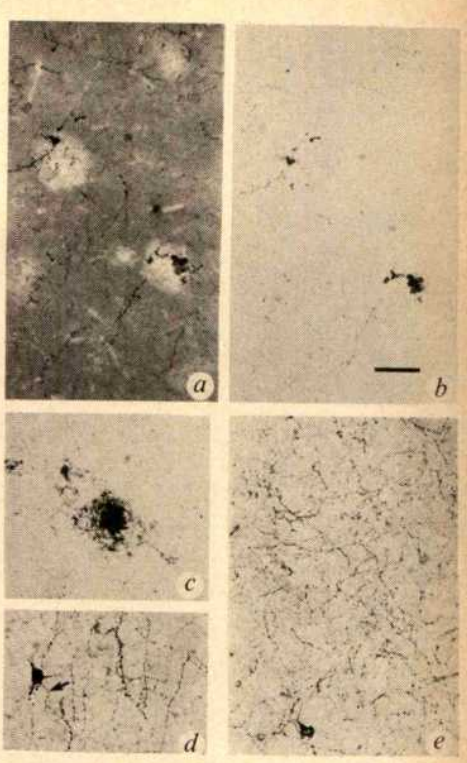

Fig. 2 Somatostatin immunoreactivity in human cortex. *a*, *b*, The same microscopic field in layer III of a section through the pre-central gyrus of a postmortem sample from an Alzheimer's patient. This section and *c* were stained immunohistochemically with S320 and counterstained with thioflavin-S. *a*, A fluorescence photomicrograph with the section exposed to fluorescence optics and low-intensity bright-field optics simultaneously. In this photograph, the fluorescent thioflavin-S-positive plaques show up as white puffs, somatostatin-immunoreactive fibres as darkly stained profiles. *b*, Exposed only to bright-field optics, thus the fluorescent plaques are not visible, but the immunoreactive diaminobenzidine-containing profiles are. Note that both of the large white plaques are associated with bulbous somatostatin-immunoreactive profiles and in both cases a labelled fibre can be seen entering the periphery of the plaque. *c*, Photomicrograph of a section stained with S320 through the superior frontal gyrus of a different Alzheimer's patient from that shown in *a* and *b*. Note the large coalescence of tangled somatostatin-immunoreactive fibres which have the appearance of a neuritic plaque; when viewed with fluorescence optics, this profile is not fluorescent and thus presumably does not contain amyloid. *d*, *e*, Photomicrographs of sections stained with 320, from postmortem samples of the frontal lobe of a neurologically normal 82-yr-old female. In *d*, the arrow points to a putative axon emerging from a labelled cell in layer III tentatively identified as a basket cell[16,26]. *e*, Normal density of somatostatin-immunoreactive fibres in layers II and III of frontal lobe from the same patient. Note the presence of highly arborized, varicose fibres. The cortical regions studied were the superior frontal gyrus, parahippocampal and inferior temporal gyrus, superior temporal gyrus, anterior cingulate gyrus, precentral gyrus, post-central gyrus and striate cortex.

Methods. Human tissue was obtained 4–16 h postmortem, immersed in fresh 4% paraformaldehyde phosphate buffer (*p*H 7.4) for 5 days, followed by graded sucrose solutions (12–18%) for several days and then sectioned by cryostat (40-μm sections). The sections, pretreated in 1% hydrogen peroxide for 15 min to remove intrinsic peroxidase activity[14], were stained immunohistochemically as reported previously[16], with antisera 309 and 320, immunochemically characterized previously[20]. S309 is directed against the N-terminal 12 amino acids of somatostatin-28 and thus recognizes both somatostatin-28 and somatostatin-28(1–12). The antigenic determinant of S320 is the C-terminus of somatostatin-28(1–12). The Glu-OH at the carboxy-terminus of the molecule is crucial for antigenicity so that neither somatostatin-28 or somatostatin-14 is read. Any N-terminal extension of somatostatin-28(1–12) will be recognized by S320 (see refs 16, 20). The tissues were then stained with thioflavin-S which has been shown to stain amyloid-containing profiles[21]. To stain with thioflavin-S, mounted tissue sections were hydrated in distilled H_2O for 10 min, followed by immersion in a filtered aqueous 1% thioflavin-S solution for 10 min. Sections were then differentiated and dehydrated through a series of alcohols (70% absolute) into xylene and coverslipped in Permount (Fisher). The tissues were viewed with a Zeiss microscope equipped for both fluorescence and bright-field optics. Scale bar in *b*, 60 μm (applying to all photomicrographs).

cell bodies and terminals exhibit a bilaminar distribution; for example, there are few labelled cells or fibres in layer IV, but much higher densities of labelled cells in layers II, superficial III and VI. In the human cortex, the terminal field in layer I is even denser than in rat cortex; there are also labelled cell bodies in the subcortical white matter[17,22]. Human cortex, compared with rat cortex, has a much greater degree of regional variation in density of somatostatin-positive staining. The cingulate, temporal and frontal cortices have the densest somatostatin-positive terminal arborization of all neocortical regions; parietal cortex has an intermediate density and the primary visual cortex has the least dense innervation.

The general regional and laminar patterns of somatostatin immunoreactivity for terminals and cell bodies in Alzheimer cortices were similar to those in postmortem samples from normal elderly patients with no clinical or autopsy signs of Alzheimer's disease. All Alzheimer specimens, however, contained striking evidence of direct pathological involvement of somatostatin-containing cortical neurones. Swollen bulbous profiles interpreted as degenerating somatostatin-positive fibres (Figs 1, 2*a*, *b*), were readily apparent. With combined fluorescence bright-field optics, immunohistochemical material counterstained with thioflavin-S further revealed that these bulbous, clustered, swollen profiles were associated often with amyloid-containing neuritic plaques. Most of the plaques containing somatostatin-immunoreactive material appeared to be relatively 'immature', with no clear amyloid core. However, 'mature' plaques with a clear amyloid core and apparently degenerating somatostatin-positive profiles at the core perimeter were also observed. In addition, non-bulbous, somatostatin-positive fibres with a normal varicose appearance were seen often to surround or end just inside the periphery of mature plaques. Depending on the region and layer examined, 30–50% of the definitive early and mature plaques contained some somatostatin immunoreactivity. This percentage is surprisingly high for co-localizations based on single sections of plaques. Reconstruction of the entire three-dimensional extent of plaques would probably reveal an even higher proportion. Moreover, compared with perfused monkey cortex, only a fraction of somatostatin profiles are revealed in postmortem Alzheimer's material. Finally, despite lacking thioflavin staining for amyloid, other presumptively degenerating bulbous somatostatin-immunoreactive profiles could represent a stage of plaque formation where amyloid deposition is minimal, as in primitive plaques[23,24]. Indeed, some deteriorating somatostatin-immunoreactive profiles resemble clearly the primitive plaque of classical neuropathology (see Fig. 2*c*). Profiles similar to those seen in Alzheimer cases (Fig. 2) were seen rarely in normal aged cortices. Future experiments will aim at determining whether or not a given plaque contains multiple neurotransmitter markers.

The laminar and regional distributions of Bielschowsky-stained and thioflavin-positive plaques in Alzheimer material bear a striking similarity to distributions of somatostatin-positive terminals in normal human and animal material[17]. Most of the plaques in Alzheimer's specimens, like somatostatin-positive terminals in normal specimens, are in the supragranular layers, particularly layer III, with layer V having intermediate density and layer IV the lowest density of plaques and somatostatin innervation. Most of the somatostatin-positive plaque complexes (see Figs 1, 2*a*, *b*) are in layer III, where neurone loss in Alzheimer's disease is maximal[25] and most of the cortico-cortical association systems originate. In addition, plaque density in Alzheimer's material and somatostatin-terminal density in normal material show an almost identical regional profile: cingulate, frontal and temporal regions have the highest density of plaques and somatostatin-immunoreactive terminals, parietal cortex has an intermediate density of both and the primary visual cortex has the lowest of both. Thus, the limbic and association areas of the cortex, which are dominated by cortico-cortical association systems rather than thalamo-cortical connections, are the areas with the highest plaque density[26] and somatostatin

innervation. Collectively, these laminar and regional data suggest that plaque formation and somatostatin innervation are linked to similar elements of cortical circuitry. Plaques may arise from the degeneration of a complex of the postsynaptic neurites of large layer III or V projection neurones which form the cortical association systems[27] and their associated inputs containing neurotransmitters such as acetylcholine, noradrenaline, somatostatin or substance P[28].

The combined neurochemical and neuropathological findings in Alzheimer specimens lead to the hypothesis that functional deficits may result from the breakdown of both neocortical association systems and divergent, global cortical afferents such as the cholinergic projection from the nucleus basalis and the noradrenergic projection from the nucleus locus coeruleus. Whether the degeneration of these ascending systems is primary or secondary to a primary intra-cortical pathology, the breakdown of these global afferent systems plus a breakdown of the cortico-cortical associational systems could give rise to profound loss in attention, arousal and intellectual function, with minimal effects on specific sensory or motor performance. In this view, Alzheimer's disease could represent a dissociation of the various components of those cortical functions subserved by distributed systems[29]. The multiple transmitter systems involved in the pathological process suggest that no single transmitter can provide a therapeutic strategy and that the nature of the primary pathological insult remains the main question.

We thank Dr U. De Girolami and Dr R. Nakamura for pathological analysis of the Alzheimer's and normal human material. Location of neuronal tangles in somatostatin neurones in Alzheimer's disease

G. W. Roberts*, T. J. Crow* & J. M. Polak†

* Division of Psychiatry, Clinical Research Centre, Harrow, Middlesex HA1 3UJ, UK
† Department of Histochemistry, Hammersmith Hospital, London W12 0HS, UK

Senile dementia of the Alzheimer type is a chronic, progressive neuropsychiatric condition characterized clinically by global intellectual impairment[1] and neuropathologically by the presence of numerous argyrophilic plaques and tangles[2–4]. Neurochemical investigations have established loss of the cholinergic[5,6] and aminergic[7,8] projections to the cerebral cortex and a loss of the content of somatostatin[9–12], with preservation of cholecystokinin[11,13] and vasoactive intestinal polypeptide[11,14], neuropeptides also located in cells intrinsic to the cortex. We describe here the relationship between cortical somatostatin immunoreactivity and the plaques and tangles of diseased tissue by immunocytochemical and silver impregnation techniques on paraffin-embedded tissue. In sections of Alzheimer's tissue, cortical somatostatin-immunoreactive perikarya exhibited morphological changes consistent with neuronal degeneration. Silver-stained material immunostained subsequently showed that many neurones containing tangles were also somatostatin positive. No such co-localization was observed using antisera to other neuropeptides. Our findings indicate that a subclass of somatostatin-positive neurones are affected selectively in Alzheimer's disease and that these neurones also contain neuronal tangles. Thus, destruction of somatostatin-containing neurones is an early and perhaps critical event in the disease process.

Brains were obtained postmortem from six controls (4 males, 2 females, mean age 76 yr, range 58–87 yr) and 15 clinically and neuropathologically defined cases of Alzheimer's (5 male, 10 female, mean age 77 yr, range 57–91 yr). Brains were fixed routinely in 4% formalin and blocks of tissue which included the left temporal lobe structures (temporal cortex, hippocampus, amygdala) were taken and paraffin embedded, then 20-μm coronal sections cut for histological examination. Plaques and tangles were demonstrated using a modified Palmgren's method[15], somatostatin and other neuropeptides by immunocytochemical techniques (see Fig. 1 legend for details).

In control tissue, somatostatin immunoreactive neurones were numerous in temporal and entorhinal cortex and parahippocampal gyrus (Fig. 1*a*). The neurones were localized in cortical layers II–III and V–VI and were predominantly of the non-pyramidal type (multipolar and bitufted; see Fig. 1*b*), showing a range of morphological diversity. Numerous somatostatin fibres were also observed running radially with some lateral branching towards the pial surface and down to the subcortical white matter. Many somatostatin-positive neurones were found adjacent to the subcortical white matter with their dendritic fields oriented parallel to it; fibres from these cells penetrated into the white matter, possibly to form part of an intracortical association system. Somatostatin-positive neurones and fibres were also observed in the subiculum, pro-subiculum, hippocampal CA1–4 (stratum oriens and pyrimidale), the hilus of the dentate gyrus and the latero-basal, central, medial and cortical nuclei of the amygdala. Large numbers of multipolar (Golgi type II) neurones and fibres were also observed in the caudate nucleus and putamen (Fig. 1*c*).

On immunohistochemical examination, Alzheimer's cases showed marked decreases in somatostatin content. In the superficial layers (II and III) of the temporal cortex, parahippocampal gyrus and uncus, both neuronal and fibre staining was depleted substantially; some regions showed no observable immunoreactive neurones and had a concomitant decrease in local fibre innervation. In addition to the decreases in immunoreactive material, many somatostatin-positive cells (particularly in deeper cortical layers) were observed which showed morphological changes consistent with neuronal degeneration and

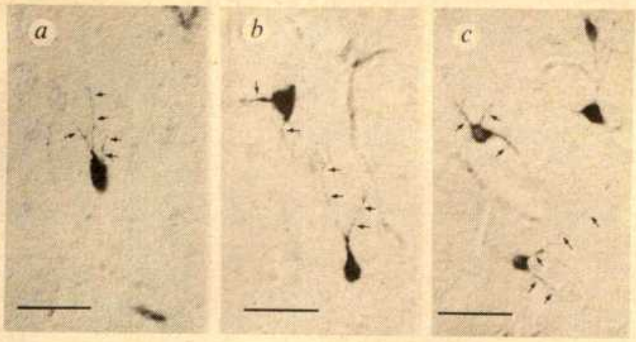

Fig. 1 Somatostatin-28(1-14 Tyr)-immunoreactive neurones in control tissue. *a*, Typical bitufted cell-type observed frequently in cortical layers II-V with dendrites oriented towards the pial surface (arrows). Different morphological subtypes of neurones are seen in the cortex. *b*, Multipolar cell with laterally extending dendrites (arrowed) in close proximity to a bitufted neurone with radially extending dendrites (arrowed) in layer III of the cortex. *c*, Example of the medium-sized aspiny (Golgi type II) somatostatin-immunoreactive interneurones found throughout the caudate. Each cell has two to four processes (arrowed) which curve as they course away from the cell body. Scale bars, 50 μm.

Methods. Sections used for the co-localization of tangles and somatostatin immunoreactivity were processed first for silver impregnation, rinsed in phosphate buffer and processed subsequently for immunocytochemistry. For silver impregnation, sections were processed according to the protocol of Cross[15]. For immunocytochemistry, 20-μm sections of tissue were incubated overnight with specific antisera raised to: somatostatin-28(1-14 Tyr) (RIA), dilution 1/1,000: somatostatin-14 (ref. 16), dilution 1/2,000; vasoactive intestinal polypeptide, dilution 1/10,000 (ref. 19); cholecystokinin-octapeptide, dilution 1/500 (ref. 19) and neuropeptide Y, dilution 1/1,000 (ref. 17) according to a previously described protocol for the peroxidase/anti-peroxidase method[16]. Pre-absorption of the diluted somatostatin-28(1-14 Tyr) antiserum with 50 μg somatostatin-28(1-14 Tyr) abolished all specific staining; pre-absorption of the antibody with other peptides had no effect. Specificity details of the other antisera used have been given elsewhere[16,17]. The antiserum raised to somatostatin-28(1-14 Tyr) gave much more intense staining of cell bodies, dendrites and fibres than the antiserum raised to somatostatin-14 (in agreement with the reports of Morrison *et al.*[38] for the rat brain). Therefore, the data reported here are obtained using the somatostatin-28(1-14 Tyr) antiserum.

analogous to those obtained in silver-impregnated sections (Fig. 2); these degenerate morphological profiles were present in hippocampal areas (subiculum, CA1 and hilus of dentate gyrus) and the amygdala (primarily medial and cortical nuclei). Conversely, somatostatin immunoreactivity in the basal ganglia (caudate nucleus and putamen) was unchanged, with normal degrees of fibre innervation and no evidence of neuronal degeneration. In silver-impregnated sections which were subsequently immunostained, neurones with argyrophilic tangles were often somatostatin-positive (Fig. 3). These silver/somatostatin-positive structures (SSPS) were observed in the hippocampus (Fig. 3*a*, *c*) cortical areas (layers II and III, less often in layers V and VI; Fig. 3*b*) and amygdala. In all cases, careful scanning revealed somatostatin-positive neurones which were not degenerate or impregnated with silver (sometimes in the middle of clusters of SSPS) and tangles unstained for somatostatin (Fig. 3*c*). No specific relationship was discernible between plaques and somatostatin-positive structures. Occasionally some plaques seemed to be associated closely with somatostatin-positive fibres.

To establish the specificity of the relationship between somatostatin-positive cells and tangles, additional sections were processed for immunocytochemistry or for silver impregnation followed by immunocytochemistry using specific antibodies to cholecystokinin-octapeptide, vasoactive intestinal polypeptide[16] and neuropeptide Y[17] (all present in intrinsic cortical neurones). Fibres containing these peptides were associated with plaques. None of these peptides was decreased in Alzheimer's disease, co-localized with neuronal tangles or displayed appreciable

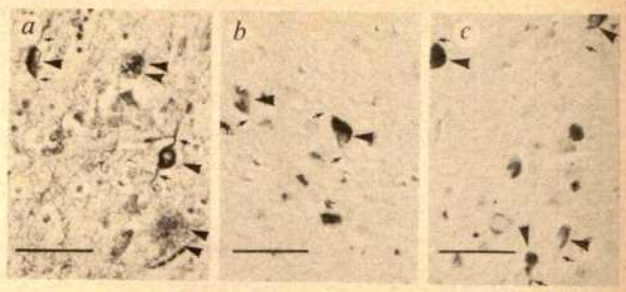

Fig. 2 *a*, Silver-impregnated section of temporal cortex showing typical tangles (single arrowhead) and plaques (double arrowheads) in a case of Alzheimer's disease. Note how dendrites of tangles are thickened and degenerate. *b*, Degenerate neuronal profiles of somatostatin-28-immunoreactive neurones in temporal cortex (layer III) of the Alzheimer's case (arrows). Note degenerating dendrites with almost total absence of staining (small arrows). *c*, Degenerate somatostatin-28-positive neurones in subiculum of hippocampus (arrows). Note presence of degenerating dendrites (small arrows). Scale bars, 50 μm.

numbers of conspicuously abnormal morphological profiles (Fig. 3*d*), with one partial exception. In the most severely affected cases (judged by neuropathological criteria), some neuropeptide Y-containing neurones in deeper cortical layers were degenerate and co-localized with neuronal tangles. In some cortical and subcortical neurones, neuropeptide Y is colocalized with somatostatin[18,19]. However, neuropeptide Y content is largely unchanged in Alzheimer's disease[23]; thus, the observed degeneration may be a late change. These results agree with radioimmunoassay studies demonstrating (1) that somatostatin concentrations are higher in the temporal than other cortices and (2) that although somatostatin is decreased in Alzheimer's disease, other peptides (including neuropeptide Y) are relatively unaffected[11,13,14,20].

Both plaques and tangles are related quantitatively to dementia scores[21-23]; both indices of pathology are also associated with the decreases in choline acetyltransferase (CAT) in the frontal and temporal cortex[21-24]. Indeed, reports of CAT and acetylcholinesterase staining in plaques has led to the proposal that plaques are composed of (at least in part) degenerating cholinergic terminals[25]. The relationship between plaques and CAT has prompted studies on the basal nucleus of Meynert—the source of almost all the cortical cholinergic innervation. This nucleus shows considerable cell loss and/or atrophy in Alzheimer's disease, as do the cell bodies of origin of the monoaminergic projections to the cerebral cortex, for example, the locus coeruleus[26-28]. These findings have prompted speculations that Alzheimer's is a disease of the isodendritic core[29], the primary lesion being subcortical (and cholinergic) and the cortical pathology resulting from transynaptic degeneration caused by the loss of ascending fibres. Therefore, the plaques and tangles are viewed "as a secondary response to the loss of ascending inputs"[29]. If this were correct, a loss of neurones in the basal nucleus of Meynert would lead to a drop in cortical CAT and somatostatin. In rats, lesions to the basal nucleus of Meynert do lead to cholinergic deficits but cortical somatostatin levels remain unchanged[30]. Conversely, lesions of the cortex (which produce somatostatin losses along with losses of other intrinsic transmitters in both rats and man) result in retrograde degeneration of cholinergic cells in the basal nucleus of Meynert similar to that seen in Alzheimer's disease[31,32]. These reports and the correlations between cortical pathology and symptoms imply that the cortex is the seat of pathology and that, in particular, the temporal cortex is the main focus of the disease process. The findings reported here that some plaques (which may include degenerating cholinergic terminals) contain somatostatin fibres (confirming a previous observation)[33] and reports that plaques also contain dendrites and axons of diverse local neurones and perhaps glial elements[34] indicate that plaques may be a neurochemically nonspecific consequence of the disease process.

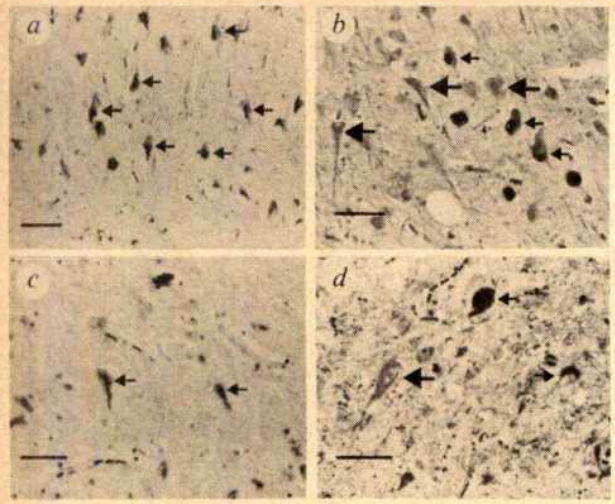

Fig. 3 Silver-stained sections (in which tangles stain black) were immunostained subsequently to detect the presence of somatostatin immunoreactivity (dark precipitate). In these sections many silver/somatostatin-positive structures (SSPS, dark staining) are seen in temporal regions in Alzheimer's cases. *a*, The subiculum of the hippocampus showed numerous SSPS (arrowed) as did *b*, neurones (arrowed) in layers II, III and V of the parahippocampal gyrus. *c*, The CA1 pyramidal region of the hippocampus also contained many SSPS (small arrows); it was observed often that even in regions which showed numerous SSPS, apparently normal somatostatin-28-positive neurones could still be observed (large arrows). *d*, Staining with antiserum to other peptides, for example vasoactive intestinal peptide, demonstrated that in the cortex, tangles (small arrows) did not occur in vasoactive intestinal peptide-immunoreactive neurones (large arrow). Scale bars, 50 μm.

The findings demonstrate a strong link between the formation of neuronal tangles (their presence highly correlated with the symptoms of dementia) and the decrease of immunoreactivity to somatostatin (the only intrinsic cortical transmitter known to be affected) in the temporal cortex (pathologically the area most affected). We suggest that somatostatin neurones in the temporal cortex are a primary focus for the disease process and that the loss of somatostatin content is an early event in the production of symptoms and the subsequent (or concomitant) cortical atrophy. The cholinergic deficit and atrophy of the basal nucleus of Meynert may be a secondary consequence of the loss of cortical somatostatin neurones from a region which provides the major input to the basal nucleus[35]. The reason for the selectivity of the disease process is unknown but presumably is related to the physiological properties of susceptible somatostatin neurones in the cortex. The structure of somatostatin itself (particulary the helical fibril-forming noncyclic form[36]) or the recently described somatostatin gene[37] may be relevant.

We thank Professor J. A. N. Corsellis and Ms R. Brown at Runwell Hospital for the provision of material. This work was supported by the MRC and the Research Reagent Programme of RIA UK Ltd.

A functional correlate for the dihydropyridine binding site in rat brain

D. N. Middlemiss & M. Spedding

Merrell Dow Research Institute, Strasbourg Centre, 16 rue d'Ankara, 67084 Strasbourg Cedex, France

Calcium channels, controlling the influx of extracellular Ca^{2+} and hence neurotransmitter release, exist in the brain[1]. However, drugs classed as calcium antagonists and which inhibit Ca^{2+} entry through voltage-activated Ca^{2+} channels in heart and smooth muscle[2], seem not to affect any aspect of neuronal function in the brain at pharmacologically relevant concentrations[3–6]. Yet the dihydropyridine calcium antagonists (for example, nitrendipine) bind stereospecifically with high affinity to a recognition site on brain-cell membranes thought to represent the Ca^{2+} channel[4,7,8] and consequently, the physiological relevance of these sites has been questioned[9]. However, activation of voltage-dependent Ca^{2+} channels can increase cytoplasmic Ca^{2+} and neurotransmitter release in neuronal tissue[10]. We show here that Bay K 8644, a dihydrophyridine Ca^{2+}-channel activator[11,12], can augment K^+-stimulated release of serotonin from rat frontal cortex slices and that these effects can be antagonized by low concentrations of calcium antagonists. As ^{3}H-dihydropyridine binding to cortical membrane preparations resembles the binding in heart and smooth muscle where there are good functional correlates[8,13] we conclude that the dihydropyridine binding sites in the brain represent functional Ca^{2+} channels that can be unmasked under certain circumstances.

We have used K^+-induced depolarization of rat cortical slices to stimulate Ca^{2+} entry and evoke ^{3}H-serotonin release from the cortical serotonergic neurones as a functional correlate of the dihydropyridine binding site in brain tissue. Slices of the rat frontal cortex were incubated in Krebs medium with ^{3}H-serotonin to label specifically the neurotransmitter stores in serotonergic nerve terminals. The slices were then superfused with physiological medium and exposed to two stimuli of Krebs medium containing elevated K^+ (25 mM). The first stimulus (S_1) occurred 38–42 min after the start of the superfusion and the second (S_2) at 78–82 min. ^{3}H-serotonin release is coupled closely to Ca^{2+} entry[14] and K^+-evoked release in our experiments was entirely Ca^{2+} dependent. Drugs (when present) were added at $t = 58$ min and their effects quantified by the standard method of comparing the efflux of radioactivity evoked by the first K^+ stimulus with that evoked by the second K^+ stimulus (S_2/S_1 ratio). Effects on basal release rates were quantified by measuring the ratio of basal outflow immediately before S_1 compared with that immediately before S_2.

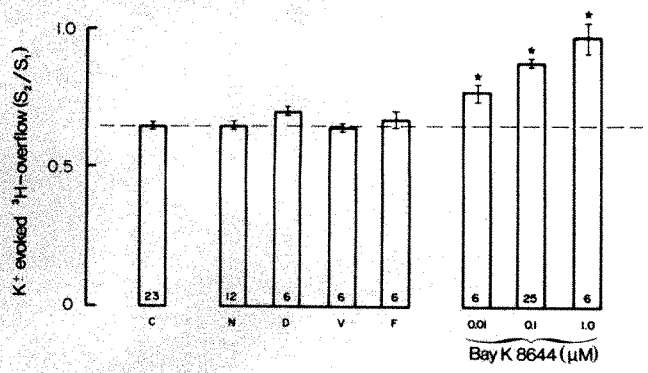

Fig. 1 Effect of calcium antagonists and Bay K 8644 on K^+-evoked release of ^{3}H-serotonin from rat frontal cortex slices. C, control; N, nifedipine (1 μM); D, diltiazem (1 μM); V, verapamil (1 μM); F, flunarizine (1 μM).

Methods. The frontal cortices from two male Sprague–Dawley rats (200–250 g) were dissected rapidly and chopped in two directions at 250 μm on a McIlwain brain-tissue chopper. The slices (total tissue weight 200–250 mg) were incubated for 15 min at 37 °C in 5 ml Krebs/Ringer-bicarbonate solution (composition (mM): NaCl 135, KCl 5, $NaHCO_3$ 25, $MgSO_4$ 1, KH_2PO_4 1.25, $CaCl_2$ 2, glucose 10; gassed with 95% O_2 and 5% CO_2) containing 0.1 μM ^{3}H-serotonin (specific activity 28.3 Ci mmol^{-1}) and 10 μM pargyline. After three washes with 5 ml Krebs buffer, 50-μl aliquots of the slices (~20 mg tissue) were transferred to each chamber (100 μl vol) of a superfusion apparatus and superfused at a rate of 0.38 ml min^{-1} with Krebs buffer containing 3.2 μM paroxetine to prevent the re-uptake of serotonin into the nerve endings. After 30 min superfusion ($t = 30$ min), 18 successive 4-min fractions were collected ($t = 30$ to $t = 102$ min). The slices were exposed to two separate 4-min stimuli by Krebs buffer containing 25 mM K^+ ions (isosmolar replacement of NaCl by KCl) starting at $t = 38$ and 78 min. Drugs were added to the superfusate at $t = 58$ min and were present throughout the rest of the superfusion period. After the radioactivity in the fractions and that remaining in the tissue slices had been determined by liquid scintillation counting, the fractional efflux rate of each fraction was determined. The magnitude of the efflux evoked by the first stimulus (S_1) was then compared with that evoked by the second stimulus (S_2) by measuring the additional efflux evoked by the 25 mM K^+ Krebs during the time period $t = 38$–58 min (S_1) and 78–98 min (S_2). For the purpose of this calculation, a linear decline in the efflux of ^{3}H was assumed between $t = 38$–62 min and $t = 78$–102 min for the calculation of S_1 and S_2 respectively. At $t = 42$ min, control basal release rates in the absence of added drugs were 0.71 ± 0.02% tissue stores per min (mean ± s.e.m., $n = 29$). The additional release evoked by the first 4-min exposure to 25 mM K^+ Krebs (S_1) was 10.20 ± 0.48% tissue stores ($n = 29$) and to the second exposure (S_2) 6.72 ± 0.36% tissue stores ($n = 29$). Drug effects were quantified by calculating the S_2/S_1 ratio. Results are mean ± s.e.m. Numbers in the histograms indicate the number of separate experiments. Statistical significance of drug effects compared with controls was assessed using a two-tailed Mann–Whitney U test ($^*P < 0.05$).

Although the K^+-evoked ^{3}H-serotonin release was entirely Ca^{2+} dependent, a range of calcium antagonists with disparate structures and different sites of action did not affect ^{3}H-serotonin release at concentrations which cause considerable antagonism at Ca^{2+} channels in smooth muscle preparations[15] (Fig. 1). This lack of effect on K^+-evoked release was accompanied by a small but non-significant enhancement of basal ^{3}H release, consistent with the negligible effects of calcium antagonists on neurotransmitter release reported previously[5,6].

Bay K 8644 both activates Ca^{2+} channels[11,12] and increases rather than antagonizes Ca^{2+} entry[16]. It binds to the dihydropyridine recognition site and, in the rat cortex, displaces ^{3}H-nimodipine binding with a K_i of 30 nM (ref. 17). Basal release of ^{3}H-serotonin from rat frontal cortex slices was not modified significantly by Bay K 8644 (0.01–1 μM), but K^+-evoked serotonin release was augmented in a concentration-dependent manner (0.01–1 μM; Fig. 1). Thus, in the presence of 1 μM Bay 8644, the S_2/S_1 ratio was 0.97 ± 0.06 ($n = 6$), an

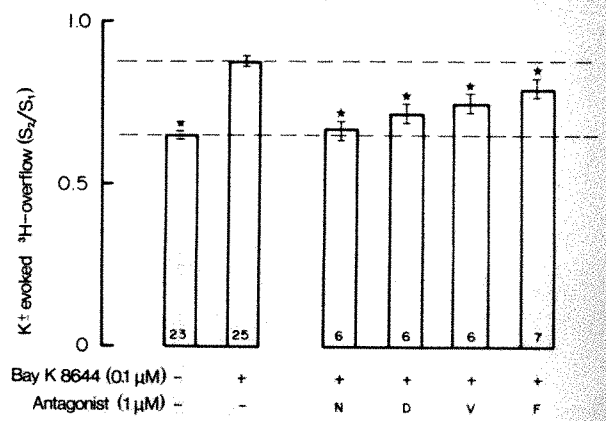

Fig. 2 Effect of calcium antagonists on the augmentation of K^+-evoked release of ^{3}H-serotonin from rat frontal cortex slices by Bay K 8644. N, nifedipine; D, diltiazem; V, verapamil; F, flunarizine. Experiments were performed as described in Fig. 1 legend. Bay K 8644 (0.1 μM) and the relevant antagonist (1 μM) were added to the superfusion medium at $t = 58$ min and were present throughout the rest of the experiment. Results are mean ± s.e.m. Numbers in the histograms indicate the number of separate experiments. Statistical significance of effects, compared with Bay K 8644 alone, were assessed using a two-tailed Mann–Whitney U test ($^*P < 0.05$).

increase of 49% above the control value ($S_2/S_1 = 0.65 \pm 0.01$; $n = 23$). In this respect the effects of Bay K 8644 on ^{3}H-serotonin release resemble the effects on K^+-induced contractions in smooth muscle, where the compound increases tone only when the Ca^{2+} channels are stimulated by K^+-depolarization[12]. Furthermore, the concentrations of Bay K 8644 required to augment ^{3}H-serotonin release were similar to those required to displace ^{3}H-nimodipine binding in this tissue[17]. A submaximal concentration of Bay K 8644 (0.1 μM), which increased the S_2/S_1 ratio by 35% (S_2/S_1 ratio in the presence of 0.1 μM Bay K 8644 = 0.88 ± 0.02; $n = 25$), was chosen to investigate antagonist interactions.

The concentrations of the calcium antagonists which had no effect on K^+-evoked ^{3}H-serotonin release attenuated the stimulant effects of Bay K 8644 (Fig. 2). These concentrations have been shown to block Ca^{2+}-induced contractions in smooth muscle in the presence of Bay K 8644 (ref. 18); however, these concentrations are sufficiently low to exclude effects on ion channels other than the Ca^{2+} channel[2].

This interpretation is supported by experiments showing that the augmentation of K^+-evoked release induced by the serotonin autoreceptor antagonist methiothepin was not attenuated by nifedipine. Thus, methiothepin (0.3 μM added after S_1) increased the S_2/S_1 ratio to 0.94 ± 0.05 (mean ± s.e.m.; $n = 6$) and a similar agumentation was also seen if nifedipine (1 μM) was added to the superfusate at the same time as the methiothepin (S_2/S_1 ratio 1.02 ± 0.06; not significant against methiothepin alone; $n = 6$). The stimulant effects of Bay K 8644 can therefore be attributed to stimulation of voltage-dependent Ca^{2+} channels which, in the presence of this activator, resemble those in smooth muscle cells[18] or in cells derived from the adrenal glands[19–22] in their susceptibility to organic calcium antagonists. Previous studies using tissues derived from sources other than the brain give conflicting evidence about the effects of Bay K 8644 on transmitter release[15,22,23]. The reasons for these differences are not yet understood, but may reside in the nature of the different stimuli used to release the transmitters. Thus, Bay K 8644 can augment K^+-evoked release of catecholamines from chromaffin tissue[19,22] but not noradrenaline release from sympathetic neurones evoked by supramaximal electrical stimulation[23]. We have observed that Bay K 8644 (0.1 μM) failed to augment K^+-evoked release of ^{3}H-serotonin from rat frontal cortex slices when the K^+ stimulus was increased to 50 mM (data not shown). We therefore consider that Bay K 8644 will only augment neurotransmitter release in conditions of submaximal stimulation. Nevertheless, our experiments have shown clearly that

Ca^{2+} channels in the brain differ from those in the heart and smooth muscle because they become sensitive to organic calcium antagonists only in the presence of Bay K 8644. One explanation for these apparent differences between central and peripheral Ca^{2+} channels may result from the recent discovery that Ca^{2+} channels comprise several subunits[24-26] differentially affected by organic calcium antagonists[27]. It is therefore possible that the subunits of the Ca^{2+} channel in nervous tissue are arranged differently from those in smooth muscle and the presence of Bay K 8644 is required to induce a conformational change, not only activating the channels but also conferring sensitivity to the antagonists. Such an effect could have important consequences if neuronal Ca^{2+} channels could be activated similarly in physiological or pathological conditions. Thus, calcium antagonists would have little effect on normal neuronal function but may cause marked inhibition of excess Ca^{2+} entry following certain stimuli. Such stimuli may occur in pathological conditions as the anoxia-induced noradrenaline release from nerves in the heart is susceptible to calcium antagonists[28].

Thus, dihydropyridines have a defined functional role in the control of neurotransmitter release, affecting release at similar concentrations to those at which they bind to neuronal tissues[17] and to those at which they affect smooth muscle cells[18]. The striking effects of Bay K 8644 in our experiments suggest that this Ca^{2+} channel activator will prove a useful tool with which to evaluate the functional effects of calcium antagonists in the brain.

We thank Martine Schneider for technical assistance, Claudine Kratz for typing the manuscript and Dr M. Schramm (Bayer A.G.) for the supply of Bay K 8644.

Identification of a distinct synaptic glutamate receptor on horizontal cells in mudpuppy retina

Malcolm M. Slaughter

The separation of ON and OFF channels and the development of an antagonistic surround occur at the first synapse in the vertebrate retina[1-3]. This functional differentiation is mediated by the action of the photoreceptor neurotransmitter on the ON bipolar, OFF bipolar and horizontal cells, respectively. Glutamate mimics the action of the photoreceptor transmitter on all second-order neurones in fish[4,5], amphibian[6] and mammalian[7] retinas. The diversity of cellular responses produced by one neurotransmitter raises the possibility of multiple postsynaptic receptor–ionophore complexes. We reported previously that one glutamate analogue, 2-amino-4-phosphonobutyrate, reveals that the ON bipolar synaptic receptor is pharmacologically different from those of other second-order neurones[8,9]. The results presented here demonstrate that another glutamate analogue, D-*O*-phosphoserine, selectively antagonizes the synaptic responses of horizontal cells. Taken together, these findings indicate that there are three glutamate-like receptor subtypes in the outer retina and suggest a correlation between receptor subtype and the physiological properties of second-order neurones.

Experiments were performed on the superfused retina-eyecup preparation of the mudpuppy, *Necturus maculosus*. The hemisected eyecup was superfused with amphibian Ringer's solution (111 mM NaCl, 2.5 mM KCl, 1.8 mM $CaCl_2$, 1 mM $MgCl_2$, 10 mM dextrose, 5 mM HEPES, *p*H 7.80) to which pharmacological agents could be added. Standard intracellular electrophysiological techniques were used to evaluate the effects of drugs on the light-driven synaptic responses of second-order neurones. A complete description of the methodology has been published previously[6,10].

Glutamate analogues such as kainic acid and quisqualic acid mimic the action of the photoreceptor neurotransmitter on all mudpuppy second-order neurones[6]. In the present experiments, we examined the effects of the D form of a glutamate analogue, *O*-phosphoserine, on exogenously applied glutamate analogues and on the endogenous photoreceptor neurotransmitter. When the retina was superfused with 5 mM D-*O*-phosphoserine, photoreceptor light responses were unchanged or only slightly enhanced. However, the drug had a selective effect on synaptic transmission between photoreceptors and second-order neurones. The photoreceptor neurotransmitter is released maximally in the dark, causing horizontal cells to be depolarized[11-13]. Figure 1*a* shows that D-*O*-phosphoserine at 2.5 mM hyperpolarized the 'dark' membrane potential of the horizontal cell and diminished the light response by 50%, consistent with a blocking of the photoreceptor neurotransmitter. Both small spot- and annulus-evoked responses were similarly affected, and the antagonism was dose-dependent over the range 1-10 mM. In contrast to this action of D-*O*-phosphoserine on horizontal cells, the direct synaptic communication between photoreceptors and bipolar cells was not diminished by the drug. Figure 1*b* shows that the 'centre' response of OFF bipolars to small-spot or annular stimulation remained essentially unaltered during a relatively prolonged application of 5 mM D-*O*-phosphoserine. However, the antagonistic surround response was blocked (see Fig. 1 legend). The surround response of bipolar cells is believed to result from horizontal cell feedback[14-19]. Therefore, the maintenance of the centre response during the loss of the surround response in the OFF bipolar is consistent with a selective blocking of the horizontal cells. In Fig. 1*c*, D-*O*-phosphoserine was applied to the retina while recording from an ON bipolar cell; as with the OFF bipolar, the drug did not reduce the centre response but the antagonistic surround response was suppressed.

To explore the pharmacology of D-*O*-phosphoserine, we compared its action with that of known excitatory amino-acid agon-

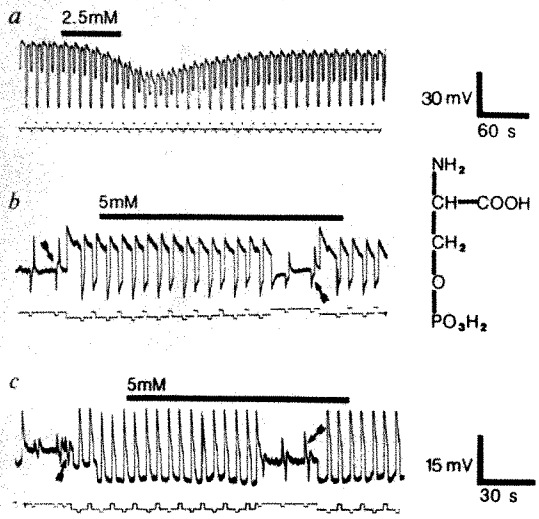

Fig. 1 Action of D-*O*-phosphoserine on the light responses of second-order neurones. *a*, 2.5 mM D-*O*-phosphoserine hyperpolarized and suppressed 50% of the synaptic responses of horizontal cells, while more prolonged application of twice this concentration did not diminish the centre responses of either OFF (*b*) or ON (*c*) bipolar cells. However, the sustained antagonistic surround response in bipolar cells, evoked by flashing an annulus during maintained small-spot illumination, was suppressed; this is shown by the reversal in polarity of the surround responses indicated by arrows before and during drug application. Bars above the traces indicate the duration of drug application; square pulses below the voltage traces mark the time of light stimuli. Upward pulses represent small spots (200 μm) and downward pulses mark annular stimulation (internal diameter 400 μm, external diameter greater than retinal diameter). Illumination, 5×10^{-9} W cm^{-2}. The lower calibration applies to *b* and *c*. The molecular formula for D-*O*-phosphoserine is shown at the right.

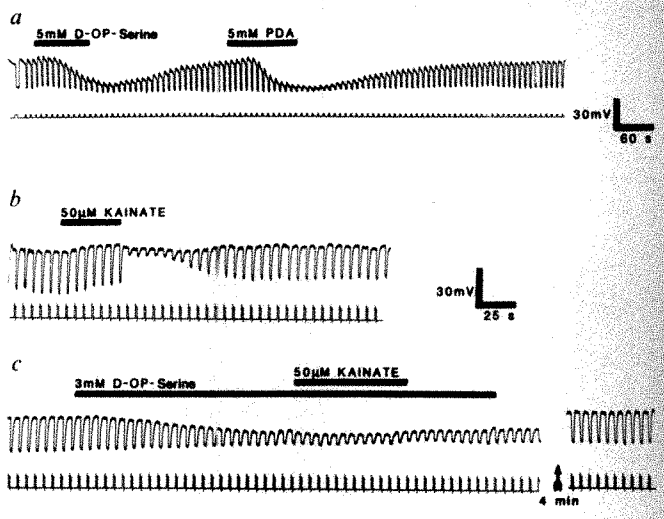

Fig. 2 *a*, Similarity of action of D-*O*-phosphoserine (D-OP-Serine) and *cis*-2,3-piperidine dicarboxylic acid (PDA; Cambridge Research Biochemicals), an excitatory amino-acid antagonist, on the light responses of a horizontal cell. The traces in *b* and *c*, from the same horizontal cell, show that D-*O*-phosphoserine suppresses the action of both kainic acid and the photoreceptor neurotransmitter. Diffuse light stimuli were used.

ists and antagonists. One antagonist that is effective on second-order neurones is *cis*-2,3-piperidine dicarboxylic acid (PDA), which blocks photoreceptor input to both OFF bipolars and horizontal cells[19]. At equivalent concentrations, D-*O*-phosphoserine and *cis*-2,3-piperidine dicarboxyclic acid had a similar effect on the synaptic responses of horizontal cells (Fig. 2*a*) although PDA was a slightly more potent antagonist.

The photoreceptor–horizontal cell synapse is mediated by a glutamate-preferring receptor and kainic acid mimics the action of the photoreceptor neurotransmitter[6]. Therefore, we evaluated the ability of D-*O*-phosphoserine to antagonize the effects of exogenously applied kainic acid. Figure 2*b* illustrates that a brief application of 50 μM kainic acid drives a horizontal cell towards the dark resting membrane potential and suppresses the light response, mimicking the endogenous transmitter. Figure 2*c* shows the same cell after recovery from the kainic acid-induced depolarization. D-*O*-phosphoserine at 3 mM produced a hyperpolarization and a reduction of the light response; in the continued presence of the drug, a more prolonged application of kainic acid had little effect on the neurone. γ-Aminobutyric acid (GABA) at 5 mM directly depolarizes mudpuppy horizontal cells to close to their dark membrane potential (M.S., unpublished observation); D-*O*-phosphoserine does not block this GABA-induced depolarization, indicating that the former is not acting by shunting horizontal cells towards an equilibrium potential below the dark membrane potential. These results suggest that D-*O*-phosphoserine suppresses the response of horizontal cells to light by blocking glutamate-like synaptic receptors.

Although it is not very potent, D-*O*-phosphoserine seems to possess a selectivity that may be useful as a pharmacological probe to identify and characterize excitatory amino-acid receptors. This ligand has also been reported to displace glutamate at some binding sites in rat forebrain[20]. The action of D-*O*-phosphoserine in the distal retina reveals a discrete glutamate receptor subtype at the horizontal cell synapse. We have reported previously that the ON bipolar cell possesses a synaptic glutamate receptor not found in other retinal neurones[9]. From these observations we conclude that there are three glutamate receptor subtypes in the outer plexiform layer and that each pharmacological subtype is found on a distinct physiological class of second-order neurone.

The reason for this receptor diversity and functional segregation is unclear; it may be related to receptor–ionophore coupling as it has been proposed that the synaptic potential of each class of second-order neurone is generated by a discrete ionic mechanism[21–23]. Another possible explanation, suggested by noise analysis in dogfish and turtle retinas, is that the kinetics of synaptic communication differs among the second-order neurones[24–26]. This may be an important coding mechanism for information transfer mediated by postsynaptic receptors. The differentiation of excitatory amino-acid receptors in the distal retina may elucidate further the role of receptors in synaptic communication.

Expression of interleukin-2 receptors as a differentiation marker on intrathymic stem cells

Rhodri Ceredig*, John W. Lowenthal*, Markus Nabholz† & H. Robson MacDonald*

* Ludwig Institute for Cancer Research, Lausanne Branch, and † Genetics Unit, Swiss Institute for Experimental Cancer Research, 1066 Epalinges, Switzerland

The thymus is regarded as the primary site for T-cell lymphopoiesis[1], but very little is known about the lineage interrelationships of cells within that organ. At least four subpopulations of mouse thymocytes can be defined on the basis of staining with monoclonal antibodies directed against the T-cell differentiation antigens Lyt-2 and L3T4 (ref. 2). Thus immunocompetent (medullary) thymocytes, like peripheral T cells, express either Lyt-2 (cytotoxic phenotype) or L3T4 (helper phenotype) but not both, whereas non-functional (cortical) thymocytes express both markers. In addition, a small subpopulation comprising 2–3% of cells in the thymus and expressing neither Lyt-2 nor L3T4 has recently been described[2]. The latter cells have the properties of intrathymic 'stem cells' in that they are the first to appear in the embryonic thymus[2,3] and at least some can be shown to give rise, both *in vivo* (ref. 4. and our unpublished data) and *in vitro*[5], to other thymocyte subpopulations. We show here that 50% of Lyt-2$^-$/L3T4$^-$ cells in the adult thymus express receptors for the polypeptide growth hormone interleukin-2 (IL-2)[6] whereas other cells in the thymus do not. Furthermore, immunohistochemical localization studies on frozen sections indicate a disperse distribution of IL-2 receptor-positive cells in both the cortex and medulla. These novel findings have potential implications in the context of current models of differentiation pathways within the thymus.

Very few positive cells (~2%) were observed when unfractionated thymocytes were exposed to anti-IL-2-receptor monoclonal antibody (PC61) and analysed by flow microfluorometry (FMF)(Fig. 1), in line with a previous report[7]. However, when the Lyt-2$^-$/L3T4$^-$ subpopulation was isolated by negative selection with a mixture of monoclonal antibodies and complement, clear staining of 51 ± 3% (mean ±s.d. of three experiments) of the cells was observed (Fig. 1). As Lyt-2$^-$/L3T4$^-$ cells account for 3% of total thymocytes[2], these data suggest (but do not

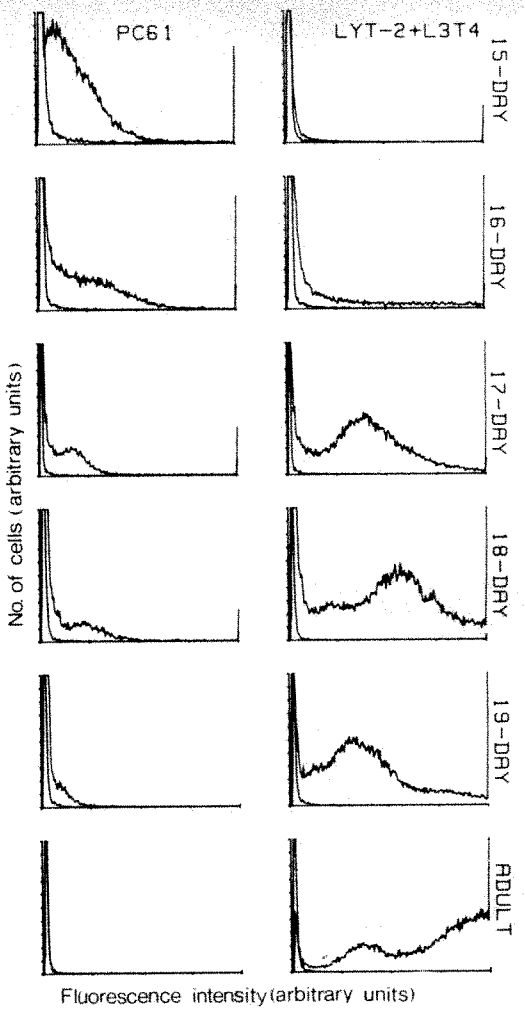

Fig. 2 Ontogeny of IL-2 receptor expression in the developing embryonic thymus. C57BL/6 Thymocytes of the indicated gestational ages, and control adult thymocytes, were stained with PC61 monoclonal antibody (left panels) and analysed by FMF as described in Fig. 1 legend. For comparison, the proportion of Lyt-2$^-$/L3T4$^-$ cells in the same population was determined by simultaneous staining with anti-Lyt-2 and anti-L3T4 monoclonal antibodies[2] (right panels). The proportions of PC61$^+$ and Lyt-2$^-$/L3T4$^-$ cells, respectively, were: day 15 (66%, 88%), day 16 (40%, 60%), day 17 (15%, 30%), day 18 (5%, 15%), day 19 (4%, 10%), adult (2%, 3%).

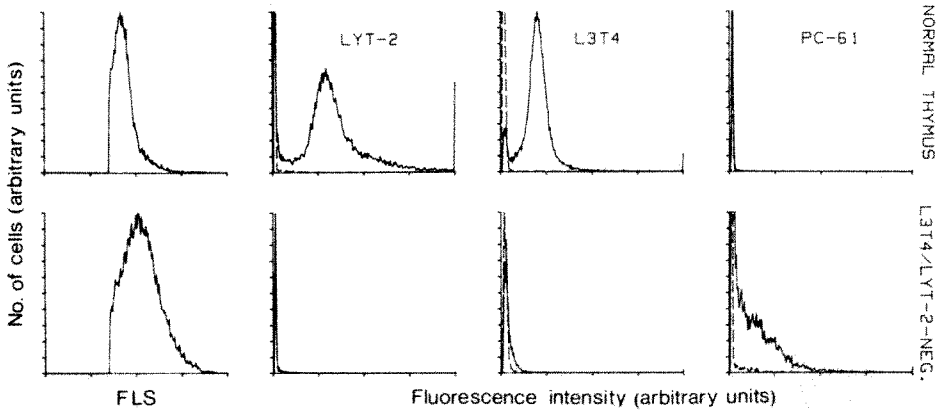

Fig. 1 Flow microfluorimetric (FMF) analysis of IL-2 receptor expression by Lyt-2$^-$/L3T4$^-$ thymocytes (lower row). Upper row, normal thymus controls. Linear fluorescence or forward light scatter (FLS) histograms are expressed in arbitrary units. Dotted lines represent staining with the fluorescent conjugate only.
Methods. C57BL/6 thymocytes (50×10^6 ml^{-1}) were incubated with a mixture of rat IgM monoclonal antibodies directed against Lyt-2 (3.168.8.1[21], provided by F.W. Fitch) and L3T4 (LICR.LAU.RL172.4) at a 1:10 final dilution of hybridoma culture supernatant. The latter monoclonal antibody was obtained by fusing spleen cells from a rat immunized with the L3T4-positive thymoma EL-4 to the non-secreting mouse myeloma X63-Ag8.653 and screening the hybrids for selective complement-dependent lysis of L3T4-positive thymomas (R.C., R. K. Lees and H. R. MacD., unpublished data). After incubation for 15 min at 37 °C, rabbit complement was added to a 1:20 final dilution for an additional 45 min. Treated cells were passed over Ficoll-Hypaque (specific gravity 1.077) and washed twice. Viability was >90%, and cell recovery was 1.0 ± 0.3% (mean ± s.d. of six experiments). For FMF analysis, aliquots of 1×10^6 control or Lyt-2$^-$/L3T4$^-$ thymocytes in 100 μl were incubated at 4 °C with appropriate (saturating) concentrations of rat monoclonal antibodies directed against either Lyt-2 (53-6.7[22], provided by J. Ledbetter), L3T4 (H129-19[23], provided by M. Pierres) or the murine IL-2 receptor (PC61). After 30 min, 50 μg of fluorescein isothiocyanate-conjugated rabbit anti-rat immunoglobulin (Nordic Laboratories) was added for an additional 30 min at 4 °C. Control samples were stained with the second step reagent alone. All samples were then passed on a flow cytometer (FACS II, Becton and Dickinson) gated to exclude nonviable cells[24].

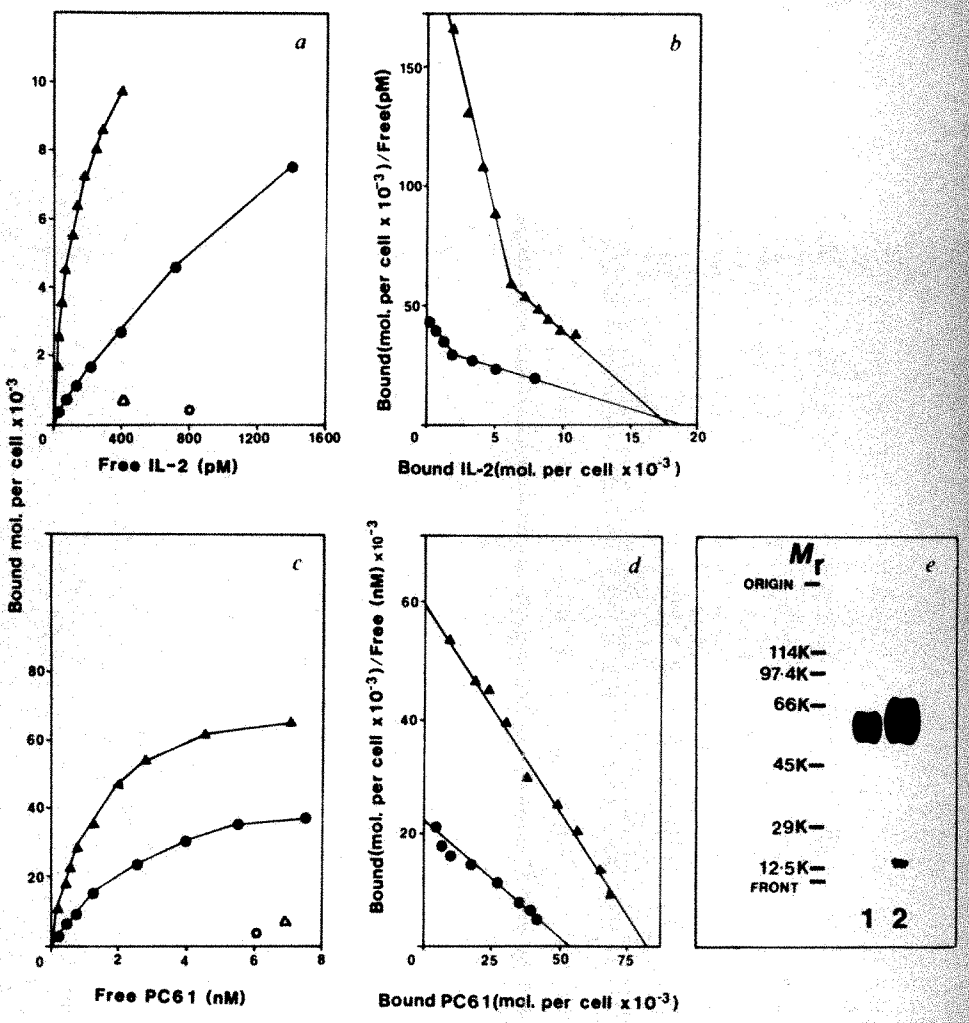

Fig. 3 Equilibrium binding and immunoprecipitation analysis of IL-2 receptors on Lyt-2$^-$/L3T4$^-$ thymocytes and Con A blasts. Lyt-2$^-$/L3T4$^-$ thymocytes (prepared as described in Fig. 1) and Con A blasts (prepared by culturing 2×10^6 C57BL/6 spleen cells for 4 days together with 1.5 μg ml^{-1} Con A and 10% (v/v) supernatant from phorbol myristate acetate-stimulated EL-4 cells) were passed over Ficoll-Hypaque and washed extensively. ^{3}H-IL-2 from biosynthetically labelled Jurkat cell supernatant was purified by immunoaffinity chromatography on a column of Aphigel coupled to DMS-3 anti-IL-2 monoclonal antibody (provided by K. A. Smith) as described in detail elsewhere[25]. ^{3}H-PC61 was purified from biosynthetically labelled hybridoma culture supernatant by dialysis followed by passage over protein A-Sepharose. For the binding assays (*a*–*d*) aliquots of 1–3 $\times10^6$ cells in 200 μl were incubated for 20 min at 4 °C with varying concentrations of ^{3}H-IL-2 or ^{3}H-PC61. Free and cell bound radioactivity was measured by liquid scintillation counting following centrifugation of samples through a paraffin/silicon oil gradient[10]. The number of bound IL-2 and PC61 molecules per cell was calculated given the specific activities of 2,500 c.p.m. ng^{-1} and 210 c.p.m. ng^{-1}, respectively. The M_r of IL-2 and PC61, as judged by SDS-PAGE, is 15,000 (15K) and 170K, respectively. Nonspecific binding was measured by incubating the cells in the presence of a 100-fold excess of the relevant unlabelled ligand. Equilibrium binding of IL-2 (▲, Con A blasts; ●, thymocytes) is shown in *a* after subtraction of non-saturable binding (open symbols). The open symbols represent ^{3}H-IL2 binding in the presence of either excess cold IL-2 or PC61 mAb. For Con A blasts, binding was saturable at a free IL-2 concentration of ~2 nM, whereas the binding to Lyt-2$^-$/L3T4$^-$ thymocytes was not saturable at this concentration. Equilibrium binding of ^{3}H-PC61 is shown in *c* (same symbols as *a*). Scatchard plots of these data are shown in *b* and *d*. The number of high- and low-affinity IL-2 binding sites was estimated by computer analysis of the two linear components of the Scatchard plots. For immunoprecipitation analysis (*e*), Lyt-2$^-$/L3T4$^-$ thymocytes (3×10^6 cells, lane 1) or Con A blasts (10×10^6 cells, lane 2) were labelled by the enzyme catalysed surface iodination technique of Hubbard and Cohn[26] modified as described previously[27]. The labelled cells were lysed in 0.5 ml of cold 1% recondensed Triton X-114 in 50 nM Tris-HCl (*p*H 7.7) containing 0.3 M NaCl and 5 mM EDTA. The aqueous and detergent phases were separated according to Bordier[28]. The lysates were pre-cleared for immunoprecipitation by sequential addition of 5 μl normal rat serum, 20 μl rabbit anti-rat immunoglobulin and 12.5 μl Protein-A-Sepharose 4B (twice). The pre-cleared lysates were then incubated for 60 min with purified PC61 antibody coupled to Sepharose 4B, followed by extensive washing in phosphate buffer (*p*H 8.2). The immunoprecipitates were analysed by SDS-PAGE according to Laemmli[29] on 7.5–15% gradient gels. Samples were reduced with 0.1 M dithiothreitol and denatured by boiling in 4% SDS. After electrophoresis, gels were autoradiographed at −70 °C on Kodak XAR film. Exposure times were 8 days (lane 1) and 4 days (lane 2). M_r standards were β-galactosidase (114K), phosphorylase *b* (97.4K), bovine serum albumin (66K), ovalbumin (45K), carbonic anhydrase (29K) and cytochrome *c* (12.5K).

prove) that all PC61$^+$ cells are contained within this subpopulation. No Lyt-2$^+$ or L3T4$^+$ cells were detected after the antibody treatment; however, ~90% of the cells expressed Thy-1. The fluorescence distribution of PC61$^+$ cells was heterogeneous, with a mean intensity corresponding to 76% of that obtained for IL-2-dependent cells from a cytotoxic T-cell line[8] (included in each experiment as a positive control). Forward light scatter (FLS) analysis of Lyt-2$^-$/L3T4$^-$ cells indicated that they were considerably larger than most thymocytes (124 ± 4 arbitrary units as compared with a value of 100 units for small cortical thymocytes). Simultaneous FLS and PC61 fluorescence analysis of the Lyt-2$^-$/L3T4$^-$ subpopulation did not reveal any size distinction between PC61$^+$ and PC61$^-$ cells.

The early (day 15) embryonic thymus, which is known from transplantation experiments to be a rich source of intrathymic stem cells[9], is also enriched for Lyt-2$^-$/L3T4$^-$ cells[2], but their proportion decreases rapidly during subsequent development[2]. When thymocytes from embryos of differing gestational ages were stained with PC61 and analysed by FMF, a good correlation was observed between the proportion of PC61$^+$ and Lyt-2$^-$/L3T4$^-$ cells (Fig. 2).

Several other independent experimental approaches were used to verify IL-2 receptor expression on Lyt-2$^-$/L3T4$^-$ thymocytes. Equilibrium binding assays using biosynthetically labelled immunoaffinity-purified IL-2 (^{3}H-IL-2) demonstrated that adult Lyt-2$^-$/L3T4$^-$ thymocytes bound IL-2, and that this binding could be competed for by excess unlabelled IL-2 or by purified PC61 antibody (Fig. 3*a*). This latter result further confirms the fact that PC61 reacts with the IL-2 receptor. Scatchard plot analysis of the IL-2 binding data (Fig. 3*b*) shows that Lyt-2$^-$/L3T4$^-$ thymocytes express two classes of receptors with differing affinity for IL-2 (apparent dissociation constant, K_D, of 96 and 8,130 pM). The total number of IL-2 binding sites per cell was about 14,700, with 1,200 receptors being of the high-

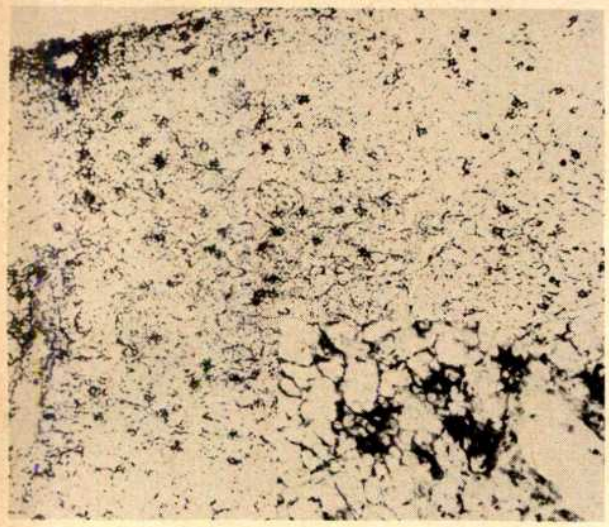

Fig. 4 *In situ* localization of PC61$^+$ cells in the thymus. Thymuses from 6-week-old C57BL/6 mice were removed and snap frozen as previously described[17]. PC61 monoclonal antibody was directly coupled to biotin and the bound antibody revealed by adding an avidin–peroxidase conjugate[30] followed by freshly prepared 3,3 diaminobenzidine solution containing 0.06% H_2O_2. At low magnification (×450), positively stained cells are seen as individual cells and small clusters scattered throughout the cortex. Insert (×890): positive cells are also seen surrounding small blood vessel (bottom right) in medulla.

affinity class. By comparison, concanavalin A (Con A)-activated T lymphocytes expressed slightly more IL-2 receptors (37,000 total and 3,000 high-affinity binding sites) and bound ^{3}H-IL-2 with higher affinity (K_D = 19 and 1,360 pM for high- and low-affinity receptors, respectively). Previous reports indicated that activated T lymphocytes expressed only a single class of high-affinity IL-2 receptors[10]; however, it has recently become clear that activated T lymphocytes express two classes of receptors when very high concentrations of ^{3}H-IL-2 are used[11].

The significance of the reduced affinity of IL-2 receptors on adult Lyt-2$^-$/L3T4$^-$ thymocytes compared with Con A blasts is not known. For antigen- or mitogen-activated mature T cells and IL-2-dependent T-cell lines, there is a good quantitative correlation between the K_D of high-affinity IL-2 receptors (~20 pM) and the IL-2 concentration required for half-maximal proliferation[6] (by definition, 1 unit ml^{-1}). In the present case, saturation of IL-2 receptors on Lyt-2$^-$/L3T4$^-$ cells would be more difficult to achieve because of their low affinity (K_D = 96 pM), and indeed we and others (see accompanying paper[12]) have thus far observed only marginal proliferation (as judged by ^{3}H-thymidine incorporation) when such cells are cultured in the presence of extremely high concentrations (100–300 units ml^{-1}) of affinity-purified or recombinant IL-2.

Equilibrium binding with biosynthetically labelled purified PC61 monoclonal antibody (^{3}H-PC61) confirmed and extended the fluorescence results. Figure 3*c* shows that ^{3}H-PC61 binding to adult Lyt-2$^-$/L3T4$^-$ thymocytes and Con A blasts is saturable and can be competed for by excess unlabelled PC61 antibody. From Scatchard plots of these data (Fig. 3*d*), the total number of PC61 binding sites is 53,000 for thymocytes and 81,000 for Con A blasts, and both cell populations bind the monoclonal antibody with similar affinity (K_D of 2.1 nM and 1.3 nM, respectively). The reason for the apparent excess of PC61 over IL-2 binding sites is not clear, but a similar discrepancy has been observed for IL-2[10] and anti-Tac[13] binding to human HUT-102 cells.

Analysis by SDS-polyacrylamide gel electrophoresis (PAGE) under reducing conditions (Fig. 3*e*) illustrates that PC61 monoclonal antibody precipitates membrane components of similar apparent relative molecular mass (M_r = 55,000–65,000) from adult Lyt-2$^-$/L3T4$^-$ thymocytes and Con A blasts. These results are similar to those reported for a variety of human and mouse T-cell lines[7,13]. In addition, bands of lower M_r (15,000–25,000) were precipitated from Con A blasts. The nature of this low-M_r material is unknown, but we find similar results with other T-cell lines and with an independently derived anti-IL-2-receptor monoclonal antibody (7D4[7], kindly provided by T. R. Malek).

The apparently unique reactivity of PC61 antibody with Lyt-2$^-$/L3T4$^-$ thymocytes provides an opportunity to determine the anatomical location of these putative stem cells *in situ*. Immunohistochemical localization of PC61$^+$ cells by the peroxidase method (Fig. 4) shows that individual cells (or small clusters) can be seen scattered more or less at random throughout both the thymic cortex and medulla. This distribution is at odds with the widely held view that thymic maturation proceeds sequentially from the subcapsular region through the cortex to the medulla[14]; however, it is consistent with early studies by Metcalf[15] as well as the recent data of Ezine *et al.*[16] and Ceredig and Schreyer[17] suggesting a focal (clonal?) distribution of donor-derived (putative stem) cells repopulating the thymus in Thy-1 congenic radiation bone marrow chimaeras. It remains to be determined whether the foci of IL-2- receptor-bearing cells observed here and as recently reported by Takacs *et al.*[31] are associated with a particular non-lymphoid component of the thymus.

The presence of IL-2 receptors on Lyt-2$^-$/L3T4$^-$ thymocytes raises interesting questions relevant to T-cell differentiation and activation. Among mature T cells, IL-2 receptor expression is always linked to an activation process dependent on antigen[18] or mitogen[19] binding. In this context, the apparently 'spontaneous' expression of IL-2 receptors on a subpopulation of intrathymic stem cells raises the possibility that receptor expression during the early stages of T-cell differentiation is not yet linked to specific antigenic stimulation. Alternatively, IL-2 receptor expression by these cells may reflect some transient 'antigen-like' differentiative stimulus (either cellular or humoral) intrinsic to the thymus. If the latter hypothesis is correct, the data presented here provide evidence that the T-cell specificity repertoire may result from *in situ* selection (either positive or negative) by self antigens within the thymus[20].

We thank Drs K. Smith, F. Fitch, J. Ledbetter and M. Pierres for their generous gifts of monoclonal antibodies, also R. Lees and F. Besençon for technical assistance, M. Schreyer for help with the immunohistochemistry, and P. Zaech for operating the FACS II. This work was supported in part by a grant from the Swiss NSF (to M.N.).

Expression and function of interleukin-2 receptors on immature thymocytes

David H. Raulet

Center for Cancer Research and Department of Biology, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139, USA

T-cell differentiation represents a unique system for studying mechanisms of lymphoid development because it occurs in a segregated site, the thymus, in which distinct subpopulations of thymocytes at various stages of differentiation can be defined on the basis of the differential expression of T-cell surface antigens as well as topography. There is particular interest in thymocyte differentiation because the genotype of radioresistant thymus cells influences the specificity repertoire of the pool of T cells that mature therein: that is, the major histocompatibility complex (MHC) antigens expressed by thymus cells bias the pool of maturing T cells towards recognition of antigens in the 'context' of the products of that MHC haplotype ('thymus education'; refs 1–3). Immature T cells with affinity for thymus MHC antigens are generally thought to undergo a stage of positive selection in the thymus[4–6]. Here we report that 30% of cells in the least mature adult thymocyte subpopulation yet defined, as well as 50% of immature fetal thymocytes, express receptors for interleukin-2 (IL-2, the T-cell growth factor) without *in vitro* induction, and will proliferate vigorously in an IL-2-dependent fashion if provided with co-stimulating mitogen.

Recent studies with monoclonal antibodies reactive with the T-cell antigens Lyt-2, L3T4 and Thy-1 have defined at least four subpopulations of thymocytes in the adult thymus. Thymocytes with the mature phenotypes L3T4$^+$, Lyt-2$^-$, Thy-1$^+$ (helper T-cell phenotype) or L3T4$^-$, Lyt-2$^+$, Thy-1$^+$ (cytolytic T-cell phenotype) appear late in fetal ontogeny[7,8] and most are functional in *in vitro* assays of T-cell activities[7,9,10]. These cells may include end-stage thymocytes awaiting export from the thymus although medullary thymocytes with these phenotypes may not be exported[11]. A large subpopulation (~85%) of thymocytes are mostly small noncycling cells with the phenotype L3T4$^+$, Lyt-2$^+$, Thy-1$^+$, a phenotype not yet found amongst peripheral T cells; the specific ontogenetic relationship of these cells to other thymocyte subpopulations (that is, whether they are intermediates) is presently obscure. A fourth thymus subpopulation (~3% of adult thymocytes) has the phenotype L3T4$^-$, Lyt-2$^-$, Thy-1$^+$ and includes mostly blast cells, many of which are cycling[12]. In addition to the immature phenotype of these cells, there is evidence that they represent the least mature thymocyte subpopulation yet defined: on transfer to irradiated recipients these cells, unlike other thymocytes, are able to repopulate the recipient thymus and give rise with time to each of the other thymocyte subpopulations[12]. Furthermore, before day 17 of embryonic murine development most (80–95%) thymocytes have the L3T4$^-$, Lyt-2$^-$, Thy-1$^+$ phenotype[7,8].

In our studies of the expression of IL-2 receptors by thymocytes, we used the recently described rat monoclonal antibodies 3C7 (IgG) and 7D4 (IgM) isolated by Malek and Shevach[13,14]. These antibodies recognize different epitopes on the IL-2 receptor as they do not compete with each other for binding, and the binding of 3C7 (but not 7D4) is blocked by purified IL-2: both antibodies block IL-2-dependent proliferation and precipitate a similar polypeptide of relative molecular mass 50,000–60,000 (refs 13, 14).

Indirect immunofluorescent staining profiles of day 16 fetal thymocytes and adult lymph node cells with various monoclonal antibodies (Fig. 1) show that most fetal thymocytes (95%) are Lyt-2$^-$, Thy-1$^+$, whereas adult thymocytes are predominantly Lyt-2$^+$, Thy-1$^+$ cells. About 50% of fetal thymocytes bind the 3C7 anti-IL-2 receptor antibody and 30% bind the 7D4 antibody.

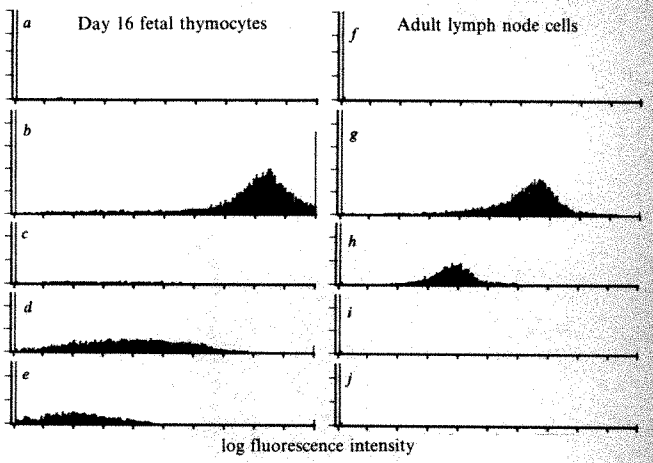

Fig. 1 Fetal thymocytes express IL-2 receptors. BALB/cAnN fetal thymocytes (*a–e*) from day 16 of gestation (day 0 is the day of observation of vaginal plugs) or adult (8 weeks old) lymph node cells (*f–j*) were stained indirectly with the following rat monoclonal antibodies: *a, f*, no antibody; *b, g*, anti-Thy-1 (T24, a rat/mouse hybridoma secreting IgG anti-Thy-1, provided by Dr Ian Trowbridge); *c, h*, anti-Lyt-2 (53-6.7)[17]; *d, i*, anti-IL-2 receptor (3C7)[14]; *e, j*, anti-IL-2 receptor (7D4)[13,14].
Methods. Cell suspensions (1×10^6 cells in 50 μl) were incubated in phosphate-buffered saline (PBS) containing 5% fetal calf serum (FCS), 0.1% NaN_3 for 30 min at 4 °C with or without monoclonal antibodies, washed three times, and resuspended in 50 μl of the same medium containing 25 μg ml^{-1} affinity-purified, mouse serum absorbed fluorescent goat anti-mouse IgG antibodies (Kirkegaard and Perry, Gaithersburg, Maryland). Following incubation for 30 min at 4 °C, the cells were washed three times, resuspended in 0.5 ml of the PBS–FCS–NaN_3 solution and analysed by flow microfluorimetry with an Ortho Cytofluorograf System 50 interfaced with an Ortho 2150 computer. The antibodies were used at the following excess concentrations as determined in pilot experiments: T24, 1/10 dilution of culture supernatant; 53-6.7, 1/5 dilution of 10-fold concentrated culture supernatant; 3C7 and 7D4, 1/50 dilution of ascites fluid.

(The smaller proportion of cells positive with 7D4 antibodies and the weaker staining intensity of these cells probably results from the inferior binding of our secondary fluorescent goat-anti-rat IgG reagent to IgM molecules; data not shown.) In contrast, expression of IL-2 receptors by adult lymph node cells is nearly undetectable (as in unstimulated splenic T cells[14]), reflecting the need for antigenic or mitogenic stimulation for expression of IL-2 receptors by mature T cells.

To assess expression of IL-2 receptors by immature thymocytes in the adult thymus, we purified L3T4$^-$, Lyt-2$^-$ thymocytes by two rounds of lysis of whole thymocyte populations with monoclonal anti-L3T4 (GK 1.5[15]) and anti-Lyt-2 (AD4(15)[16]) antibodies plus complement and stained them indirectly with monoclonal antibodies. Flow cytometric analysis of these cells, with unfractionated thymocytes for comparison (Fig. 2), indicates that cells prepared in this way are routinely ~95% Lyt-2$^-$, L3T4$^-$, Thy-1$^+$ cells. By forward-angle scatter measurements, L3T4$^-$, Lyt-2$^-$ thymocytes are larger than most unfractionated thymocytes (refs 7, 12 and our unpublished data) and express Thy-1 at high levels. The background staining of these cells in the negative control results from a small number of cells (about 3–5%) binding small amounts of anti-L3T4 or anti-Lyt-2 and which presumably escaped complement lysis. As can be seen, about 30% of L3T4$^-$, Lyt-2$^-$ thymocytes stain with the 3C7 and 7D4 antibodies reactive with the IL-2 receptor. In contrast, very few unfractionated thymocytes stain with these reagents[14] (Fig. 1). However, a few positive cells, with forward-angle scatter characteristics consistent with the size of L3T4$^-$, Lyt-2$^-$ thymocytes, can be seen in plots of forward-angle scatter versus fluorescence (not shown). In three experiments the proportion of positive cells in unfractionated thymocyte populations

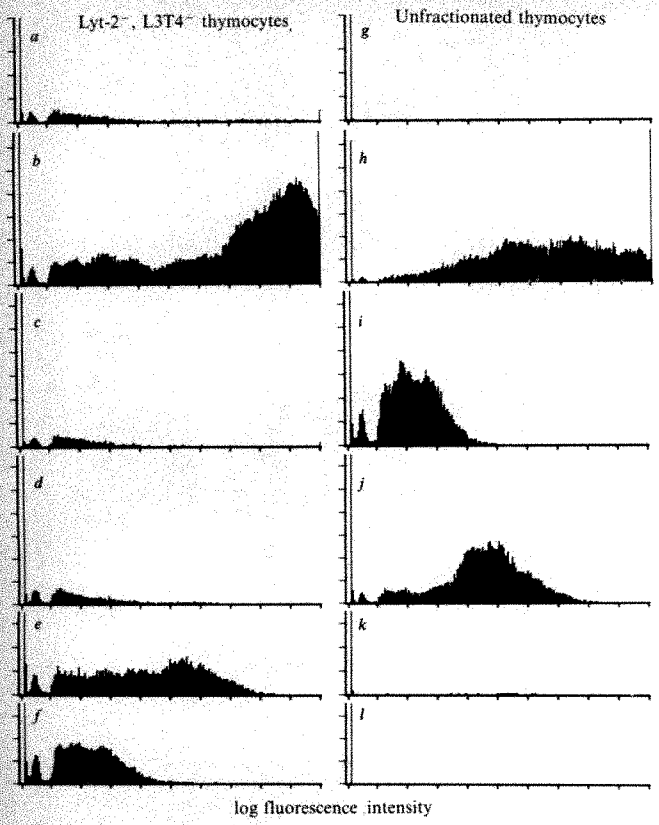

Fig. 2 Immature thymocytes in the young adult thymus express IL-2 receptors. Lyt-2$^-$, L3T4$^-$ thymocytes (*a–f*) or unfractionated thymocytes (*g–l*) from 4-week-old BALB/cAnN mice were stained indirectly as described in Fig. 1 legend with the following rat monoclonal antibodies: *a*, *g*, no antibody; *b*, *h*, anti-Thy-1 (T24); *c*, *i*, anti-L3T4 (1/20 dilution of 10-fold concentrated culture supernatant from the GK 1.5 hybridoma); *d*, *j*, anti-Lyt-2 (53-6.7); *e*, *k*, anti-IL-2 receptor (3C7); *f*, *l*, anti-IL-2 receptor (7D4). Concentrations of antibodies as in Fig. 1.

Methods. Lyt-2$^-$, L3T4$^-$ thymocytes were isolated from thymocyte suspensions by two consecutive treatments with ascites fluids (1/100 dilution) of anti-Lyt-2.2 (AD4(15))[16] and anti-L3T4 (GK 1.5) plus complement (C). Cells at a concentration of 1×10^7 ml^{-1} in RPMI-1640 medium, 5% FCS, were incubated with antibodies at 4 °C for 30 min, washed once and resuspended in a mixture of guinea pig complement (Gibco) at a 1/10 dilution and selected rabbit complement at a 1/50 dilution. Following incubation for 45 min at 37 °C, the surviving cells (about 2% of the starting number) were purified on step gradients of Ficoll–Isopaque[18], washed, and the entire procedure was repeated except that anti-I-A^d (1/100 dilution of ascites fluid of BP107)[19] was included in the antibody cocktail in order to deplete any B cells or macrophages in the cell preparation. The overall yield of cells from the treatments was ~1% in several experiments.

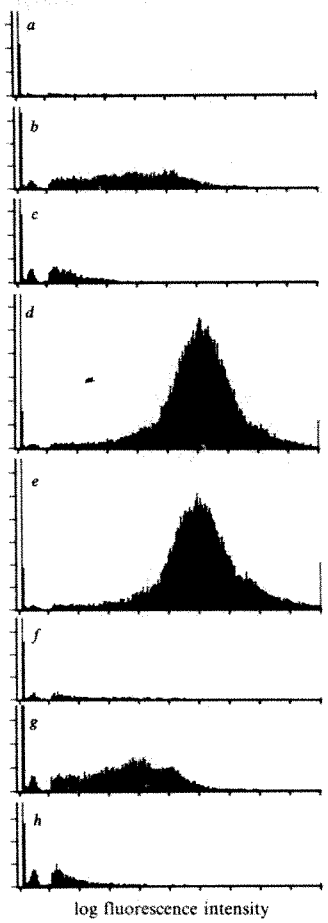

Fig. 3 IL-2 blocks binding of anti-IL-2 receptor antibodies to immature thymocytes. 1×10^6 day 16 fetal thymocytes (*a–e*) or young adult Lyt-2$^-$, L3T4$^-$ thymocytes (*f–h*) isolated as described in the legends to Figs 1 and 2, were preincubated for 30 min at room temperature with (*c*, *e*, *h*) or without (*a*, *b*, *d*, *f*, *g*) 1 μg purified, bacterially derived recombinant human IL-2 (AmGen Biologicals) in 50 μl of PBS–FCS–NaN_3. Rat monoclonal antibodies were then added directly to the wells for indirect immunofluorescent staining as described in Fig. 1 legend. *a*, *f*, No antibody; *b*, *c*, *g*, *h*, a limiting (1/200) dilution of ascites fluid of the 3C7 anti-IL-2 receptor monoclonal antibody; *d*, *e*, a limiting (1/50) dilution of culture supernatant of anti-Thy-1 (T24) hybridoma.

averages ~1.0%. As L3T4$^-$, Lyt-2$^-$ thymocytes represent 3% of adult thymocytes and ~30% of these cells stain with anti-IL-2 receptor monoclonal antibody, it appears that a large fraction (or perhaps all) of IL-2 receptor-positive thymocytes are in the L3T4$^-$, Lyt-2$^-$ subpopulation.

As immature thymocytes are bound by two different monoclonal antibodies reactive with different epitopes on the IL-2 receptor, we predicted that these cells expressed IL-2 receptors or closely related structures. To establish whether the putative receptors bind IL-2, we exploited the observation that binding of the 3C7 monoclonal antibody to the IL-2 receptor can be blocked with purified IL-2[14]. Day 16 fetal thymocytes were stained indirectly with a limiting amount (as determined in a previous experiment) of 3C7 or anti-Thy-1 monoclonal antibodies in the presence or absence of 1 μg purified recombinant human IL-2. As shown in Fig. 3*a–e*, the binding of 3C7 monoclonal antibody but not anti-Thy-1 to fetal thymocytes is profoundly inhibited by the purified IL-2. Virtually identical results were obtained in a similar analysis of L3T4$^-$, Lyt-2$^-$ thymocytes isolated from young adult thymuses (Fig. 3*f–h*). The data, taken together, show that immature thymocytes express IL-2-binding receptors that express epitopes similar to their counterparts on activated mature peripheral T cells.

We next determined the density of IL-2 receptors on these immature thymocytes relative to concanavalin A (Con A)-activated peripheral T cells. We used the 7D4 monoclonal antibody as its binding is not inhibited by IL-2[14]. The antibody was used at a previously determined excess concentration. The relative level of staining of L3T4$^-$, Lyt-2$^-$ young adult thymocytes (a mean of 41 arbitrary fluorescence units on a linear scale) corresponded closely to the level of staining of Con A blasts (50 fluorescence units). Because in several experiments the level of IL-2 receptors on day 16 fetal thymocytes was virtually indistinguishable from the levels on L3T4$^-$, Lyt-2$^-$ young adult thymocytes, the fetal thymocytes also seem to express levels of receptor comparable with Con A blasts. These results indicate that IL-2 receptor expression by these immature thymocytes is at a level consistent with physiological function.

In further experiments we sought to demonstrate IL-2-dependent proliferation of adult or fetal Lyt-2$^-$, L3T4$^-$ thymocytes (Table 1). Given that immature thymocytes express high con-

centrations of IL-2 receptors, we were surprised to find that the cells responded only weakly to purified recombinant IL-2. Interestingly, a vigorous proliferative response of immature thymocytes to IL-2 was revealed by co-stimulation with the T-cell mitogen Con A, whereas the cells responded only weakly to Con A alone; this was true of both adult and fetal L3T4$^-$, Lyt-2$^-$ thymocytes. However, in two experiments the response of the fetal thymocytes to IL-2 titrated more steeply than that of the young adult L3T4$^-$, Lyt-2$^-$ thymocytes. Whether this reflects differences in receptor affinity or some other difference in these cell populations is unknown. We note that inclusion of irradiated T-cell-depleted syngeneic splenic accessory cells did not augment the response to Con A plus IL-2, nor did the accessory cells substitute for either Con A or IL-2 in stimulating the proliferative response (data not shown).

The expression of apparently functional IL-2 receptors by immature thymocytes suggests that IL-2 plays a role in thymus cell ontogeny. Of obvious interest in this context is the ontogeny of IL-2-producing cells in the thymus. IL-2-producing thymocytes are not detected before day 19 of fetal ontogeny and seem to correlate with the L3T4$^+$, Lyt-2$^-$ subpopulation[7], but it is not clear whether the methods of that study used appropriate conditions to detect IL-2 production by immature thymocytes. We are now assessing other protocols for stimulating IL-2 production by immature thymocytes.

A possible role of IL-2 in the positive selection of thymocytes is suggested by the requirement of Con A for potent proliferative responses to IL-2 despite the fact that the cells express IL-2 receptors without *in vitro* induction. In the case of mature resting T cells, which do not constitutively express IL-2 receptors, mitogenic or antigenic stimulation leads to expression of IL-2 receptors and subsequent IL-2-dependent proliferation. Although expression of IL-2 receptors above a threshold level may be a sufficient condition for IL-2-dependent proliferation of mature T cells, our data suggest that additional requirements, provided by mitogenic stimulation, are operative, at least in the case of immature thymocytes. Con A may act by stimulating cell surface structures on immature thymocytes involved in recognition of MHC antigens and/or nominal antigens. *In vivo*, stimulation of the receptor might aid positive selection of thymocytes during the 'education' of thymocytes.

Finally, the present results do not imply that all thymocyte proliferation is IL-2 dependent, as thymic blasts with phenotypes distinct from the L3T4$^-$, Lyt-2$^-$ subpopulation have been reported[7,11].

We thank Kathryn Wright for technical assistance, Juanita Torres and the MIT Cell Sorter Laboratory for performing the flow cytometry, Drs T. Malek and E. Shevach for anti-IL-2 receptor antibodies, and Drs D. Dialynas and F. Fitch for the GK 1.5 hybridoma. This work was supported by grant CA-28900 and by a grant from the Whitaker Health Sciences Fund, Massachusetts Institute of Technology.

Table 1 Proliferative responses of Lyt-2$^-$, L3T4$^-$ thymocytes

Stimulant in culture	Lyt-2$^-$, L3T4$^-$ thymocytes	
	Adult	Day 16 fetal
None	91 ± 17	52 ± 4
IL-2*, 5 U ml^{-1}	4,518 ± 701	1,220 ± 201
IL-2, 1 U ml^{-1}	2,477 ± 84	294 ± 61
IL-2, 0.2 U ml^{-1}	1,131 ± 96	246 ± 187
Con A†	253 ± 26	924 ± 85.7
Con A + IL-2, 5 U ml^{-1}	28,282 ± 1,128	18,020 ± 1,610
Con A + IL-2, 1 U ml^{-1}	18,855 ± 1,114	1,464 ± 401
Con A + IL-2, 0.2 U ml^{-1}	6,073 ± 634	215 ± 45

Thymocytes were treated once (fetal thymocytes) or twice consecutively (young adult thymocytes) with anti-Lyt-2 and anti-L3T4 monoclonal antibodies plus complement (see Fig. 2) and viable cells purified on gradients of Ficoll-Isopaque. Recoveries from complement lysis were 1.3% and 68% for the young adult and fetal cells respectively. In tests of stimulant activity, triplicate cultures of cells in round-bottom microtitre wells (Costar 3799 plates) contained 1×10^5 cells in 0.2 ml RPMI 1640 medium, 5% fetal calf serum, 50 μM 2-mercaptoethanol, 0.02% glutamine, antibiotics and the additions indicated. After culture for 48 h at 37 °C in a humidified atmosphere of 5% CO_2 in air, 0.5 μCi ^{3}H-thymidine (6.7 Ci mmol^{-1}) was added to each well and the cultures continued for 4 h, at which time the cells were collected and lysed on glass fibre filters and counted by liquid scintillation spectrometry.

* Purified human recombinant IL-2 (AmGen Biologicals) was titred in our laboratory and compared with a standard sample of IL-2 provided by Dr Richard Robb (Dupont, Nemours and Co.) which is referenced against the unit defined by Gillis and Smith[20]. The specific activity of IL-2 we calculate to be 2×10^5 U per mg protein.

† Con A (Pharmacia) was added to a final concentration of 2 μg ml^{-1}.

Developmental regulation of T-cell receptor gene expression

David H. Raulet, Richard D. Garman, Haruo Saito & Susumu Tonegawa

Center for Cancer Research and Department of Biology, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139, USA

In contrast to B cells or their antibody products, T lymphocytes have a dual specificity, for both the eliciting foreign antigen and for polymorphic determinants on cell surface glycoproteins encoded in the major histocompatibility complex (MHC restriction)[1-4]. The recent identification of T-cell receptor glycoproteins[5-7] as well as the genes encoding T-cell receptor subunits will help to elucidate whether MHC proteins and foreign antigens are recognized by two T-cell receptors or by a single receptor. An important feature of MHC restriction is that it appears to be largely acquired by a differentiating T-cell population under the influence of MHC antigens expressed in the thymus[8-10], suggesting that precursor T cells are selected on the basis of their reactivity with MHC determinants expressed in the host thymus[9-11]. To understand this process of 'thymus education', knowledge of the developmental regulation of T-cell receptor gene expression is necessary. Here we report that whereas messenger RNAs encoding the β-and γ-subunits are relatively abundant in immature thymocytes, α mRNA levels are very low. Interestingly, whereas α mRNA levels increase during further development and β mRNA levels stay roughly constant, γ mRNA falls to very low levels in mature T cells, suggesting a role for the γ gene in T-cell differentiation.

cDNA clones encoding the α- and β-subunits of the T-cell receptor have been isolated[12-17] and identified by comparison with partial protein sequences[18-20]. As reported elsewhere, the predicted primary structures of the β- and α-subunits and, in the case of the β-subunit, the genomic organization of the corresponding genetic elements show striking similarities to their

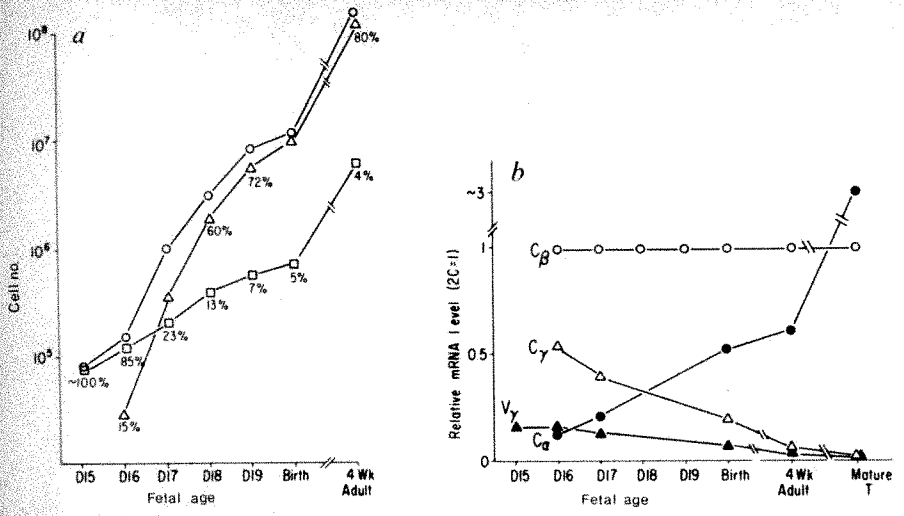

Fig. 1 *a*, Contribution of different subpopulations to thymocyte differentiation. Circles represent the approximate total cellularity of the thymus at different stages; triangles and squares represent the approximate contribution, at each stage, of 'double-positive' and 'double-negative' thymocytes, respectively. The numbers beneath the symbols represent percentages of the total. Data from Ceredig *et al.*[27]. *b*, Approximate relative levels of α, β and γ mRNAs in thymocytes and T cells as a function of fetal and adult age. Data are from the present study. The levels are relative to RNA from the 2C line, and are determined primarily from the Northern data (Figs 3, 4) with reference to the ribonuclease assay data (Fig. 2).

immunoglobulin counterparts[12-17,21-24]. A third gene, γ, has striking similarities to α and β, and may encode an additional T-cell receptor subunit[15,25,26].

Figure 1 represents our depiction of the results of Ceredig *et al.*[27] on the representation of different thymocyte subpopulations during murine development. Thymocytes with the Lyt-2$^-$, L3T4$^-$, Thy-1$^+$ cell surface phenotype (hereafter referred to as 'double-negative' thymocytes) represent the large majority of thymocytes before day 17 of fetal development, and decrease in proportional representation during development until, in the young adult (4-week-old) thymus, they represent only ~4% of the total. After day 16 of fetal development, most thymocytes express the Lyt-2$^+$, L3T4$^+$ ('double-positive') phenotype. Thymocytes with the phenotypes characteristic of mature T cells (Lyt-2$^+$, L3T4$^-$ and Lyt-2$^-$, L3T4$^+$) are detectable shortly after this time and increase in numbers during development to represent ~15% of young adult thymocytes.

The exact lineage interrelations of these subpopulations and the identity of the direct precursor of mature peripheral T cells remain controversial issues, but recent evidence shows that double-negative thymocytes are precursors of the other thymocyte subpopulations[28], and presumably of peripheral T cells. In the analyses reported here, we examine RNA from thymocytes of embryos of days 15, 16, 17 and 20 (newborn) of fetal development, and of 4-week old mice. We also examine RNA from purified double-negative thymocytes from 4-week-old mice and mature lymph-node T-cell RNAs.

T-cell receptor mRNAs were detected by Northern blot analysis and with a recently developed ribonuclease protection assay. We used RNA from the cloned alloreactive cytotoxic T-lymphocyte (CTL) line 2C (ref. 29; see also refs 15, 16) as a standard in each experiment. Titrations of 2C RNA were included so that the relative amounts of each mRNA could be estimated. As a basis for comparison, the frequencies of β and γ cDNA clones in an unselected 2C cDNA library were estimated at 0.1% and 0.02% respectively (H.S., unpublished). The library has not been screened with an α probe, but the frequency of α clones in a subtracted 2C cDNA library is one-half that of β clones[14].

The β probe corresponded to the last third of the β constant region and the 3′-untranslated region of the 3′-most of the two C_β genes ($C_{\beta'}$) (Fig. 2*a*; refs 15, 30, 31); as these are the regions of least homology between the two genes (69%), our assays probably selectively detect transcripts of the $C_{\beta'}$ gene. Analysis of β-chain RNA in developing thymocytes, using the ribonuclease protection assay, showed that β-chain constant-region transcripts are already abundant at day 15 of fetal development (Fig. 2*a*), corresponding to about three times the level found in the reference 2C CTL line. The level of C_β-RNA increases somewhat on day 17 of fetal development and remains approximately constant throughout further thymocyte development. Northern blot analysis showed that approximately two-thirds of the β transcripts in RNA from day 16 fetal thymocytes are 1.0 kilobases (kb) long, and about one-third of the transcripts are 1.3 kb long (Fig. 3*a*). Studies in the mouse[24] and human[32,33] systems suggest that the functional *V-D-J-C* transcripts of β are 1.3 kb long whereas the 1.0-kb mRNA corresponds to transcripts from incompletely rearranged loci. We estimate the level of 1.3-kb β mRNA in day 16 fetal thymocytes to be about equal to the level in RNA from the 2C cell line. The level of 1.3-kb β mRNA is roughly constant throughout further thymocyte development, and is similar in peripheral resting T cells, in T cells activated for 2 days with concanavalin A (Con A) (Figs 2*a*, 4*b*), and in the immature double-negative thymocytes from 4-week-old adult mice (Figs 2*a*, 4*b*). The fact that our β probe preferentially detects $C_{\beta'}$ mRNA may explain why we fail to observe higher levels of β mRNA in thymocytes than in mature T cells, as has been reported by others[12,24]; recent studies suggest that 97% of β transcripts in murine thymocytes use C_β, although $C_{\beta'}$ is used in most functional T cells thus far examined[30].

Genomic analysis suggests that there is only a single C_α gene (A. Hayday, G. Tanigawa, D. Diamond, H.S. and S.T., unpublished). α mRNA is barely detectable at day 16 of development and increases in level thereafter, although even in adult thymocytes it is lower than in 2C cells (Figs 2*b*, 3*b*). The late appearance of α mRNA may explain recent data suggesting that before day 17 of fetal development, thymocytes do not express the α/β heterodimer on the cell surface[34]. The level of α mRNA in resting or activated mature T cells is approximately three times that in 2C cells. The level of α mRNA in immature double-negative adult thymocytes is ~2–3-fold lower than that in 2C cells, or 6–9-fold lower than in mature peripheral T cells (Figs 2*b*, 4*a*).

Sequences coresponding to the constant region of the γ gene (C_γ) are relatively abundant in day 16 fetal thymocytes (approximately half the level in 2C by Northern analysis) and decrease in level thereafter (Figs 2*c*, 3*c*). C_γ mRNA is nearly 10-fold less abundant in young adult thymocytes than in 2C cells. The level of C_γ mRNA in adult double-negative thymocytes is the highest of any cells we have examined, corresponding to about twice the level in 2C RNA (Figs 2*c*, 4*c*). In striking contrast, the level of C_γ mRNA in mature T cells is extremely low (Figs 2*c*, 4*c*). A longer exposure of the gel shown in Fig. 2*c* was required to reveal a weak band corresponding to C_γ mRNA in mature T cells (not shown); we estimate the level of C_γ mRNA in these T cells to be more than 20-fold lower than that in 2C cells. The level of C_γ mRNA in T cells activated for 2 days with Con A is also very low (Figs 2*c*, 4*c*). C_γ mRNA levels were also very low in BALB.B lymph node T cells (not shown).

In contrast to the α and β constant-region gene segments, which appear to use a larger number of different variable-region gene segments, a single γ-chain variable-region gene segment is transcribed in each CTL clone thus far examined[15,21]. Therefore, we have been able to analyse the regulation of V_γ mRNA expression in developing thymocytes. V_γ-containing mRNA was detected in day 15 fetal thymocyte RNA using the ribonuclease

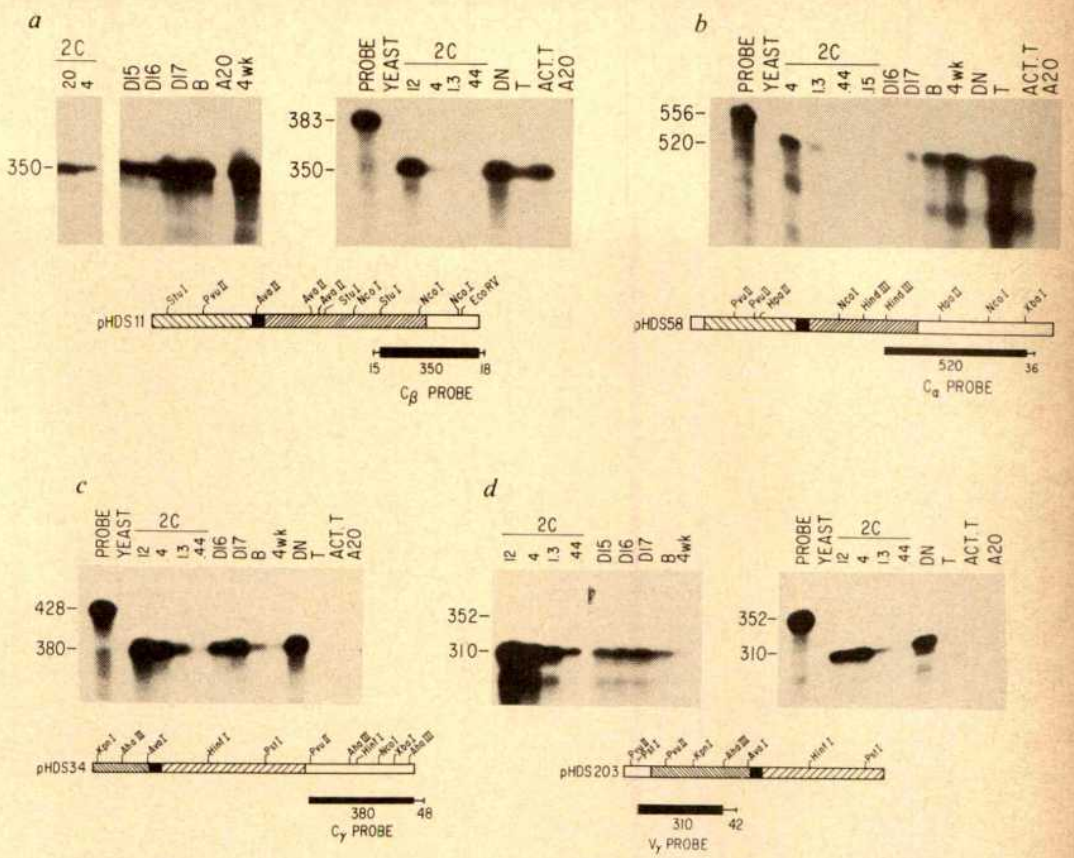

Fig. 2 Analysis of β (*a*), α (*b*), C_γ (*c*) and V_γ (*d*) mRNA levels in BALB/c AnN thymocyte and T-cell RNAs, using the ribonuclease protection assay[40]. 4 μg of total cellular RNA, or the indicated amounts of a standard preparation of total cellular RNA from the 2C cell line, were analysed. Samples containing <4 μg of 2C RNA were supplemented with yeast RNA. D15, D16 and D17 refer to RNAs prepared from thymocyte suspensions of fetuses killed 15, 16 or 17 days after detection of the vaginal plug (day 0). B, Newborn thymocytes (day 20 after detection of the vaginal plug); 4 wk, thymoctes from 4-week old mice; T, RNA from nylon-wool column-purified lymph-node T cells from 8-week-old mice, and ACT.T, RNA from the same cells activated for 42 h with Con A in the presence of equal numbers of irradiated splenic accessory cells; DN, RNA from 'double-negative' thymocytes purified from thymocyte suspensions from 4-week-old mice by two rounds of lysis with anti-L3T4 (GK1.5; ref. 41) and anti-Lyt-2 (AD4(15); ref. 42) monoclonal antibodies plus complement, and Ficoll–Isopaque purification of viable cells. Such cells are estimated to >90% pure double-negative thymocytes by cell sorter analysis (not shown). A20, RNA from the A20 B-lymphoma cell line. A20 RNA and yeast soluble RNA (4 μg) served as negative controls.

Methods. The probes were derived by subcloning in reverse orientation the indicated restriction fragment from pHDS 11 (β; ref. 15), pHDS 58 (α; ref. 17), pHDS 203 (V_γ; ref. 15) and pHDS 34 (C_γ) downstream from the SP6 promoter in the SP6 plasmids[40]. (pHDS 34 is a cDNA clone containing the 3′ portion of the γ gene; ref. 25.) ^{32}P-labelled single-stranded (SS) RNA probes complementary to T-cell receptor mRNAs were transcribed *in vitro* from the linearized SP6 plasmids, using the SP6 polymerase, in the presence of 10 μM ^{32}P-UTP (600 Ci mmol^{-1}) and excess cold ATP, GTP and CTP[40]. The lengths of the probes derived from the β, α and γ cDNAs are indicated in the diagrams (blacked in), as well as the length of the SP6 plasmid sequences also included in the transcripts (flanking lines). The ^{32}P-labelled probes were gel-purified and hybridized for 12 h at 40 °C with total cellular RNA, isolated by the guanidinium isothiocyanate/CsCl technique[43] from different cell types. The hybridization mixture was then treated with ribonuclease at 22 °C to digest single-stranded RNA. The ribonuclease was destroyed by incubation with proteinase K followed by phenol–chloroform extraction, and the RNA was ethanol-precipitated. The samples were electrophoresed on denaturing 7M urea/6% polyacrylamide gels, and the gels were subjected to autoradiography. Undigested probe was run on each gel; digestion of the SP6 plasmid-derived sequences from the probe in the experimental samples confirms the specificity of the assay.

protection assay, at ~10–15% the level found in clone 2C RNA (Fig. 2*d*). As the level of 1.5-kb C_γ mRNA in fetal thymocyte RNA is ~50% the level in 2C cells (see above), fetal thymocytes apparently contain 1.5-kb transcripts with C_γ sequences that do not hybridize with our V_γ probe. These transcripts may represent so-called 'sterile transcripts' of the γ gene, although sterile transcripts are usually shorter than their complete counterparts[24,32,33]. Alternatively, high-level transcription of C_γ rearranged to a distinct V_γ gene segment which does not hybridize with our V_γ probe would also account for the observed discrepancy.

V_γ mRNA declines to very low levels in adult thymocytes. Northern blot analysis confirmed that V_γ mRNA levels are low early in development compared with 2C and fall further after day 17 of fetal development (Fig. 3*d*). However, the level of V_γ mRNA in the adult double-negative thymocytes is much higher (approximately sevenfold) than that in fetal thymocytes (Fig. 2*d*). As is the case for C_γ-containing mRNAs, the level of V_γ mRNA in mature resting or activated T cells is extremely low, requiring for detection a longer exposure of the gel shown in Fig. 2*d*.

As the γ locus appears to undergo similar gene rearrangements on most rearranged chromosomes[15,25], Southern blot analysis of DNA from a T-cell population allows one to make a positive assessment of the extent of gene rearrangement. Rearrangement of C_γ gene segments is already detectable in DNA from fetal thymocytes at day 15, as evidenced by the appearance of a faint band of high relative molecular mass, and the diminution in intensity of the 13.4-kb germline band (Fig. 4*d*). The frequency of rearranged alleles increases during development, but ~50% of the alleles are still unrearranged even in adult thymocytes[25] (Fig. 4*d*). Our data suggest that the level of V_γ mRNA per rearranged γ allele prior to day 17 of fetal development is roughly comparable to the level in the 2C CTL line.

Approximately 50% of the γ alleles have undergone rearrangement in double-negative adult thymocytes, paralleling the increase in V_γ mRNA in these cells compared with fetal thymocytes (which also express the double-negative phenotype). These results suggest that the double-negative subpopulation has undergone maturation between the fetal and young adult stages with respect to rearrangement and expression of the γ genes. In contrast, mature T cells have a large proportion (~70%) of rearranged γ alleles[21] (Fig. 4*d*), yet have very low levels of γ mRNA.

Figure 1*b* shows the levels of α, β and γ mRNAs in thymocytes as a function of fetal age; the values given are rough estimates of the levels of 1.7-, 1.3- and 1.5-kb α, β and γ mRNAs respectively, relative to RNA from the 2C cell line, determined

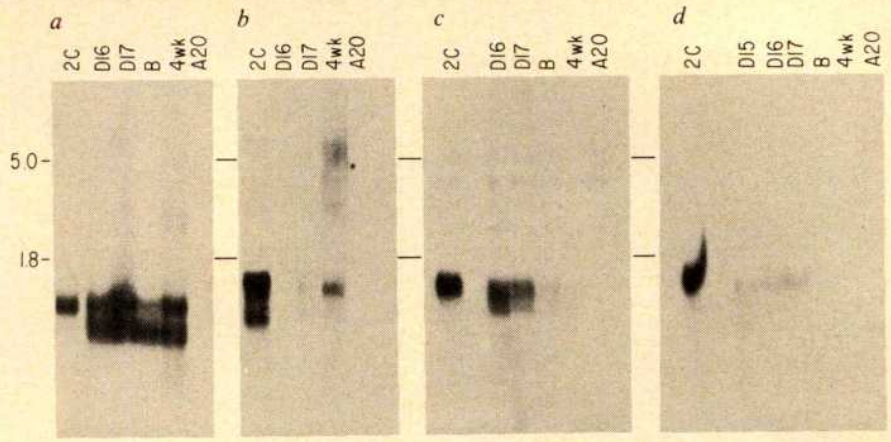

Fig. 3 Northern blot analysis of RNA samples from developing thymocytes. The probes are: *a*, C_β; *b*, C_α; *c*, C_γ; *d*, V_γ. The RNA samples are the same as those used in Fig. 2. The blots were hybridized with the same SP6-derived ^{32}P-labelled single-stranded probes as used in the ribonuclease assay (see Fig. 2 legend).

Methods. Total cellular RNA (5 μg) was denatured in formaldehyde, subjected to electrophoresis in 1.1% agarose/formaldehyde gels[43], then transferred to nitrocellulose filters, and hybridized with 3×10^7 d.p.m. of ^{32}P-labelled ssRNA probes(see Fig. 2 legend and probe diagrams) essentially as described by Melton *et al.*[40], except that the hybridized filters were washed at 70 °C rather than 65 °C in 0.1 × SSC, 0.1% SDS before autoradiography.

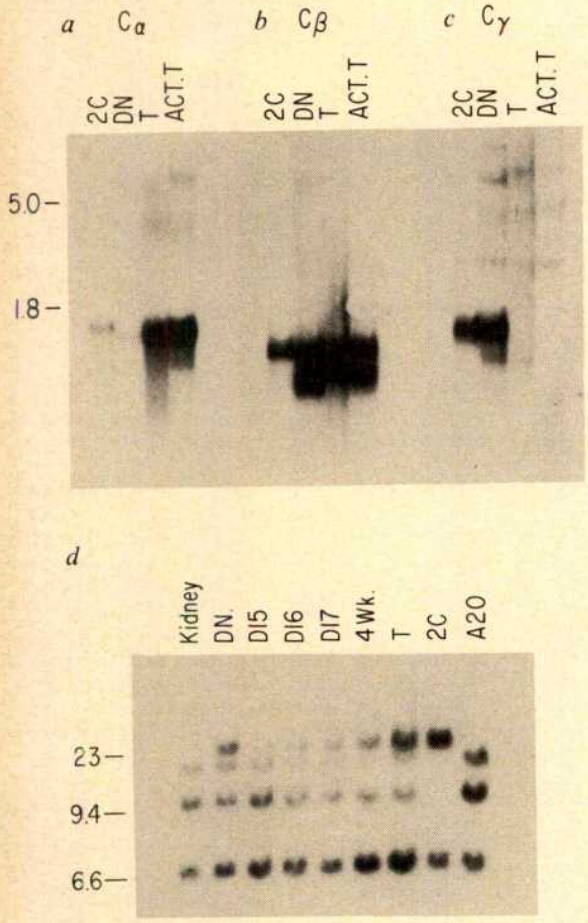

Fig. 4 *a–c*, Northern blot analysis of 5 μg of total cellular RNA from 'double-negative' adult thymocytes (DN), lymph-node T cells (T), activated T cells (ACT.T), and 2C CTLs (2C). The probes are *a*, C_α; *b*, C_β; *c*, C_γ. *d*, Rearrangements of the γ gene in thymocytes and T cells. Southern blot analysis[44] of *Eco*RI-digested genomic DNA from BALB/c kidneys, fetal thymocytes (D15, D16 and D17), 4-week-old thymocytes (4 wk) and purified lymph-node T cells from 8-week-old mice (T). DNAs from the A20 B-cell lymphoma (BALB/c-derived) and the 2C line (BALB.B-derived) were also included in the analysis. BALB/c and BALB.B embryo patterns are indistinguishable[21].

Methods. *a–c*, Northern blot analysis was performed as described in Fig. 3 legend. The preparation of the cells and RNAs were as described in Fig. 2 legend. *d*, Samples (5 μg) of each DNA preparation were digested with *Eco*RI, electrophoresed through 0.8% agarose gels, and transferred to nitrocellulose filters. The filters were hybridized with a ^{32}P-labelled, nick-translated probe corresponding to the constant region of the pHDS 34 γ cDNA clone. The probe extended from the *Ava*I site near the *J* region in pHDS 34 to the 3′ end (see Fig. 2*c*).

primarily from the Northern data (Figs 3, 4) with reference to the ribonuclease protection data (Fig. 2). The most striking feature of our results is that γ mRNA is relatively abundant only in the least mature cells of the T-cell lineage, whereas α mRNA is more abundant in mature than immature T cells. β mRNA is roughly equally abundant in each cell population examined. Whereas mRNA levels do not necessarily predict the absolute amount of the corresponding protein in a cell, the data presented here, which show shifts in the relative levels of mRNAs, probably reflect developmental regulation of the corresponding proteins.

What role might the γ gene play in T-cell recognition? Both class II-restricted helper T cells and class I-restricted CTL use a heterodimer of the α and β chains as at least part of their antigen/MHC receptor[6,7]. Although T-cell recognition is apparently not mediated by the independent recognition of MHC and antigen by independent receptors[35–37], other variations of the two-receptor model are still viable, particularly those which emphasize the constraints on physical interactions between H-2 molecules and antigens. Thus, the γ gene may encode part of a second T-cell receptor. However, based on recent evidence[38], it is unlikely that the specificity of either of the two putative receptors can be neatly assigned to either antigen or MHC determinants.

An alternative hypothesis is suggested by our data: perhaps the γ gene functions primarily in early T-cell differentiation. γ mRNA levels appear to be inversely related to α mRNA levels in thymocyte populations. Perhaps early in development a heterodimer of the γ and β chains is present on the surface of thymocytes prior to expression of the α gene. The putative γ/β heterodimer may serve as a receptor on immature thymocytes, allowing selection or suppression of clones expressing particular β chains. Later in thymocyte development, accompanying high-level expression of the α gene and a decrease in γ mRNA, the α-subunit may replace the γ subunit to form the receptor on mature T cells. It should be emphasized that the role of a γ-subunit in such a process need not be passive: for example, the γ chain may focus the γ/β-receptor complex onto MHC glycoproteins.

The finding that 2C and other CTL clones express relatively abundant levels of γ mRNA compared with normal T cells may result from the non-physiological growth conditions of the cells or, alternatively, induction of the γ gene in highly activated CTLs for purposes related to CTL function. However, the levels of γ mRNA are very low in T cells activated for 2 days with Con A (Figs 2, 4), which demonstrate significant CTL activity[39] (data not shown).

We thank Kathryn Wright for technical assistance and Ms Guliz Pamukoglu for preparing the manuscript. Identification of antigen receptor-associated structures on murine T cells

James P. Allison*‡ & Lewis L. Lanier†

The specific antigen receptor on human and murine T lymphocytes is a heterodimer of relative molecular mass (M_r) 80,000–90,000 (80–90K) composed of two 40–50K disulphide-linked glycoprotein subunits[1–8]. Peptide map analysis of the α- and β-chains of receptor isolated from distinct tumour cell lines suggests the presence of both constant and variable regions[2,9–12]. Unlike the antigen receptor on B lymphocytes (that is, surface immunoglobulin), the human T-cell antigen receptor seems to be non-covalently associated with another invariant structure recognized by monoclonal antibodies to the cell-surface antigens T3 and Leu 4 (refs 4, 5, 9, 12). Meuer *et al.*[5] have demonstrated co-modulation of the T3 structure and T-cell antigen receptor using anti-clonotypic and anti-T3 monoclonal antibodies. Furthermore, immunoprecipitation with anti-T3 weakly co-precipitates a small amount of the 80–90K heterodimer in certain conditions[4,9,12]. The murine homologue of the Leu 4/T3 structure has not been identified, although Gunter *et al.* have suggested that Thy-1 may be the counterpart of Leu 4/T3 (ref. 13). Here we describe a Leu 4/T3-like structure, distinct from Thy-1, associated with the T-cell receptor of a murine T-lymphoma cell line.

‡ Present address: Department of Microbiology and Immunology, University of California, Berkeley, California 94720, USA.

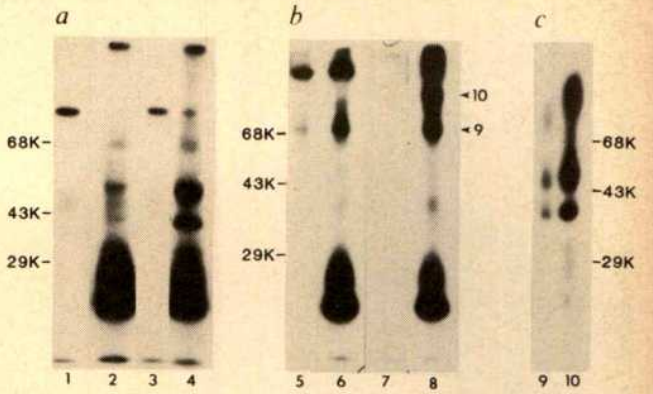

Fig. 1 SDS-PAGE analysis of human Leu 4 and associated structures. *a*, Reduced samples; *b*, non-reduced samples, run on 10% gels. Lanes 1, 2, 5, 6, sham-treated cells; lanes 3, 4, 7, 8, DTBP crosslinked cells; lanes 1, 3, 5, 7, P3 IgG1; lanes 2, 4, 6, 8, anti-Leu 4. *c*, Bands at arrows in *b* were cut out of dried gels, rehydrated in SDS sample buffer containing 50 mM dithiothreitol for 1 h, then loaded into sample wells and resolved on 12.5% gels.
Methods. Human HPB-ALL T-leukaemia cells (provided by Dr Jun Minowada) were labelled with ^{125}I (Amersham) using lactoperoxidase (Sigma)-catalysed radioiodination[14]. Half of the labelled cells were incubated for 30 min at room temperature (25 °C) in phosphate-buffered saline (PBS, 0.1 M phosphate, *p*H 7.5) containing 10 mM DTBP (Pierce Chemicals) as described by Wang and Richards[15], with minor modifications. Control cells were incubated in PBS without DTBP. After washing in 5 mM ammonium acetate/0.1 M PBS(*p*H 7.3) to inhibit the reaction, cells were placed in lysate buffer (0.05 M Tris-HCl, *p*H 8.0) containing 0.15 M NaCl, 1 mM EDTA (Sigma), 0.02% NaN, 0.5% Nonidet P-40 (Sigma), 20 KIU ml^{-1} aprotinin (Sigma) and 50 mM *N*-ethylmaleimide (Sigma) for 20 min at 4 °C. Lysates were centrifuged at 13,000*g* for 15 min, pre-cleared for 10 min with formalin-fixed *S. aureus* (Enzyme Center), then incubated at 4 °C with anti-Leu 4 antibody (Becton Dickinson Monoclonal Center) or P3X IgG1 myeloma protein. Immune complexes were isolated from lysates by incubation with rabbit anti-mouse IgG-coated formalin-fixed *S. aureus*. After washing, bound material was eluted by boiling in sample buffer containing 2.3% SDS (Bio-Rad) with or without 5% 2-mercaptoethanol (Sigma). Samples were analysed by SDS-PAGE as described by Laemmli[24]. Protein standards (Sigma) were included for M_r determination. Gels were dried and autoradiographed at −70 °C on Kodak XR film using intensifying screens (Cronex Lightning Plus).

The human T-cell antigen-specific receptor co-modulates on the cell surface with a 20–25K glycoprotein structure identified by the anti-T3 monoclonal antibody[5]. Immunoprecipitation of the T3 antigen from ^{125}I-labelled T-cell lines also weakly co-precipitates a small amount of the disulphide-linked 80–90K heterodimer under certain non-stringent conditions[4,9,12]. Here, we use chemical crosslinkers to perform a nearest-neighbour analysis of structures associated with human and murine T-cell receptor. We labelled the cell surface proteins of murine or human T cells with ^{125}I using lactoperoxidase-catalysed radioiodination[14], then crosslinked them using the cleavable reagent dimethyl dithiobispropionimidate (DTBP)[15]. The cells were solubilized with detergent and immunoprecipitates obtained with monoclonal antibodies and analysed by SDS-PAGE. Figure 1 shows such an analysis of human T-leukaemia HPB-ALL cells immunoprecipitated with an anti-Leu 4 antibody. Under reducing conditions (*a*), immunoprecipitates obtained from crosslinked cells contained significant amounts of two additional proteins of 37 and 45K in addition to the major Leu 4 bands at 22 and 27K. Lesser amounts of the 37 and 45K components were observed in the sham-treated controls. The properties of these proteins are consistent with the clonotypic heterodimer subunits described by Meuer *et al.*[4,5]. Immunoprecipitations of crosslinked and sham-treated samples with monoclonal antibodies to Leu 1 (T1), Leu 2 (TB), Leu 3 (T4) and Leu 5 (T11) failed to co-precipitate the 37 and 45K components, indicating

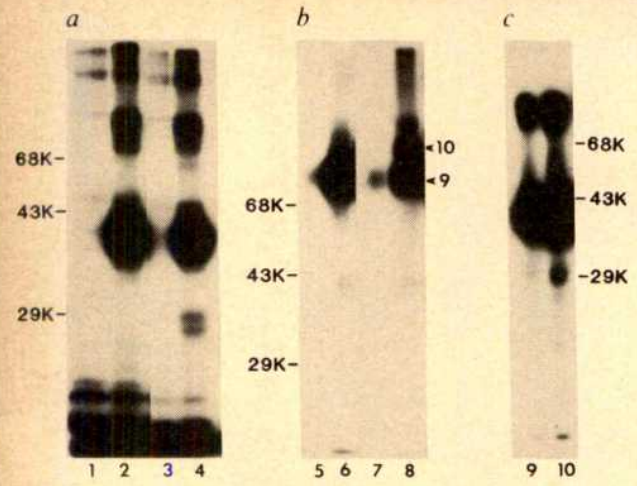

Fig. 2 SDS-PAGE analysis of T-cell receptor and associated structures from murine C6VL lymphoma cells. *a*, Reduced samples; *b*, non-reduced samples, resolved on 10% gels. Lanes 1, 2, 5, 6; sham-treated cells; lanes 3, 4, 7, 8, DTBP crosslinked cells; lanes 1, 3, 5, 7, P3 IgG1; lanes 2, 4, 6, 8, 124-40. *c*, Bands at arrows in *b* were cut out, rehydrated and reduced and contents resolved on 12.5% gels as described in Fig. 1 legend. C6VL lymphoma cells were radiolabelled, crosslinked and solubilized as described for Fig. 1. Crosslinked and sham-treated lysates were immunoprecipitated with the anti-T-cell receptor 124-40 antibody or P3X IgG1 myeloma protein.

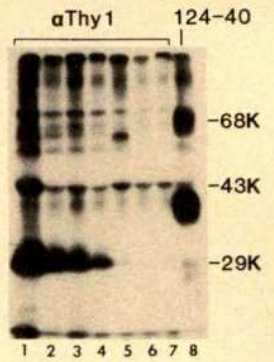

Fig. 3 Sequential immunoprecipitation with anti-Thy-1.2 and anti-T-cell receptor 124-40. Lanes 1–7, sequential immunoprecipitations with anti-Thy-1.2; lane 8, immunoprecipitation of supernatant with anti-receptor antibody 124-40. Thy-1.2 antigen was depleted from crosslinked C6VL lysate by precipitation with rat anit-mouse Thy-1.2 (clone 30-H12) antibody-coated *S. aureus*. After complete removal of all Thy-1.2 antigen, the depleted lysate was incubated with an anti-clonotypic antibody, 124-40, to the T-cell antigen receptor on C6VL, followed by rabbit anti-IgG/*S. aureus*. The bound material was eluted and analysed by SDS-PAGE under reducing conditions using a 10% polyacrylamide gel.

the specificity of the reaction (data not shown). That the additional bands were obtained as a consequence of crosslinking to the Leu 4 structure is supported by additional data. As shown in Fig. 1*b*, analysis of immunoprecipitates under non-reducing conditions revealed that both crosslinked and sham-treated cells yielded, in addition to the Leu 4 bands, an additional component at 83K, as expected for the T-cell receptor heterodimer co-precipitating as a result of non-covalent association with Leu 4. The crosslinked sample, but not the sham-treated sample, yielded an additional component of 117K, a size consistent with that expected for a covalent complex of the receptor heterodimer and Leu 4. This conclusion is supported by the data in Fig. 1*c*. Cleavage of the 83K component by reduction of the gel slice followed by SDS-PAGE indicated that this component was indeed composed of the receptor heterodimer subunits, whereas similar treatment of the 117K band yielded Leu 4-like components in addition to the receptor heterodimer subunits. Taken together, these data show that chemical crosslinking can demonstrate the association between Leu 4 and receptor-like components on the surface of human T cells.

We next sought to determine whether additional structures might be associated with the murine T-cell receptor heterodimer. We have described previously the properties of a murine anti-clonotypic monoclonal antibody 124-40, which reacts exclusively with the receptor of the murine T lymphoma C6VL[1,2]. This antibody immunoprecipitates a 80K glycoprotein composed of disulphide-linked subunits (39 and 41K)[1,2]. C6VL cells were radioiodinated, crosslinked with DTBP, solubilized and immunoprecipitated with antibody 124-40. As shown in Fig. 2, crosslinked, but not sham-treated, samples contain two additional components of 24 and 29K that co-precipitate with the T-cell specific heterodimer. These structures are not present in the non-specific antibody control. Anaylsis of the samples under non-reducing conditions (Fig. 2*b*) indicated the presence of the 80K receptor heterodimer, and, in the crosslinked sample only, an additional band of ~115K consistent with that expected for the receptor heterodimer and associated structures. As shown in Fig. 2*c*, reductive cleavage of the 115K band yields a band corresponding to the receptor subunits as well as additional components similar to those obtained in Fig. 2*a*. These results indicate that these structures may be a component of the murine T-cell antigen receptor complex similar to the Leu 4/T3 antigens that are associated with the human T-cell receptor heterodimer structure.

Recently, Gunter *et al.*[13] have proposed that murine Thy-1 may be the structural and functional counterpart to the human Leu 4/T3 antigen. This hypothesis was based on the observations that: (1) Leu 4/T3 and Thy-1 are present on all mature human and murine T lymphocytes, respectively[16–18]; (2) some monoclonal antibodies against both human Leu 4/T3 and murine Thy-1 are mitogenic[19–21]; (3) Leu 4/T3 and Thy-1 have a similar M_r (20–30K); (4) both anti-Leu 4 and UCHT-1 antibodies react with cerebellar Purkinje cells[22] (like the anti-brain reactivity of anti-Thy-1; ref. 16). However, unlike anti-Leu 4/T3 antibodies[18], G7 (anti-Thy-1) described by Gunter *et al.*[13] did not block specific T-cell antigen recognition, did not modulate readily the Thy-1 antigen on the cell surface of T lymphocytes and did not co-precipitate T-cell receptor heterodimer structures.

To address directly the relationship of the Thy-1 molecule and the two structures that co-precipitate with the T-cell receptor heterodimer from crosslinked C6VL membrane, we performed immunodepletion and peptide map analyses. As shown in Fig. 3, sequential immunoprecipitation with anti-Thy-1.2, which removed all Thy-1.2 antigen from the lysate, failed to remove the T-cell receptor heterodimer or the associated Leu 4/T3-like structures from crosslinked C6VL membrane lysates. These results indicate that the receptor is not associated with Thy-1 molecules bearing antibody-accessible 1.2 allotypic determinants. In view of the fact that the larger of the Leu 4/T3-like components was similar in electrophoretic mobility to Thy-1, it seemed possible that Thy-1 molecules, perhaps in a configuration resulting in the masking of the allotypic determinants, might comprise a portion of the receptor complex detected in the crosslinked precipitates. Therefore, we prepared peptide maps of each of the components for comparison of primary structure. The T3-like α-(29K) and β-(24K) components and Thy-1.2 were isolated from radioiodinated, crosslinked C6VL cells by immunoprecipitation with clonotypic antibody 124-40 or 30-H12, respectively, and purified by SDS-PAGE. Gel slices containing the proteins were subjected to partial proteolytic digestion and peptides resolved by SDS-PAGE as described previously[23]. Maps of peptides obtained with papain, *Staphylococcus aureus* V8 protease and subtilisin are presented in Fig. 4. The patterns obtained with 24K β-T3 are clearly different from the Thy-1.2 pattern with all three proteases. For the 29K

Fig. 4 Peptide map analysis of Thy-1.2 and the Leu 4/T3-like structures. *a*, Papain digests. Lanes 1, 4, 7, no protease; lanes 2, 5, 8, 5 μg papain; lanes 3, 6, 9, 25 μg papain. *b*, *S. aureus* V8 protease digests. Lanes 1, 3, 5, 5 μg protease digests; lanes 2, 4, 6, 25 μg protease. *c*, Subtilisin digests. Lanes 1, 3, 5, 10 μg subtilisin; lanes 2, 4, 6, 50 μg subtilisin. The Thy-1.2 and the two Leu 4/T3-structures associated with the T-cell antigen receptor on C6VL tumour were cut from gels and peptide map analaysis performed essentially as described by Cleveland *et al.*[23]. Peptides were resolved by SDS-PAGE on 15% gels.

α-T3, the overall patterns obtained with papain (Fig. 4*a*) and subtilisin (Fig. 4*c*) are similar to Thy-1.2, although the major fragments of Thy-1.2 are somewhat smaller. The patterns obtained with V8 protease (Fig. 4*b*), however, are quite distinct. These results indicate that the Leu 4/T3-like components are both different from Thy-1.2 in primary structure and represent distinct cell-surface components.

Our experiments demonstrate conclusively for the first time that in the mouse, as in man, additional components are associated with the heterodimer structure implicated as the T-cell antigen receptor. Further structural and functional studies of the murine equivalent of this Leu 4/T3-like structure await production of an antibody against this antigen, which will be facilitated greatly by crosslinking techniques in conjunction with anti-clonotypic monoclonal antibodies to obtain the structure for immunization.

This work was supported by grant CA 26321 from the NIH and the Becton Dickinson Monoclonal Center, Inc. We thank Ms Linda Ridge and Ms Jane Gross-Pelose for assistance, Ms Judy Ing for preparation of figures and Ms Patricia Mutschink for preparation of the manuscript.

Direct evidence that reverse cholesterol transport is mediated by high-density lipoprotein in rabbit

N. E. Miller, A. La Ville & D. Crook

Department of Chemical Pathology and Metabolic Disorders, St Thomas' Hospital Medical School, London SE1 7EH, UK

Mammalian cells obtain cholesterol for membrane synthesis mostly via the receptor-mediated endocytosis of low-density lipoprotein (LDL)[1]. Macrophages and vascular endothelium additionally have receptors that recognize certain modified forms of LDL (for example, acetyl-LDL)[2,3]. The process by which cholesterol returns from peripheral cells to hepatocytes (reverse cholesterol transport) has not been established; although tissue culture studies have favoured high-density lipoprotein (HDL) as the principal vehicle[4,5], the *in vivo* evidence for this is meagre. When cholesterol-loaded macrophages are incubated in medium containing plasma, cholesterol moves from the cells to HDL and is then esterified by lecithin/cholesterol acyltransferase[6]. The accumulation of cholesteryl esters in the particles increases their size and decreases their density; enrichment with apoprotein E (apo E) also occurs, producing a decrease in electrophoretic mobility[7,8]. We now report that similar changes occur in the circulating HDL of rabbits, when their peripheral tissues are loaded with cholesterol by intravenous (i.v.) injection of acetylated or native human LDL. This result suggests that HDL is involved in reverse cholesterol transport *in vivo*.

The experiments were carried out in six New Zealand White rabbits (*Oryctolagus cuniculus*; 3.2–4.7 kg), maintained on Sg1

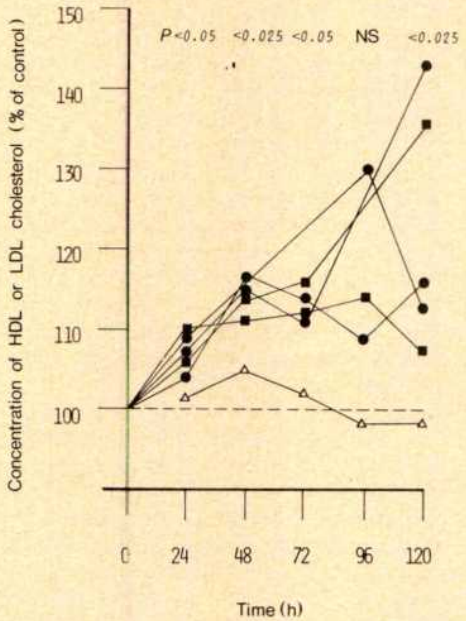

Fig. 1 Increases in the concentration of cholesterol in serum HDL measured by preparative ultracentrifugation (d = 1.063–1.21 g ml^{-1}) in five rabbits after a single i.v. injection (at time zero) of acetylated (●) or native (■) human LDL. The amount of cholesterol infused was 0.14–0.52 mmol (mean 0.29 mmol, 111 mg). The results are presented as percentages of the concentrations that existed at the time of injection. The P values at each time point were obtained by Student's paired t-test analysis of the absolute HDL cholesterol concentrations against the values at time zero. Mean concentrations of LDL cholesterol (d 1.019–1.063), in which there was no statistically significant change, are also given (△). The mean HDL cholesterol concentration (with the s.e.) at 0, 24 and 120 h was 0.88 (0.22), 0.94 (0.24) and 1.06 (0.24) mmol l^{-1} respectively; the corresponding values for LDL cholesterol were 0.79 (0.30), 0.68 (0.22) and 0.65 (0.20) mmol l^{-1}. Mean coefficient of variation of duplicate HDL cholesterol assays-3.8%.

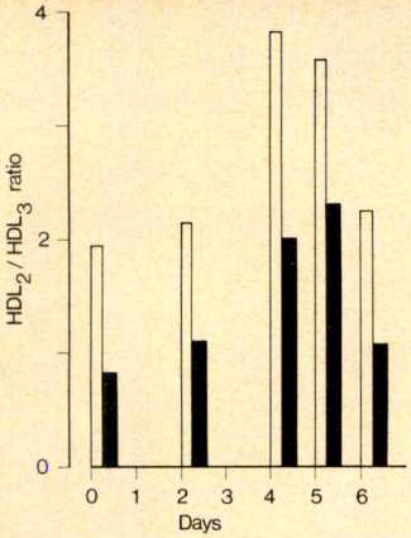

Fig. 2 Increase in the ratio of HDL_2 ($d = 1.063$–1.125 g ml^{-1}) to HDL_3 ($d = 1.125$–1.21 g ml^{-1}), measured in terms of total cholesterol content (open bars) and total protein content (closed bars) in a rabbit during the 6 days after a single i.v. injection of acetylated human LDL (0.49 mmol cholesterol, 189 mg). Results are the means of duplicate determinations.

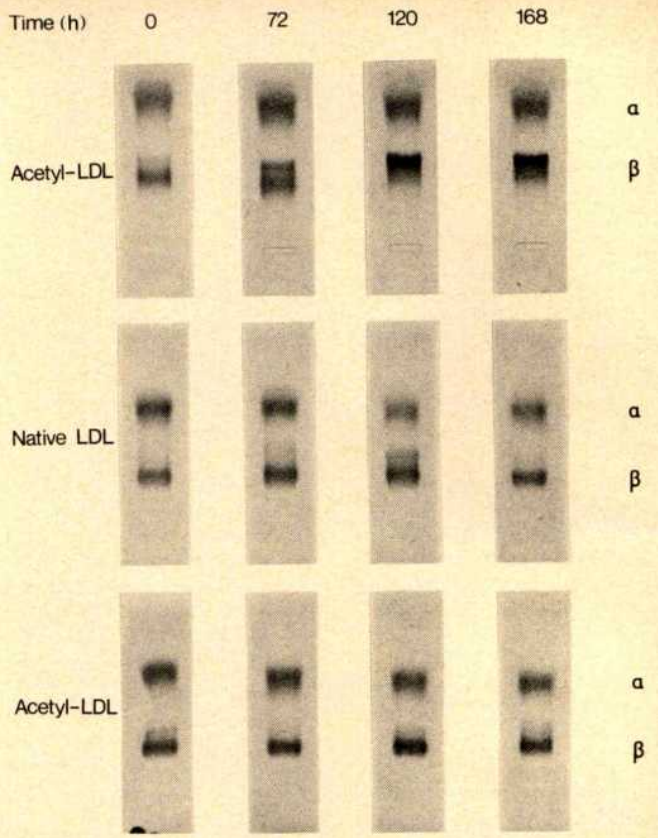

Fig. 3 Representative results from agarose gel electrophoresis of serum lipoproteins, using samples of serum collected immediately before, and at different times after, a single i.v. injection of acetylated or native human LDL into rabbits. (Serum samples were loaded at the bottom of the gels shown.) HDL migrates as the α band, and LDL as the β band. In all animals ($n = 5$) the mobility of HDL decreased progressively with time. In the pooled data, the mean electrophoretic mobilities of HDL (measured from the leading edge of the α band, and expressed relative to the pre-injection value) at 48, 72, 96, 120 and 168 h were (s.e. in parentheses): 98.5 (0.51), 96.6 (0.56), 94.0 (1.09), 91.0 (1.53) and 88.6 (1.86)%. By Student's paired t-test, the results obtained at all time points beyond 48 h were significantly different from those at time zero ($P < 0.05$ at 72, 96 and 120 h; $P < 0.02$ at 168 h). In some animals variable changes in the staining pattern of the β band were also observed; the significance of this finding, which was not associated with any change in LDL cholesterol concentration, is not clear, but one possibility is that it reflects the re-appearance in plasma of small amounts of modified LDL released from vascular cells by retroendocytosis[34].

rabbit diet (Grain Harvested Ltd, Canterbury, UK). LDL of density (d) 1.019–1.063 g ml^{-1} was isolated from human plasma by sequential preparative ultracentrifugation, dialysed against 0.15 M NaCl, and sterilized by filtration[9]. Acetyl-LDL was prepared using acetic anhydride, and agarose gel electrophoresis was performed to confirm that acetylation was complete[10]. Total cholesterol levels in serum LDL, very low-density lipoprotein (VLDL, $d < 1.006$), HDL (d 1.063–1.21) and the two major density subclasses of HDL (HDL_2, d 1.063–1.125; HDL_3, d 1.125–1.21) were determined by a cholesterol esterase/oxidase procedure (Boehringer-Mannheim, Cat. no. 237 574), after isolation of the lipoproteins by preparative ultracentrifugation[9]. In some animals, HDL cholesterol was also assayed after precipitation of VLDL and LDL with heparin and $MnCl_2$ (ref. 11). HDL protein was assayed according to Lowry *et al.*[12]. Electrophoresis of serum lipoproteins in agarose gel was performed for 30 min at 90 V (15 mA) using Corning Universal Agarose Film (1% agarose, 5% sucrose and 0.035% Na_2EDTA, (w/v) in 0.065 M barbital buffer, pH 8.6), followed by staining with 0.4% Fat Red 7B in methanol. Neutral and acidic steroids in faecal collections were quantified by gas–liquid chromatography, using 5α-cholestane as the internal standard[13,14].

Four animals were given acetylated LDL, and the remaining two native (unmodified) human LDL. All injections were made into an ear vein over 3–5 mins (total vol. 5–18 ml). The amounts infused (0.14–0.52 mmol cholesterol; mean 0.32) averaged 8.4 times the circulating LDL pool. As anticipated[15,16], both native and acetylated human LDL were cleared rapidly from the circulation, the plasma LDL cholesterol concentrations 24 h after injection being 79–150% (mean 101%) of initial values. The rationale behind giving acetylated and heterologous LDL, rather than the native homologous lipoprotein, was to target the cholesterol load away from hepatocytes and towards other cells. Although it was not possible to examine the tissue sites of uptake in our animals, it can be assumed from previous work that most of the acetyl-LDL will have been cleared by macrophages and vascular endothelium; these are the only cell types known to possess receptors with high affinity for acetyl-LDL[2,3,16,17], and acetyl-LDL does not bind to the native LDL receptors of other peripheral tissues and hepatocytes[2,17,18]. Accordingly, 10 min after injecting radioiodinated acetyl-LDL into rats, Van Berkel *et al.*[16] recovered 80% of the radioactivity in the non-parenchymal cells of the liver. Using ^{14}C-cholesteryl oleate-labelled acetyl-LDL, Blomhoff *et al.*[19] subsequently showed that this largely reflected uptake by vascular endothelium (60%), from which the cholesterol derived from hydrolysis of the lipoprotein was then released; uptake by hepatocytes was 15%. There also exists evidence that even unmodified human LDL is cleared largely by cells other than hepatocytes when injected into animals, although the organ sites of catabolism are distributed more widely than are those of acetyl-LDL[15,20–22]. Consistent with these reports was our own finding that the increments in faecal cholesterol and bile acid excretion during the 72 h after the injections accounted for <6% and <12% of the administered cholesterol in the case of acetyl-LDL and native LDL, respectively.

Following clearance of the infusate from the circulation, the plasma LDL concentration showed no significant change during the following 120–144 h (see Fig. 1 legend), nor did the level of VLDL cholesterol change. In contrast, HDL cholesterol, as measured by ultracentrifugation, progressively increased in all animals by a mean of 28% (range 14–43%; $P < 0.025$) (Fig. 1); this was accompanied by a rise in the HDL_2/HDL_3 ratio, measured in terms of both cholesterol and protein content (Fig. 2), indicating a decrease in the mean hydrated density of the particles. Concomitantly, the electrophoretic mobility of HDL decreased gradually in all animals (see Fig. 3).

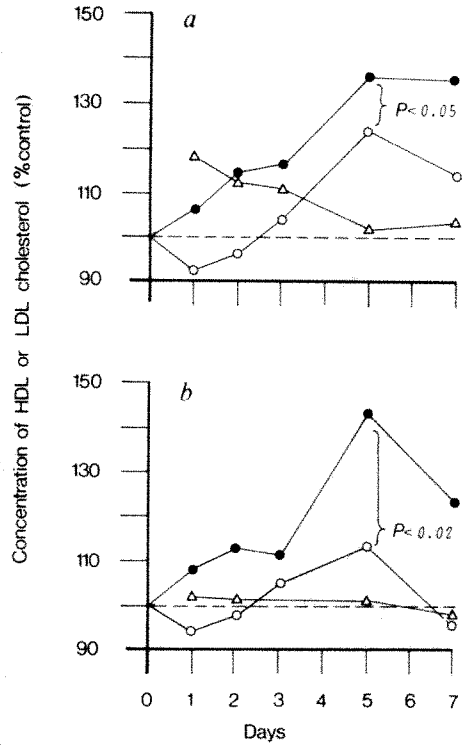

Fig. 4 Changes in the serum concentrations of HDL cholesterol (●, ○) and LDL cholesterol (△) in two rabbits, after i.v. injection of native (*a*) or acetylated (*b*) human LDL. The HDL values represented by the closed circles were obtained by ultracentrifugation ($d = 1.063$–1.21 g ml^{-1}); those represented by the open circles were obtained by assaying the cholesterol content of the supernatant after treatment of serum with heparin and $MnCl_2$ (ref. 11). LDL was isolated by ultracentrifugation (d 1.019–1.063). The P values were obtained by Student's paired t-test comparison of results obtained by the two different methods at the same time points. In the pooled data from four such experiments, the mean HDL cholesterol concentrations by ultracentrifugation at times 0, 72 and 120 h were 1.04 (0.19), 1.18 (0.22) and 1.26 (0.17) mmol l^{-1} respectively (s.e. in parentheses); the corresponding values determined using heparin-$MnCl_2$ were 0.98 (0.12), 1.01 (0.14) and 1.10 (0.17) mmol l^{-1}.

These changes in HDL are identical to those that occur in animals and man during consumption of cholesterol-rich diets[23] and in tissue culture when canine plasma is incubated with cholesterol-loaded mouse peritoneal macrophages[8]. In both cases there is accumulation of large HDL particles, rich in cholesteryl esters and apo E, which *in vitro* seem to be derived from HDL_3. As these particles differ functionally from HDL_3 in being no longer able to promote a net efflux of cholesterol from cultured cells[24], and in being catabolized in the perfused rat liver via high-affinity apo E receptors[25], it has been postulated that they represent the end-products of HDL metabolism during reverse cholesterol transport.

Apo E is synthesized in several tissues at a rate which is a function of cell cholesterol content[2,7,26]; it normally represents only a minor component of plasma total HDL, which can be divided into two subclasses on the basis of the presence or absence of the apoprotein. The results in Fig. 4 provide indirect evidence that the rise in total HDL cholesterol observed in our experiments was associated with a disproportionate increase in the apo E-containing subclass. HDL with apo E differs from HDL without apo E in being precipitable by heparin and $MnCl_2$ (ref. 23). When the concentrations of HDL cholesterol remaining in heparin-$MnCl_2$ supernatants were measured in four rabbits before and after injection of acetylated or native human LDL (two experiments with each), the relative increments were significantly smaller than those of total HDL cholesterol quantified by preparative ultracentrifugation.

Recently, the suggestion that HDL retards atherogenesis in man by removing cholesterol from the lesions[27] has received increasing attention as a result of epidemiological reports of an inverse relationship between the plasma HDL cholesterol concentration and the incidence of coronary heart disease[28,29]. Although the ability of HDL to remove cholesterol from cells is well documented *in vitro*[4,5], the *in vivo* evidence for such a role of HDL has been limited to demonstrations of a preferential transfer of radioactive cholesterol from tissues to plasma or lymph HDL in man[30,31], and to studies of the composition of peripheral lymph lipoproteins[32,33]. Our present finding that the delivery of cholesterol to peripheral tissues is followed by changes in HDL similar to those seen when the lipoprotein is incubated with cholesterol-loaded macrophages provides the first direct evidence that the events observed *in vitro* represent the normal process of reverse cholesterol transport, and suggests a model system for studying the efficiency of the process under different conditions *in vivo*.

We thank Dr D. Mitchell for help with the faecal steroid assays.

Structure and transcription of human papillomavirus sequences in cervical carcinoma cells

Elisabeth Schwarz, Ulrich Karl Freese, Lutz Gissmann, Wolfgang Mayer, Birgit Roggenbuck, Armin Stremlau & Harald zur Hausen

Institut für Virusforschung, Deutsches Krebsforschungszentrum, Im Neuenheimer Feld 280, D-6900 Heidelberg 1, FRG

DNA of human papillomavirus (HPV) types 16 and 18 has been found closely associated with human genital cancer[1,2], supporting the concept that members of this virus group are key factors in the aetiology of genital cancer[3]. HPV 18 DNA sequences were also detected in cell lines derived from cervical cancer[2]. We have

now analysed these cell lines, HeLa, C4-1 and 756, for the structural organization and transcription of the HPV 18 genome and we find that the HPV 18 DNA is integrated into the cellular genome and is amplified in HeLa and 756 cells. Almost the complete HPV 18 genome seems to be present in 756 cells, with the early region being disrupted into two portions in each integrated copy. In HeLa and C4-1 cells, a 2–3 kilobase (kb) segment of HPV 18-specific sequences is missing from the E2 to L2 region. HPV 18 sequences are specifically transcribed from the E6–E7–E1 region into poly(A)$^+$ RNAs of 1.5–6.5 kb. Hybridization analysis of cDNA clones indicated that some of the transcripts are composed of HPV 18 and cellular sequences. In addition, poly(A)$^+$ RNA hybridizing with HPV 16 DNA was found in two out of three cervical carcinoma biopsies.

Two-dimensional agarose gel electrophoresis[4] and caesium chloride/ethidium bromide density gradient centrifugation[5,6], with subsequent analysis of the gradient fractions for the presence of HPV 18 sequences, showed that HPV 18 DNA is present in an integrated state within the chromosomal DNA of all three cervical cancer cell lines examined (data not shown). C4-1 cells were estimated to contain about one copy of HPV 18 DNA per cell, whereas in 756 and HeLa cells the HPV 18 sequences are amplified about 10–50-fold.

To determine which parts of the HPV 18 genome are present in the cell lines, blot hybridizations were performed using individual subgenomic fragments of HPV 18 DNA as nick-translated probes. Partial sequence analysis of prototype HPV 18 DNA and comparison with the known nucleotide sequence of the related genital papillomavirus HPV 6b (ref. 7, see Fig. 1*a*) allowed an unequivocal assignment of viral genome segments to each HPV 18 restriction fragment (Fig. 1*b*). The hybridization analysis then showed (Fig. 2) that all three cell lines contain (1) the HPV 18 non-coding region (hybridization of the cellular DNAs with the 1.1-kb *Bam*HI fragment) believed to harbour important regulatory elements for viral transcription (for review see ref. 8) and (2) the first part of the early region, including open reading frames E6, E7 and E1 (hybridization with the 2.4-kb *Bam*HI/EcoRI fragment). HeLa DNA seems to contain two different populations of HPV 18 sequences, one corresponding in its restriction enzyme cleavage sites (*Bam*HI, *Eco*RI) to the cloned HPV 18 prototype DNA and the other showing a modified pattern of cleavage sites (as seen by the hybridization of the 1.1-kb *Bam*HI fragment to two *Bam*HI fragments in HeLa DNA, Fig. 2*B*). Modifications in some HPV 18 cleavage sites were also observed in 756 (loss of the *Eco*RI site) and C4-1 DNA (data not shown). The lack of positive hybridization with the 1.4-kb *Hin*cII fragment (Fig. 2*B*) indicates the absence of HPV 18-specific sequences from the distal part of the early region (E2, E4) and from the late region (L2) in HeLa and C4-1 cells. In contrast, 756 cells seem to harbour most or even all of the HPV 18 DNA, as shown by hybridization of the 1.4-kb and 1.15-kb *Hin*cII fragments, respectively. The hybridization experiments suggest that HeLa and C4-1 cells contain only an incomplete HPV 18 genome with deletion of parts of the early and late region. However, we cannot rule out the possibility that these two cell lines contain the complete genome of a mosaic-like papillomavirus which, in the L1–E1 region, is composed of HPV 18-specific sequences and in the E2–L2 region is composed of sequences which do not cross-hybridize with HPV 18 in stringent conditions.

The hybridization data enabled us to deduce the possible locations of the viral integration sites. The 1.15-kb prototype HPV 18 fragment was the only probe that hybridized with two *Bam*HI fragments of 756 DNA (9 and 21 kb, respectively, Fig. 2*A*), indicating that opening of the circular HPV 18 DNA for integration has occurred in that region. Similarly, the hybridization patterns of HeLa and C4-1 DNA obtained with the 1.15-kb probe (Fig. 2*A*, *B*) suggest that one breakpoint of the integrated HPV 18 DNA is located downstream of the E6–E1 region, in the segment forming the 1.15-kb fragment, whereas in these two cell lines, because of the absence of some portions of HPV 18 sequences, the opposite viral integration sites are located in a late region segment covered by the 1.8-kb *Hin*cII/*Bam*HI fragment. Alternatively, in HeLa and C4-1 cells, the transition point between the HPV 18-related and unrelated sequences of a mosaic-like papillomavirus would be located in the 1.15-kb segment.

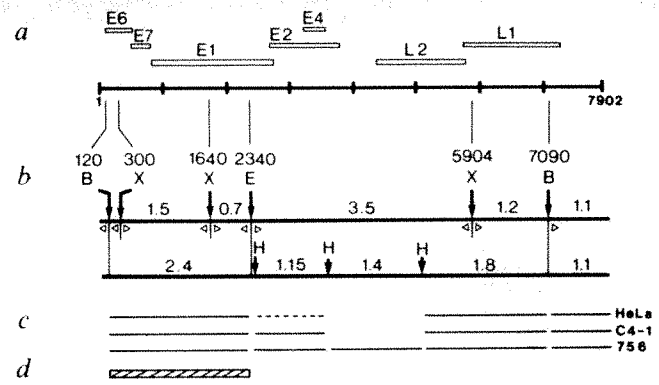

Fig. 1 ***a***, Arrangement of open reading frames in HPV 6b DNA as determined by nucleotide sequence analysis[7]. E and L denote open reading frames in the putative early and late regions, respectively. The circular 7,902-base pair (bp) HPV 6b sequence is linearized at nucleotide position 1 located in the non-coding region. ***b***, Alignment of HPV 18 DNA with HPV 6b according to nucleotide sequence homologies. Restriction fragments generated by cleavage with *Bam*HI (B), *Xba*I (X) and *Eco*RI (E) were used for partial sequence analysis of HPV 18 DNA (upper line). The fragment ends for which nucleotide sequence data were obtained (60–150 nucleotides from each 3′-terminally labelled end) are indicated by open triangles. 3′-Terminal labelling was performed in 50 mM Tris-HCl *p*H 7.5, 100 mM NaCl, 10 mM $MgCl_2$, 1 mM dithiothreitol, with 50 μCi [α-^{32}P]dTTP (specific activity 3,000 Ci mmol^{-1}, Amersham) and 5 U DNA polymerase I (Klenow fragment, Boehringer) at 20 °C for 30 min. The partial chemical cleavage reactions for DNA sequencing were performed as described elsewhere[15]. The nucleotide positions in HPV 6b DNA homologous to the *Bam*HI, *Xba*I and *Eco*RI sites in HPV 18 DNA are indicated above the restriction sites. Isolated subgenomic fragments generated by cleavage of HPV 18 DNA with *Bam*HI, *Eco*RI and *Hin*cII (H, lower line) were used as nick-translated probes for hybridization with DNA and RNA from the HeLa, C4-1 and 756 cervical cancer cell lines. Sizes of restriction fragments are given in kb. ***c***, ***d***, Schematic summary of blot hybridization experiments performed with DNA (*c*) and poly(A)$^+$ RNA (*d*) from the three cell lines. HPV 18 fragments hybridizing to cellular DNA (see Fig. 2*A*, *B*) are represented by horizontal bars. The dashed line denotes very weak hybridization. The 2.4-kb *Bam*HI/*Eco*RI fragment found to be the only fragment hybridizing to poly(A)$^+$ RNA from HeLa, C4-1 and 756 cells (Fig. 3) is indicated by a cross-hatched bar.

Although the hybridization and mapping data are compatible with an overall co-linearity of the integrated HPV 18 sequences with the prototype HPV 18 DNA, they do not eliminate the possibility of sequence rearrangements that eventually may be reflected by some of the modifications in restriction enzyme cleavage sites observed in the integrated HPV 18 sequences. Figure 2C shows a scheme for the integrated HPV 18 DNA in the three cell lines. We assume that only one chromosomal integration site is present in C4-1 and 756 cells, respectively, but there is probably more than one in HeLa cells. The hybridization pattern of HeLa and 756 DNA further suggested that the amplified HPV 18 sequences are not arranged directly in tandem, but that the amplification includes flanking cellular sequences.

To analyse HPV 18 transcription in the three cell lines, poly(A)$^+$ RNA was isolated and subjected to Northern blot hybridization. Hybridization with total HPV 18 DNA as probe revealed for each cell line a characteristic RNA pattern showing two or three major RNA species (HeLa, 1.6 and 3.5 kb; 756, 1.5 and 6.5 kb; C4-1, 1.5, 4.2 and 5.5 kb). When the five subgenomic fragments of prototype HPV 18 DNA (Fig. 1*b*) were used as nick-translated probes, exactly the same RNA pattern was obtained with the 2.4-kb *Bam*HI/*Eco*RI fragment probe

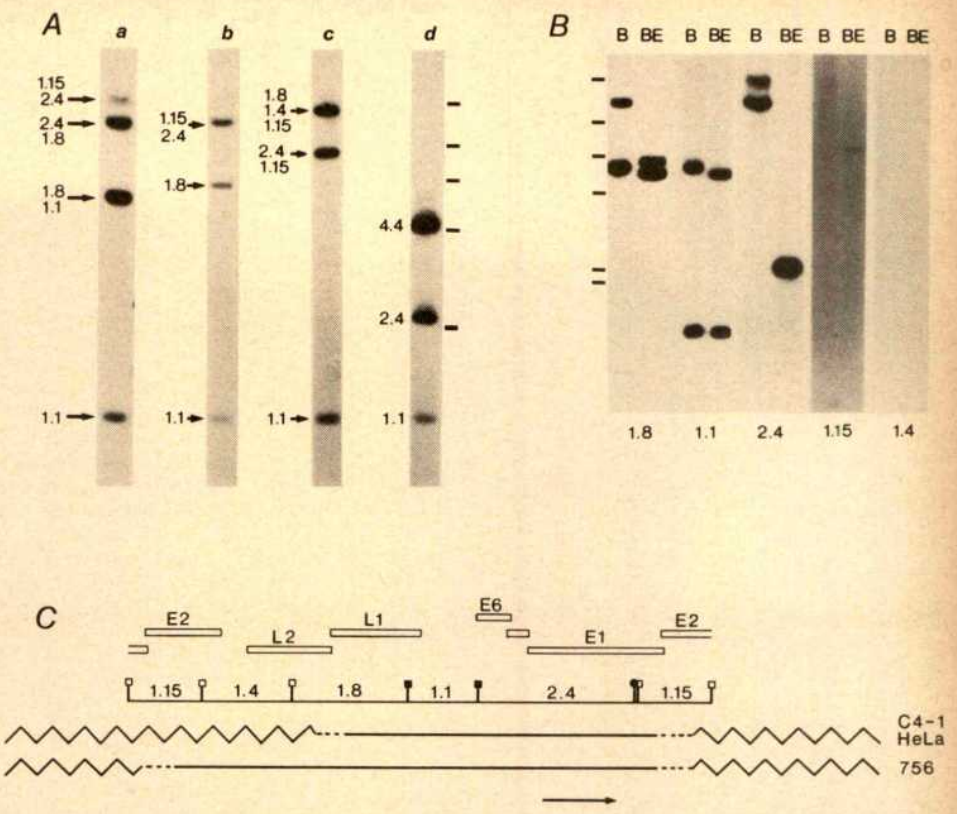

Fig. 2 *A*, Hybridization of DNA from human cervical cancer cell lines with HPV 18 DNA as probe. *B*, Hybridization of HeLa DNA with subgenomic fragments of HPV 18 DNA as probes. *C*, Possible integration patterns of HPV 18 DNA sequences into the cellular genome in HeLa, C4-1 and 756 cells as deduced from hybridization analysis with individual HPV 18 restriction fragments as probes. Cellular DNA sequences are represented by zigzag lines. Because the viral integration sites are not precisely known, the virus–cell junctions are indicated by dashed lines. A restriction endonuclease map of prototype HPV 18 DNA[2] is presented above, indicating the cleavage sites for *Hin*cII (□), *Bam*HI (■) and *Eco*RI (●). Sizes of restriction fragments are given in kb. The 1.15-kb *Hin*cII fragment is drawn at both sites of the linearized HPV 18 DNA. The arrangement of open reading frames in HPV 6b DNA is given on top. The arrow denotes the possible direction of transcription in HeLa cells (see text). Modifications in restriction enzyme cleavage sites in the integrated HPV 18 sequences are not indicated. The existence of at least two different populations of integrated HPV 18 sequences in HeLa cells is not taken into consideration. The integrated HPV 18 sequences as shown may contain putative sequence rearrangements which would disturb the strict co-linearity with the prototype HPV 18 DNA.

Methods. *A*, Cells of the HeLa line, C4-1 line[16] and 756 line[17], all established from human cervical cancer biopsies, were grown in monolayer cultures in Eagle's minimum essential medium containing 10% fetal calf serum. Cellular DNA was prepared from the nuclei of cells which were used to isolate cytoplasmic RNA by incubation in 1% sarcosyl, 25 mM Tris-HCl *p*H 8.0, 8.3 mM EDTA *p*H 8.0, 100 μg ml^{-1} proteinase K for 1 h at 37 °C. The DNA was purified by repeated extractions with phenol and chloroform: isoamyl alcohol (24:1) and was precipitated by the addition of isopropanol. Cellular DNA (10 μg) was cleaved with *Bam*HI, separated on a 0.8% agarose gel and transferred to nitrocellulose filter[18]: HeLa (lane *a*), C4-1 (lane *b*), 756 (lane *c*), 100 pg cloned HPV 18 DNA digested with *Bam*HI and *Eco*RI (lane *d*, the fragment sizes are indicated). HPV 18 DNA was purified from pBR322 vector DNA by agarose gel electrophoresis and was labelled by nick-translation[19]. Subgenomic fragments were prepared by digestion of HPV 18 DNA with *Bam*HI and *Eco*RI and fractionation of the cleavage products in a 0.8% agarose gel. Three fragments were isolated from the gel: 2.4-kb *Bam*HI/*Eco*RI, 1.1-kb *Bam*HI and 4.4-kb *Eco*RI/*Bam*HI fragment. The latter was further cleaved with *Hin*cII to prepare the 1.15-, 1.4- and 1.8-kb fragments (see Fig. 1*b*). Hybridizations were performed in 50% formamide, 5×SSC for 2 days at 42 °C. Filters were washed at 68 °C for 3×30 min in 2×SSC, 0.1% SDS and were exposed to X-ray films (Kodak X-Omat XR5) for 7 days with intensifying screens. Subgenomic fragments of HPV 18 DNA used as labelled specific probes (see Fig. 2*b* for HeLa DNA) are indicated by arrows at the respective cellular bands which they recognized. ***B***, HeLa DNA 10 μg was cleaved with either *Bam*HI (lanes B) or *Bam*HI plus *Eco*RI (lanes BE) and separated on 0.8% agarose gels. HPV 18 restriction fragments used as nick-translated probes are indicated at the bottom. The bars indicate the λ*Hin*dIII size marker fragments (23,130, 9,419, 6,557, 4,371, 2,322 and 2,028 bp). The results of the hybridization experiments are further schematically summarized in Fig. 1*c*.

(Fig. 3, lanes *a*–*d*). Apart from the 1.15-kb *Hin*cII fragment, which gave a faint hybridization signal for the 5.5-kb RNA of C4-1, no other nick-translated fragments hybridized to any RNA. The 2.4-kb fragment contains sequences homologous to positions 120–2,340 of HPV 6b DNA, thus representing the early open reading frames E6, E7 and most of E1 (Fig. 1). The Northern analysis therefore showed that in all three cell lines HPV 18 transcription is restricted to sequences from this part of the early region (Fig. 1*d*). The HPV 18-positive RNAs were estimated to comprise 0.01–0.02% of total poly(A)$^+$ RNA in 756 and C4-1 cells and ~0.2% in HeLa cells.

The orientation of the HPV 18 transcripts was analysed initially by using the 3′-terminally labelled strands of the 0.7-kb *Xba*I/*Eco*RI fragment (located within the E1 open reading frame; Fig. 1*b*) as single-stranded probes for Northern blot hybridization with HeLa poly(A)$^+$ RNA. The different amounts of label incorporated into the *Xba*I and *Eco*RI fragment ends, respectively, enabled us to distinguish the two DNA strands and to predict their polarity (Fig. 4 legend). The DNA strand containing the labelled 3′ *Xba*I end hybridized to the 3.5-kb RNA of HeLa, whereas the complementary strand containing the labelled 3′ *Eco*RI end failed to give any hybridization signal (Fig. 4), indicating that transcription proceeds in the sense direction through the early HPV 18 genes. The 1.6-kb RNA did not hybridize to either probe, suggesting that it does not contain sequences from the 0.7-kb segment.

The large size of some of the HPV 18-containing transcripts suggested that transcription may run further into flanking cellular (or non-HPV 18) sequences. Therefore, cDNA libraries from the poly(A)$^+$ RNA of the HeLa, 756 and C4-1 cell lines were constructed and cDNA clones positive for hybridization with HPV 18 DNA isolated (E.S. and Zs. Schwarz-Sommer, to be published elsewhere). Of 18 cDNA clones from 756 cells, 7 hybridized with nick-translated total DNA from human embryonic lung cells, indicating that they contain sequences which are repeated severalfold in the human genome. Furthermore, the genomic *Bam*HI fragment of 756 DNA harbouring the junction between the transcribed E6–E1 region of HPV 18 and the flanking cellular sequences also contains sequences in the cellular part which hybridize to nick-translated DNA of human embryonic lung cells (W.M., unpublished result). Together, these data strongly suggest that the seven 756 cDNA clones were derived from composite transcripts containing both early HPV 18 and cellular sequences. In contrast, all 40 HeLa and C4-1

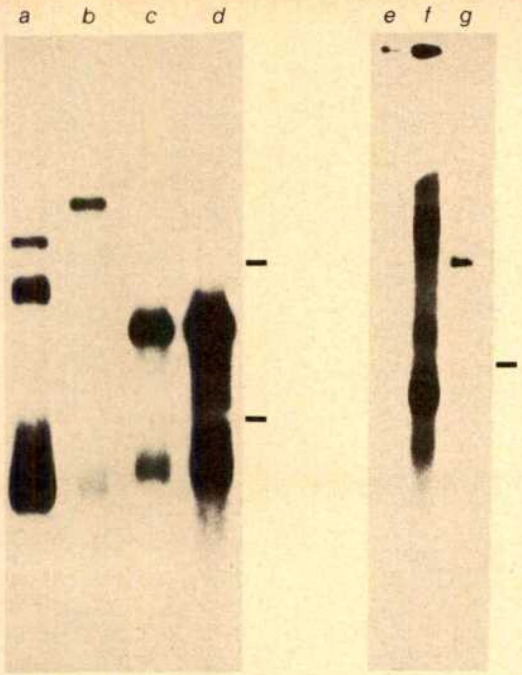

Fig. 3 Northern blot analysis of RNA from human cervical cancer cell lines (lanes *a*–*d*) and from cervical carcinoma biopsies (lanes *e*–*g*). Cytoplasmic RNA was prepared from tissue culture cells by lysis of cells in 0.6% NP40, 0.15 M NaCl, 10 mM Tris-HCl *p*H 7.4, 1 mM EDTA, pelleting of nuclei and repeated extractions of the supernatant with phenol–chloroform/isoamyl alcohol (24:1) as described elsewhere[20]. Poly(A)$^+$ RNA was isolated by oligo(dT)-cellulose chromatography[21]. Total RNA from tumour biopsies was prepared essentially as described elsewhere[10] followed by isolation of poly(A)$^+$ RNA. RNA was fractionated on 0.8% formaldehyde agarose gels[22] and transferred to nitrocellulose filters, using 2 μg C4-1 (lane *a*), 1 μg 756 (lane *b*) and 0.1 μg HeLa (lane *c*) poly(A)$^+$ RNA. In lane *d*, 10 μg total cytoplasmic RNA from HeLa cells was fractionated. The 2.4-kb *Bam*HI/*Eco*RI fragment of HPV 18 DNA (see Fig. 1*b*) was used as nick-translated probe. The bars indicate the positions of 18S (1,850 bp) and 28S (4,850 bp) ribosomal RNA used as size markers. In lanes *e*–*g*, 5 μg poly(A)$^+$ RNA from each tumour biopsy were fractionated. HPV 16 DNA was used as hybridization probe which was purified from the vector DNA before nick-translation. The bar indicates the position of the 2-kb β-actin RNA identified by hybridization of the same filter with a nick-translated β-actin probe[23]. Hybridizations were performed in 50% formamide, 5×SSC for 48 h at 42 °C. Filters were washed in 2×SSC, 0.1% SDS at 68 °C and exposed to X-ray films for 2 days (lanes *a*–*d*) or for 7 days (*e*–*g*) with intensifying screens.

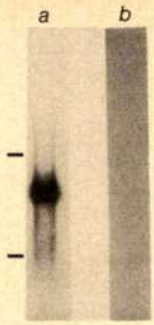

Fig. 4 Direction of HPV 18 transcription in HeLa cells. The 0.7-kb *Xba*I/*Eco*RI fragment of HPV 18 DNA (see Fig. 1*b*) was 3′-terminally labelled with DNA polymerase I (Klenow fragment) by incorporation of [α-^{32}P]dTTP. The DNA strands were separated in a 5% polyacrylamide gel in strand-separation conditions[15]. From the different amount of label incorporated (2 molecules TTP per *Eco*RI end and only 1 molecule per *Xba*I end), the more slowly migrating strand (1.2×10^6 c.p.m.) and the faster-migrating strand (2.3×10^6 c.p.m.) were deduced to contain the labelled 3′-*Xba*I end and 3′ *Eco*RI end, respectively. Northern blots with 1 μg HeLa poly(A)$^+$ RNA per slot were prepared and the filters were hybridized with the single-stranded DNA probes: lane *a*, slower-migrating strand labelled at the 3′ *Xba*I end; lane *b*, faster-migrating strand labelled at the 3′ *Eco*RI end. Autoradiography was for 15 days.

cDNA clones tested were negative in the hybridization with human embryonic lung cell DNA, indicating that they lack repeated cellular sequences.

Three cervical carcinoma biopsies examined were found to harbour HPV 16 DNA (and no HPV 18 DNA), but all differed in the amount of HPV 16 DNA present and in their *Bam*HI cleavage patterns (data not shown). Northern blot analysis using total HPV 16 DNA as probe revealed poly(A)$^+$ RNA species hybridizing with HPV 16 DNA in two of the samples (Fig. 3, lanes *e*-*g*). The RNAs transcribed varied greatly in amount and the major transcripts differed considerably in length. However, the small amount of DNA and RNA which could be isolated from the biopsies hampered further analysis.

The HPV 18-containing human cancer cell lines seem to differ from mouse cells transformed by bovine papillomavirus type 1 (BPV 1) and hamster tumours induced by BPV 1 in that the transcribed sequences are located in the E6–E7–E1 segment of the early region whereas the most abundant transcripts in BPV 1-transformed cells contain sequences from the end of the early region (E2, E4, E5)[9–11]. This part of the early region, however, is uncoupled from the upstream early sequences in 756 cells by integration of the HPV 18 DNA into the cellular genome and it is probably deleted in HeLa and C4-1 cells. Moreover, no transcripts from this region could be detected in 756 cells. Another difference is that the HPV 18 sequences are integrated into the host genome, a situation observed in most HPV 16- and HPV 18-positive cancer biopsies[2,24], whereas the BPV 1 genome persists mainly as an extrachromosomal episome (for review see ref. 12). In VX2 and VX7 transplantable carcinomas of domestic rabbits, however, DNA of the cottontail rabbit papillomavirus is integrated into the cellular DNA and the E6–E7 region is transcribed and spliced to the 3-terminal part of E2[13,14].

The transcription of specific early HPV 18 sequences in cervical cancer cell lines and the presence of HPV 16-positive poly(A)$^+$ RNA species in carcinoma biopsies further point to an active role of human papillomaviruses in genital cancer.

We thank Dr T. Bauknecht for providing us with cervical carcinoma biopsies, Dr M. Herlyn for the 756 line, Dr D. Gallwitz for cloned human pseudo-β-actin DNA, and B. Kürschner, B. Gewahl and M. Hotz for technical assistance. cDNA cloning was performed at the Max-Planck-Institut für Züchtungsforschung and E. S. thanks Drs Zs. Schwarz-Sommer and H. Sommer for advice in the cloning experiments. This work was supported by the Deutsche Forschungsgemeinschaft (SFB 31: Tumorentstehung und -entwicklung).

Human genes for U2 small nuclear RNA map to a major adenovirus 12 modification site on chromosome 17

Valerie Lindgren*, Manuel Ares Jr†, Alan M. Weiner† & Uta Francke*

Departments of *Human Genetics and †Molecular Biophysics and Biochemistry, Yale University, New Haven, Connecticut 06510, USA

U2 RNA is one of the abundant, highly conserved species of small nuclear RNA (snRNA) molecules implicated in RNA processing[1]. As is typical of mammalian snRNAs, human U1 and U2 are each encoded by a multigene family. In the human genome, defective copies of the genes (pseudogenes) far outnumber the authentic genes[2]. The majority or all of the 35 to 100 *bona fide* U1 genes[3–5] have at least 20 kilobases (kb) of nearly perfect 5′ and 3′ flanking homology in common with each other[4,6]; these U1 genes are clustered loosely in chromosome band 1p36 (refs 5, 7) with intergenic distances exceeding 44 kb. In contrast, the 10 to 20 U2 genes are clustered tightly in a virtually perfect tandem array which has a strict 6-kb repeating unit[8,9]. We report here the assignment, by *in situ* hybridization, of the U2 gene cluster to chromosome 17, bands q21–q22. Surprisingly, this region is one of three major adenovirus 12 modification sites which undergo chromosome decondensation ('uncoiling') in permissive human cells infected by highly oncogenic strains of adenovirus[10,11]. The two other major modification sites, 1p36 and 1q21, coincide with the locations of U1 genes[5,7] and class I U1 pseudogenes[12], respectively. We suggest that snRNA genes are the major targets of viral chromosome modification.

To map the U2 genes, we hybridized a U2 probe with the chromosomes of a normal female (Fig. 1*a–c*). In the 119 cells analysed, 164 (31.1%) of the total 528 silver grains were located over bands 17q12–q22, with a peak at q21. This result was confirmed by hybridizing the probe with the chromosomes of a normal male: in 39 cells, 34 (22.6%) of the total 168 grains lay over bands 17q12–q22. Figure 2 illustrates the combined data for chromosome 17 from the two experiments. Although there are many U2 pseudogenes in the human genome[2,13,14], no secondary sites of hybridization were detected in either experiment with normal human chromosomes (data not shown). However, most U2 pseudogenes are processed genes that contain only 33–82 bp of U2 sequence and lack flanking homology to the U2 genes[13]; *in situ* hybridization probably would not detect homologies of this length.

To delineate the region of assignment further, we hybridized the plasmid to cells carrying a human translocation chromosome. This chromosome, der(11), consists of the long arm of chromosome 17, from the middle of band q21 to the end of the long arm, translocated to the short arm of chromosome 11 [t(11; 17)(p15; q21)][15] (Fig. 3). Because cells from the human donor with the reciprocal translocation were no longer available, we used mouse–human hybrid cells retaining the der(11) chromosome under selective pressure[16]. The derivative chromosome was present at a frequency of 1.3 copies per cell. Of the 22 grains overlying this chromosome, 16 were localized over the junction region 11p15–17q22 (Figs 1*d*, 3). Thus, U2 genes are present in the region 17q21–q22.

The results obtained with the hybrid clone do not exclude the possibility that the U2 gene cluster was broken by the translocation in the parental human fibroblasts. The length of the U2 gene cluster (~100 kb), however, is small compared with that of a chromosome band (3,000–5,000 kb). Because the translocation breakpoint is near the middle of band 17q21, band 17q12 and the proximal portion of band q21 can reasonably be excluded as the site of the genes. In the normal lymphocytes a large proportion of the grains lay over band q21, with only a small percentage localized over q22. Therefore, the probable location of the genes is the distal half of q21.

The region 17q21–q22 containing the U2 genes is one of three major adenovirus type 12 modification sites[11]; productive infection of human cells causes these regions to appear 'uncoiled' and often to break[10]. Adenovirus types 2 and 5, which are not as highly oncogenic as type 12, also induce chromosomal gaps and breaks, but apparently at random sites[17]. Because the thymidine kinase (TK) gene maps near the modification site on chromosome 17 and adenovirus 12 infection stimulates TK production by a factor of 2–3 (ref. 18), McDougall[17] suggested that the localized alteration of chromosome structure might be related to virally induced transcription of specific host genes.

Previously, no genes had been correlated with the two other major modification sites on chromosome 1 in bands p36 and q21 (ref. 11). However, a minor modification site at 1q42 was localized immediately proximal to the 5S rRNA genes[19]. As shown in Fig. 4, the major modification site on the short arm of chromosome 1 coincides with the site of the U1 RNA genes in 1p36 (refs 5, 7). Further, the site in the long arm of chromosome 1, 1q21, is in the region 1q12–q22 to which we have assigned class I U1 RNA pseudogenes[12]. Pseudogenes of this

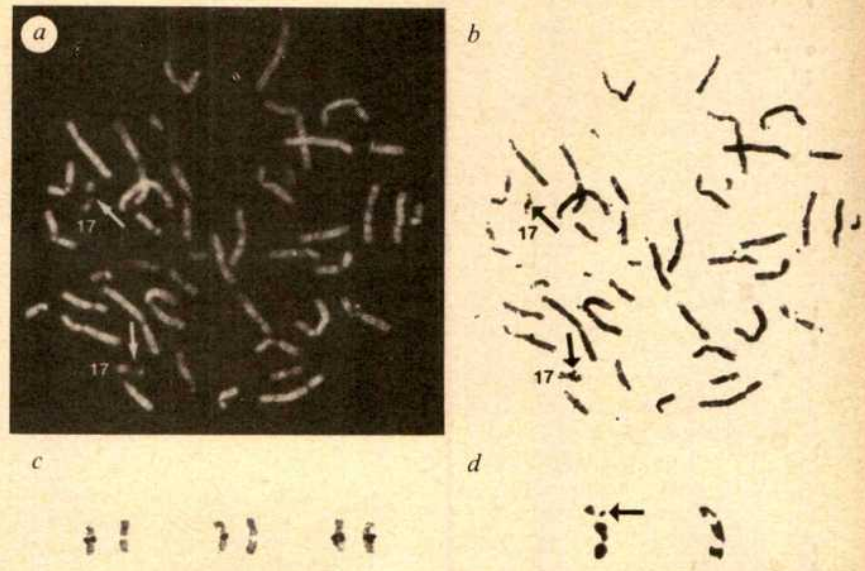

Fig. 1 Human metaphase chromosomes after *in situ* hybridization with the U2 probe. *a*, Representative chromosome spread from a methotrexate-synchronized culture of phytohaemagglutinin-stimulated lymphocytes[24], from a normal individual, stained with quinacrine mustard dihydrochloride[25,26]. Arrows indicate grains overlying the region 17q12–22. *b*, Cell shown in *a* after staining with 0.06% Wright stain. *c*, Pairs of chromosomes 17 from cells with grains overlying one or both homologues. *d*, der(11) chromosome, the result of the translocation t(11; 17)(p15; q21)[15], with typical labelling over the arm containing bands 17q21–qter (arrow). On the right, for comparison, is a trypsin-banded example of the chromosome. The U2 probe, pBR322 derivative pML2d with an 896-base pair (bp) insert containing the entire 188-bp U2 coding sequence, hybridizes only to the U2 array in Southern genomic blotting experiments (data not shown). The plasmid was labelled by nick-translation with three tritiated nucleotides (dATP, dCTP and dTTP) to a specific activity of 2.5×10^7 c.p.m. per μg of DNA. Hybridizations were carried out for ~16 h at 37 °C at a probe concentration of 25 ng ml^{-1} as described elsewhere[27]. Slides were coated with emulsion and developed after 5 days of exposure at 4 °C.

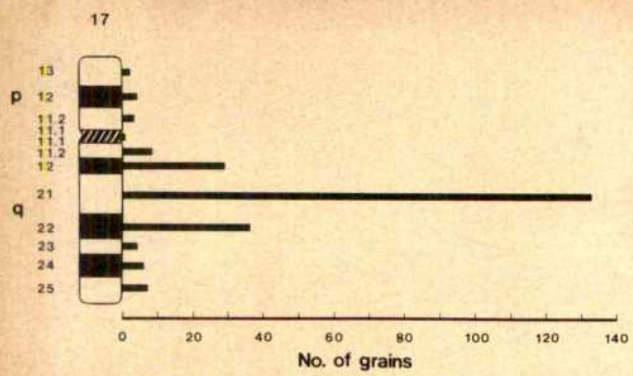

Fig. 2 Representation of chromosome 17, showing the distribution of grains after hybridization of the U2 probe with normal chromosomes from two human donors. Horizontal bars indicate the numbers of grains observed over the corresponding band in 158 metaphase spreads.

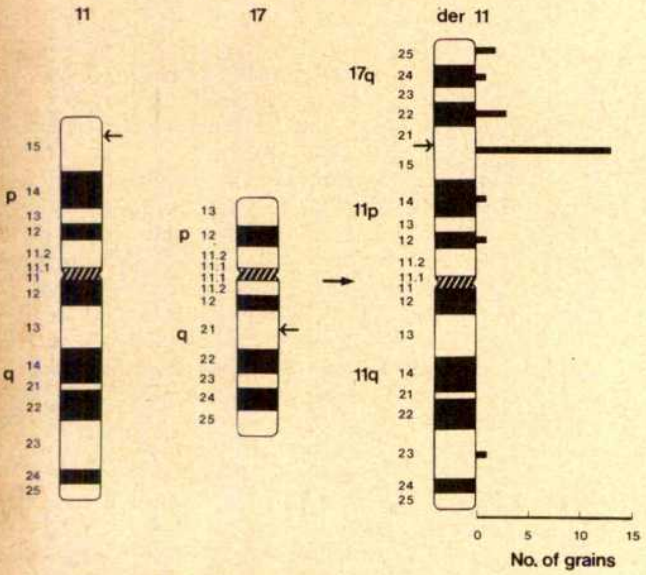

Fig. 3 *In situ* hybridization of the U2 probe with the der(11) chromosome in hybrid cells. Small arrows denote the breakpoints in bands 11p15 and 17q21 that led to the translocation t(11; 17)(p15; q21)[15] in the human parental fibroblasts. Hybrids between these fibroblasts and mouse thymidine kinase(TK)-deficient 3T3 cells were selected in hypoxanthine-aminopterin-thymidine medium to retain the der(11) chromosome, containing the region 17q21-qter, and/or the normal chromosome 17, both of which carry the human TK gene[16]. Bars next to the der(11) ideogram illustrate the numbers and positions of grains observed over 31 der(11) chromosomes in 24 hybrid cells. The peak of the grain distribution coincides with the lightly staining fusion band composed of 11p15 and 17q21.

class, unlike those of classes II and III, share extensive flanking homology with the true U1 genes[3,6]. All four well-characterized class I U1 pseudogenes that we have mapped to 1q12-q22 cross-react with the true U1 genes at 1p36 but with no additional chromosomal sites. Thus, most or all class I U1 pseudogenes map to the third modification site. As all three of the major adenovirus 12 modification sites contain snRNA genes or very closely related pseudogenes, and one of the minor sites is near the 5S rRNA genes, we propose that these highly transcribed genes are the primary targets of the viral modification.

Studies on the structure of active chromatin lead most naturally to the hypothesis that virally induced chromosomal unfolding reflects snRNA gene activation, although gene inactivation or localized DNA replication cannot be excluded. For example, the adenovirus E1a transforming gene product may

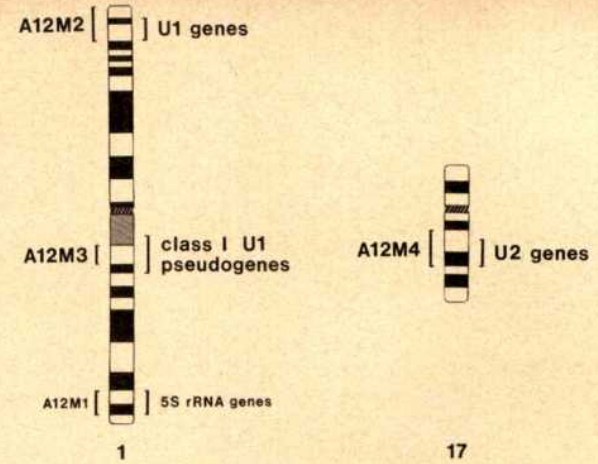

Fig. 4 Locations of human snRNA gene and pseudogene clusters correlate with the major adenovirus type 12 modification sites. As indicated by brackets, the three major viral modification sites, labelled A12M2, 3 and 4 (ref. 28), correspond exactly to the map positions of the U1 genes[5,7], class I U1 pseudogenes[12], and the U2 gene cluster, respectively. One of the minor modification sites, A12M1, is localized near the 5S rRNA genes[19].

activate the U1 and U2 genes in *trans*, as it does a variety of other endogenous[20] and exogenous[21,22] RNA polymerase II transcription units, as well as RNA polymerase III transcription units like the 5S RNA genes (A. J. Berk, personal communication). Alternatively, the E1a product may repress snRNA expression, as it does the expression of the class I major histocompatibility antigen in infected cells[23]. Class I U1 pseudogenes may be affected because they possess good flanking homology to the true U1 genes and may retain functional regulatory sequences in the DNA. An examination of the effects of viral infection on expression of host cell snRNA and of 5S rRNA may help to clarify the role of localized chromosomal uncoiling in the adenovirus life cycle.

We thank Christina Keller, Margaret Liao and Brigitte Foellmer for technical assistance. This work was supported by a James Hudson Brown-Alexander B. Coxe fellowship from the Yale School of Medicine (to V.L.) and NIH grants GM 09148 (to M.A.), GM 26105 (to U.F.) and GM 31335 (to A.M.W.).

Cyclic GMP to nicked DNA

This month's New on the Market selection includes a new cyclic GMP assay and a DNA nick-translation kit.

● An economically priced simple and convenient kit to nick-translate DNA in one hour has been introduced by Cooper-Biomedical. With this kit it is easy to obtain DNA labelled at 2×10^8 d.p.m. per microgram, making preparation of hybridization probes easy and inexpensive.
Circle No. 100 on Reader Service Card.

● Sepragel, new from Biotechnology Development Corporation, is a range of pre-cast polyacrylamide electrophoresis gel gradients in the popular 16 × 12 cm gel sizes. These thin 1.5-mm gels give a high resolving power and good reproducibility for autoradiography and Western blot techniques. Gels are supplied in two buffer systems (SDS and non-SDS) and four gradient ranges (3–27%; 10–20%; 3–12%; and 17–27%). For rapid evaluation inexpensive introductory kits are available containing a 16-page instruction manual.
Circle No. 101 on Reader Service Card.

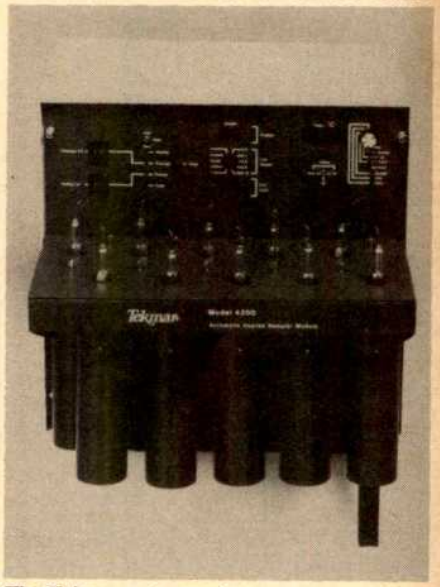
● Romicon, Inc. has developed a new membrane for the processing of high purity water (HPW) in the pharmaceutical industry. It is more economical than distillation and more reliable than reverse osmosis. Romicon's HPW membranes can withstand repeated cleaning with strong acids and strong bases, and can remove particulates, bacteria and other debris from water.
Circle No. 102 on Reader Service Card.

High purity water can be made using Romicon's new filter.

These notes are based on information provided by the manufacturers. For further details circle the appropriate numbers on the Reader Service Card bound inside the journal.

● The Eldex Chromat-a-trol is a microprocessor-based gradient and systems programmer that achieves precise control without the restrictions imposed by many dedicated systems. The Chromat-a-trol will generate binary gradients with most HPLC pumps, as well as control up to 24 external events. The large memory, and capacity to stack and cycle methods, make the Chromat-a-trol a versatile systems controller.
Circle No. 103 on Reader Service Card.

Hazard warnings from Lab Safety Supply.



● The recently introduced OSHA "Hazard Communication Standard and Right to Know" laws make it mandatory that, in the United States, a material safety data sheet be available for each hazardous substance in the workplace. Lab Safety Supply has developed a new ring binder to keep hazard information readily available and protected. The highly-visible binder is equipped with a set of index tabs, 50 sheet protectors, 50 material safety data sheet forms and a booklet on preparing and understanding the data sheets. Binders can also be customized with a company logo.
Circle No. 104 on Reader Service Card.

● A new line of threaded ultracentrifuge tubes and caps is available from Sarstedt, Inc. Available in six sizes, these thick-wall reusable polycarbonate or cellulose tubes feature moulded, precision threads and straight, constant internal diameter walls for easy removal of pellets. One-piece caps are anodized aluminium with sealing O-rings and a threaded hole to accommodate rotor cap tools for easy removal. Tubes can be spun at 40,000 to 50,000 r.p.m. depending on tube size and can be used in most Beckman, Kontron and Sorvall fixed-angle ultracentrifuge rotors.
Circle No. 105 on Reader Service Card.

● Mitsubishi's KF-05 microprocessor-controlled moisture meter displays and prints out moisture levels in gases, liquids, and solids over a range of 0.01% (100 p.p.m.) to 100%. Using the Karl Fischer titration method, it automatically titrates to a fixed end point (selectable from 5 to 120 s), and calculates concentration according to one of 10 stored formulas.
Circle No. 106 on Reader Service Card.

● The Spectroflow 783 absorbance detector, manufactured by Kratos Analytical, combines high sensitivity, minimal drift and maximum versatility in a compact package that is not only programmable but is also computer-compatible. Flowcells are self-aligning and can be easily changed to allow successful operation in microbore LC, conventional HPLC, fast LC, semi-prep LC, open column LC and low pressure LC.
Circle No. 107 on Reader Service Card.

● Biomedical Technologies, Inc. has developed a sensitive cyclic GMP radioimmunoassay kit. Levels of cyclic GMP can be accurately measured from urine, plasma, tissue, cell culture and other sources. The sensitivity of the assay is 1.10 picomoles per tube and 0.005 picomoles per tube for acetylated sample. The kit makes use of a highly specific preconjugated cyclic GMP antibody and an iodine-125 labelled tracer. The protocol includes only three pipetting steps and one incubation, and generates a visible precipitate.
Circle No. 108 on Reader Service Card.

The Tekmar autosampler.

● The Tekmar 4200 is a fully automatic ten position autosampler system with individually heated samples designed for use with the Model 4000 Dynamic headspace concentrator. The Model 4000 is a fully automatic purge and trap system that allows for the concentration and desorption of volatile organics for GC analysis. Interfaced with the Model 4000 concentrator, the 4200 permits automatic analysis of as many as ten samples with a sample temperature range of ambient to 173°C.

Market signals and subject choice

from Richard Pearson

The involvement of prospective employers in sponsoring students in higher education can lead to improvement in courses in general, as well as benefiting individuals.

IN the 1980s, teachers and educationalists are expected to consider 'market signals' when planning course provision and curricula. Likewise students entering higher education are expected to adjust their subject preferences by noting changes in relative salaries, career prospects and unemployment rates. The hoped-for outcome is that educational output becomes more closely aligned to economic and labour market needs. As well as offering improved career prospects and higher salaries, employers are increasingly using sponsorship of students in higher education as a means of attracting those with scarce skills (*Nature* **307**, 488; 1984). To aid this process, in 1984 the UK Department of Education and Science increased the amount a student could receive from an employer by way of a term-time bursary from £915 to £1,600 a year, with the secretary of state commenting "I am sure that these increased sponsorship levels will help to attract able students to pursue courses of great importance both to them, to employers, and to the economy..."

For individual employers, the prime motive in sponsoring undergraduates is to meet their own recruitment needs. They are now spending over £10 million each year on such activities. In 1984, one in four final-year engineering undergraduates was being sponsored, while the number of final-year electronics graduates receiving sponsorship increased by over 70 per cent in the past five years. A report shortly to be published by the Institute of Manpower Studies (see Table 1) examines the extent to which this market signal is also affecting the subject choices of those entering higher education and thus expanding the overall supply of students in poorly patronized subjects.

There was clear evidence that the number of engineering students wanting sponsorship was far greater than the number of sponsorship places available. Given the real and perceived benefits of employer sponsorship — guaranteed industrial training, extra income, close links with an employer, and the probable offer of a job on graduation — this was not surprising (Table 1). The offer of sponsorship affected one in four students' choice of course and institution (Table 2). The biggest impact was on the choice of institution, although a significant minority switched to sandwich courses as a result of sponsorship. Of those switching subject, for a few the shift was fairly dramatic, for example from biochemistry to mechanical engineering, but for many it meant a more limited adjustment.

Table 1 Students' views on the benefits of sponsorship

Extra money	55%
Practical experience	41%
Future job prospects	29%
Vacation job	24%
Better training	14%
Other	5%

Percentages are proportions of sponsored students only. These data, and data in Table 2, are from "Employers Sponsorship of Undergraduate Engineers, by A. Gordon, R. Hutt & R. Pearson (Gower, Aldershot, in the press).

The impact on students depended to some extent on the way in which the employers' lists of preferred courses were drawn up. The criteria for inclusion were not only the perceived relevance or reputation of the course, but also the apparent status of the institution, the kind of student believed to be attracted to and accepted by it, the historical experience of senior managers and the recent experience of graduate recruitment personnel. Only a minority of employers included polytechnics on their preferred list.

Sponsorship can however cause difficulties for those not directly involved. Thus non-sponsored students on sandwich courses were finding it increasingly difficult to find training placements. Some teaching staff were concerned that links with a single employer might also make a student's industrial experience excessively narrow and in some cases unduly influence course content and pattern. The view was also expressed that because sponsorship focuses student and employer attention on certain, usually well known, institutions and courses, it can inhibit the development of new courses.

Because of sponsorship arrangements, each year a significant proportion of engineering graduates move directly into jobs with their sponsoring employer and effectively do not become job seekers in the annual graduate recruitment round. As a result, the number of newly qualified graduates actively seeking jobs in the labour market on graduation is considerably lower than the number graduating each year. Thus in 1983, some 500 or more newly graduating electrical/electronics engineers took jobs with their sponsoring employer while a further 600 to 800 chose to go on to research or further training or take jobs outside engineering. This meant that employers seeking to fill direct-entry appointments were recruiting from a pool of active job-seekers totalling some 2,000 rather than 3,100 newly graduating electrical/electronics engineers.

The sponsored graduates withdrawn from the open market in this way were not evenly distributed. They tended to be among the most highly qualified young engineers in terms of course entry qualifications, and were frequently concentrated in some of the most industrially oriented and often more prestigious departments and institutions. They had also often received relevant industrial training. Non-sponsoring employers seeking to recruit from these courses, and wanting a spread of ability and educational background in their new graduate recruits, will therefore have had increased difficulties.

Table 2 Influence of sponsorship on students' choices

Subject choice	14%
Type of course	25%
Institution	22%

Percentages refer to sponsored students only.

Overall it is clear that the availability of sponsorship has led directly to some students switching subjects and courses, a significant proportion in the case of production engineering, and acted as a positive signal to potential students about the subjects and courses employers value most. Sponsorship thus serves to increase, albeit by a small amount, the pool of students seeking to study in disciplines of the highest relevance to employers.

The content and pattern of degree courses is also being affected through the involvement of sponsoring employers, increasing their relevance to that group of employers. If these are also the most far-sighted and thoughtful employers in relation to engineering education, then the industry at large can be expected to benefit. However, sponsorship has most relevance and impact on market share, and on the quality of graduates recruited, aiding primarily the sponsoring employer and those directly involved, and has less impact on market size and the overall pool of engineering talent in the economy. □

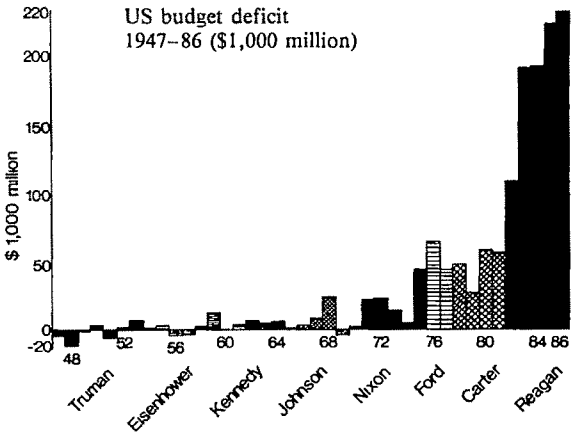
NATURE VOL 314 14 MARCH 1985

How not to fix the farm economy

President Reagan hopes the deficit will persuade Congress that farm programmes cannot be afforded. But a free market and exports will not cure all ills.



IRONY abounded last week as President Reagan vetoed legislation passed by Congress — with the help of his own Republican Senate — to give farmers emergency credit assistance. Reagan told Congress "someone must stand up to those who would say, 'here's the key to the Treasury — just take as many of those hard-earned tax dollars as you want' ".

For a President who four years ago handed those keys to Secretary of Defense Caspar Weinberger and has yet to ask for them back despite $200,000 million-a-year deficits, it was an interesting statement. Amid rhetoric that refers to that unprecedented deficit as some sort of natural phenomenon, it is perhaps easy to forget that it is in fact the direct result of the Reagan tax cuts and defence build-up. A glance at the accompanying graph, prepared by the non-partisan Congressional Budget Office, should be enough to set the record straight.

As for farm credit assistance, Reagan blamed the current troubles on "a generation of failed policies that drove down farm prices and drove up the costs of their land, seed and equipment", a statement that borders on a *non sequitur*, but which presumably reflects the President's instinctive dislike for anything that can be traced to Franklin Roosevelt's New Deal, rather than any precise statement of cause and effect. If the current credit crisis can be traced to anything, it is surely the expansionary policy begun under the Nixon Administration in which farmers were encouraged to plant "fencerow to fencerow". Farmers expanded; rural banks then pressed farmers to take full advantage of rising land values to borrow to the hilt. Farmers, straddled with high interest rates and coming out of several consecutive years of losses, cannot now get operating loans, and rural banks, having made questionable loans in the 1970s, are faced with insolvency; but the crisis cannot be blamed on a "generation" of government intervention — rather, the blame is with an ill-thought-out burst of *laissez-faire* enthusiasm under Nixon that Reagan is repeating under the rubric of a "market-oriented" policy. The lesson of the 1920s, when *laissez faire* reigned, was that overpopulation is a chronic, recurrent disease in agriculture. Then, as now, the salvation of US farmers was supposed to be exports. The lesson has not apparently been learned that the world does not want to be fed by the United States, except in dire emergency.

It is tempting to view the current farm crisis as the inevitable consequence of an economy undergoing "restructuring"; the end result, in this happy view, is a leaner, more efficient economy. That is the view of David Stockman, director of the Office of Management and Budget, at least, That view is reinforced unwittingly by those proponents of assistance who say the government must help to preserve the "way of life" of the family farmer. An uncritical look at statistics also suggests that small farms are inefficient and might well vanish. But this is a pitfall. It is necessary to understand that the statistics call anything a "farm" that has a annual output of agricultural product worth $1,000. That definition pulls in thousands of farms that are really not; some 70 per cent of all "farms" have sales of less than $40,000 per year, and these are about evenly divided between those owned by people who work elsewhere and farm mainly for amusement and those owned by older farmers who paid off their mortgages long ago. They are inefficient and produce a negligible amount of the nation's food. They are not the people in question.

Those who are calling for help now are the full-time family farmers, who, according to a 1981 Department of Agriculture study, are virtually as efficient as the very largest farms. (The study found that almost all economies of scale are attained by farms of about 300 acres, roughly the national average.) Expansion, and the inevitable elimination of some operators, occurs not because the smallest are inefficient, but because the smallest simply cannot produce enough income to support a family. Society does not gain from further expansion and concentration of production in fewer hands among this group. Yet that is the inevitable consequence of policies that foster overproduction, depressed prices and the substitution of capital for labour without any gains in overall cost efficiency.

There are really only two points which argue for continued government intervention. One is that society has a legitimate interest in preserving diversity, both geographical and economic, in the farm economy, so long as efficiency is not harmed. Second, again as the 1920s should have taught us, is that periodic booms and busts are harmful and inevitable in an unregulated market made up of producers with a high capital investment who sell what economists call perfectly competitive goods. Farmers are price takers; they must accept whatever the wholesaler offers. And even when those prices fail to meet costs, farmers have little choice but to continue producing (exacerbating the overproduction that depressed prices in the first place) in the hope of making good on their sizeable capital investment. General Motors can stop buying parts when demand falls; Sears can stock new items in its warehouses; but a farmer can do only one thing with a milking parlour.

The Reagan Administration is correct in saying that the current mess of contradictory farm programme has to go. A rational public policy aimed at intervening in the farm economy to level out the peaks and troughs need not cost a sum that approximates total net farm income (as it has in recent years). It certainly does not need programmes that encourage production.

First, instead of throwing up its arms and shouting "compete", the government could limit subsidies to the first increment of production per farm; the current system of "target prices", which operates at the margin, is an out-and-out production incentive that has no place in a rational solution. The second, more drastic, step is to be tougher in tying *all* federal assistance to a farmer's acceptance of rigid production limits. Farmers resist this, as a

matter of pride and to hold to their cherished image of themselves as rugged individualists. The New Deal programmes that have been inherited were attempts to plan the farm economy by doing everything but; it is time to drop the pretence and save a few billion dollars in the process.

Agricultural research, which is a metaphor for the sickness of overall farm policy, has also suffered from short-sightedness. Research programmes arise from the mists to appease some local constituency or deal with some emergency. Painfully absent has been a long-term commitment to solving fundamental problems. A genuine investment in basic research in plant molecular biology — which means considerably more than the still-token effort to establish a peer-reviewed grant mechanism for agricultural research — could pay off in lower input costs to farmers by cutting their dependence on energy-linked tillage, fertilization, irrigation and pest-control costs. That in turn could do much to reduce the expansionary pressures on farmers that are now answered by taking out more and more loans and overproducing.

Imbalanced budgets

Next week's British budget could be decisive for the future of British industry and innovation.

CAN governments do anything at all to revitalize an economy fallen on bad times? In a blend of disappointment and despair, this is likely to be the Britsh government's unspoken question about its revenue budget for the year beginning 1 April, due next week. For outwardly the government should now be basking in the rewards of six years of virtue. Learning from the mistakes of its predecessors since 1964, but also for doctrinal reasons, the present government has avoided, almost, direct intervention in the pattern of industry. Consistently it has been saying that governments can hope only to create the climate in which economic growth and thus prosperity will emerge. But eschewing direct intervention, governments must fall back largely on fiscal measures, whence the importance of next week's budget. The worry for the British and their government is that six years of almost consistent budget-management have so far produced only one tangible success — the inflation rate is a modest five per cent a year. Otherwise, unemployment continues to grow while the slow growth of the Gross National Product in the past few years consists largely of the expansion of service industries. Manufacturing industry (apart from oil) is still producing less than in 1979. And now interest rates are higher, and sterling lower, than ever before.

What has gone wrong? Why has so much effort been so poorly rewarded? From the outset, one of the government's key objectives has been to reduce the proportion of the national income spent by local and central governments, in the twin belief that the proportion has become too high and that, if the level of taxation were reduced, people would have more to spend in ways that would stimulate the economy. More recently, the same British government has been saying that direct taxation (on income) should be replaced by indirect taxation (on spending) because people could then choose investment rather than consumption.

Three things have caught the British government napping. First, public spending has remained high as a proportion of the total because of the growing social costs of unemployment and longevity, but also because spending on essential services such as education is so meagre that it cannot easily be cut. Second, when people have extra money because they pay less tax, they (or the financial institutions that hold their savings) are as likely to invest in industry elsewhere as in Britain. That is why there is something in the view of those economists who argue that restrains on capital outflows would bring immediate prosperity. (The snag is that the short-term would be very short.) Third, the government's actions have not been nearly as consistent as its rhetoric. Last month's sterling crisis seems to have been partly triggered by a belief that the government was allowing the money supply to grow in a way contrived not to show up in the accepted monetary statistic—but can it make sense to spend at least £10,000 million to replace Polaris nuclear submarines by Tridents at a time like this? (An Anglo-French accommodation on nuclear weapons would be cheaper and militarily prudent.)

Signs that the British government is beginning to lose its composure are, in the circumstances, inevitable but significant. With the sterling crisis, last month was replete with signs of fraying nerves. Even more remarkable was an attack delivered last Friday by Mr Nicholas Edwards, Secretary of State for Wales, on the financial institutions of the City of London. Mr Edwards accused them of "prejudice, ignorance and a striking lack of awareness" of what is happening in modern industry. He singled out an electrical and defence contractor, the General Electric Co PLC, for having accumulated large amounts of cash (in excess of £1,500 million) and for turning itself "into an investment bank" rather than investing in innovation. But what else can Mr Edwards expect, when his own government is prepared to offer people a rate of interest as much as ten per cent above the inflation rate, and when the rewards of innovation are unlikely to be as great?

That is the clue to the fiscal part of the solution to the problem of encouraging reinvestment in British enterprise. British interest rates are at present high not merely because they are tied to interest rates in the United States but because of the money mismanagement rumbled a month ago. The way to bring them down, and to cut the inflation rate, is further to reduce public spending. Tax cuts would work in the same direction but less quickly. The government's difficulty is that it has cut most things to the bone already, so that there is little scope for further manouevre. Sooner or later it will have to bite the defence bullet, and the sooner the better. Certainly there is little hope that productive investment can be stimulated by devices such as the ill-starred Business Expansion Scheme, which offers exemption from income tax for five-year investments in new business, and which seems chiefly to have stimulated property development. The moral, for those who like their fiscal policies to be clean and tidy (like the present government) are that a belief that the market knows best is incompatible with attempts to rig it. The moral for those who say that Britain is good at invention but poor at exploitation is that the explanation may lie in fiscal mismanagement. □

Polish normalcy?

Is the Polish government serious in saying it wants normal relations with the outside world?

THE account of Polish science by Vera Rich on page 123 says nothing of the circumstances in which the information was gathered. Ms Rich left London for Warsaw three weeks ago, on a visa provided by the Polish Embassy in London. The visa was due to expire at midnight on Tuesday, 26 February. Protesting in London that she planned to return on a charter flight only on the following day, 27 February, Ms Rich was told that there would be no difficulty if she left on the first flight that day.

On the morning of 27 February at Warsaw airport, the first flight was delayed for several hours, until 11 a.m. On exit, Ms Rich was told that her visa was not in order, she was stripped and searched, a number of documents and audio-tapes were confiscated and Ms Rich was bundled into the waiting aircraft. She returned to London in great distress, humiliated and shocked.

The Polish government is understandably ambivalent towards journalists, especially those from abroad. It rightly regards a reasonable trickle of such people as a proof that normalcy has returned, but it cannot apparently stomach, or even understand, journalists' inevitable curiosity about the events of the past four years. Not that Ms Rich's too-brief visit to Warsaw last month was in any way subversive — most of her meetings with officials were arranged under government auspices anyway. The Polish Embassy in London has not yet replied to a request for an explanation of why Ms Rich was bundled out of Warsaw in such an outrageous fashion. This note is meant to jog the embassy's memory. The explanation, if forthcoming, will of course be published. □

Nuclear winter

Pentagon says yes, it may happen, but "so what?"

IN its first official statement on "nuclear winter", the Department of Defense (DoD) has acknowledged the possibility of severe climatic change following a major nuclear war. But the DoD statement, which comes in the form of a report ordered by Congress*, asserts that the only policy implication is to affirm current US strategic doctrine on deterrence, arms control and Star Wars missile defence.

The DoD report echoes an earlier study issued by the National Academy of Sciences last December in its criticism of the large uncertainties in published estimates of the climatic effects of nuclear war. "At this time, for a postulated nuclear attack and for a specific point on the earth", the DoD report says, "we cannot predict quantitatively the materials that may be injected into the atmosphere, or how they will react there . . . . we do not expect that reliable results will be rapidly forthcoming."

DoD specifically criticizes uncertainties in the results of the study by Turco *et al.* (*Science* **222**, 1283; 1983). It says the estimate of the amount of smoke that would be produced in fires ignited by nuclear blasts was the result of combining a large number of poorly-known variables; "in actuality, the same yield weapon could produce vastly different amounts of smoke over different target areas and under different meterological conditions", DoD says.

A preliminary DoD assessment of 3,500 "hypothetical" non-urban target locations concludes that smoke production would be 30 times less than the Turco *et al.* assumption for July and almost 300 times less for January**. The DoD report also suggests that the results may have improperly shifted the focus from dust to smoke; if smoke production has been overestimated, and if one assumes a war scenario in which, for example, ground-burst attacks on missile silos predominate, producing a lot of dust, the effects of dust may outweigh those of smoke.

The DoD report also claims that initial results of three-dimensional models constructed by DoD and National Center for Atmospheric Research scientists show that scavenging of smoke and dust from the atmosphere may be "substantial".

DoD is spending $1.5 million on nuclear winter research this year and has requested $2.5 million for next year. An additional $2 million per year is coming from the Department of Energy.

But whatever the outcome of these studies, DoD is already suggesting that they will have no effect on US strategic policy. DoD claims credit in the report for having already adopted policies designed to limit both the extent of nuclear war and its atmospheric consequences. It claims that US policy is to avoid urban population centres in its targeting plans, a policy that would also limit bomb-ignited fires.

Significantly, DoD also uses the opportunity to push President Reagan's Star Wars plans, noting that even "single-layer defense" — perhaps a reference to a terminal site defence, the one star wars component that may be possible with existing technology — "may provide a greater mitigating effect on atmospheric consequences than could result from any level of reduction likely to be accepted by the USSR in the near term".

The report dismisses the argument that the Soviets would respond to a US anti-missile defence simply by increasing their offensive forces, claiming that since the signing of the anti-ballistic missile treaty in 1972, the Soviets have increased their forces fourfold. The report does not mention the US decision to arm its intercontinental ballistic missiles with multiple warheads during that period.

The clincher, as far as the Pentagon is concerned, is that even if the United States becomes convinced of the reality of the nuclear winter, "we cannot be confident that the Soviets would expect such effects to occur as a result of all possible Soviet attacks".

The DoD report claims that the Soviets have performed no independent calculation on climatic effects of nuclear war and in fact "show no evidence of regarding the whole matter as anything more than an opportunity for propaganda".

ASATs

US Air Force slows the pace

Washington

ALTHOUGH the congressional ban on the further testing of the US anti-satellite weapon (ASAT) expired last week, new tests have been postponed at least until June. Technical problems are partly responsible for the delay, but diplomatic concern about the Geneva arms control talks, due to open next week, may also have been influential.

The Air Force officially refuses to discuss the technical problems or the testing schedule of ASAT. But administration officials last week quietly spread the word about the technical delays. And according to *Commerce Business Daily* of 21 December 1984, the Air Force has asked for bids on a contract for the redesign of the ASAT's "maneuvering propulsion package", a group of 57 miniature solid-fuel rockets that steer the 12-inch ASAT projectile into its target.

The contract announcement mentions contamination from motor exhaust as one problem to be corrected. According to John Pike, a space-weapons expert with the Federation of American Scientists, contamination of infrared sensors has been a "canonical problem" with this type of weapon, going back to prototypes developed for ballistic-missile defence two decades ago. Infrared sensors are used to pick up the heat radiated by the target satellite and so guide the projectile, technically called the "miniature homing vehicle". The projectile carries no explosives, but disables the satellite simply by colliding with it.

So far, the Air Force has tested ASAT only by shooting at a point in space. Live targets have not yet been used. (According to some reports, for the "point in space" test last November, ASAT's infrared sensors were locked on a star or the planet Jupiter.)

Although the congressional ban on testing against live targets has now expired, the administration would still be required to send a lengthy certification to Congress before such a test could proceed. When the time comes, ASAT opponents say, the administration will have a difficult time completing that procedure with a straight face. Certification will require a finding that the test is necessary to avert "irrevocable harm" to national security, that the United States is trying to negotiate limitations of ASATs, that the test would not irreversibly harm prospects for negotiations and that it is consistent with the anti-ballistic missile treaty.

Representative George Brown (Democrat, California), one of the sponsors of the congressional restraints on ASAT testing and one of 102 congressmen who signed a letter to President Reagan last week urging a continuation of the moratorium, has suggested that the technical problems may be a convenient refuge for an administration that wants to keep up a tough image while not directly jeopardizing the Geneva talks. And Pike said, "I assume that, if they thought the safety of the republic was in jeopardy, they'd be working overtime [to correct the problems] but they've adopted a leisurely schedule".

A middle course that the Air Force may be contemplating is a second test against a point in space in June or July, which would not require the certification.

US space science

Manned flight to Mars?

Washington

ATHOUGH the National Aeronautics and Space Administration (NASA) is officially keeping its distance, a dedicated group of space scientists within and without the agency is busily hatching plots for a manned space flight to Mars. The so-called "Mars Underground" has held several conferences to discuss ideas for the mission, which, members of this loose network of enthusiasts say, could be done for as little as $17,000 million, and largely with

technology already available or being developed for NASA's space station.

The National Space Institute, a group of space buffs that sponsored two of the conferences, has even taken to distributing "Mars Underground" lapel buttons to be "quickly flashed" at first sight of the NASA administrator, senators and congressmen.

The rise of the Mars underground has highlighted a growing rift between those who favour continued unmanned exploration of the planets — mainly planetary scientists concerned about getting the most data per dollar — and those pressing for a project that would rekindle the "thrill of exploration" that was the main dividend of the Apollo flights to the Moon. Carl Sagan has recently been trying to bridge the gap, conceding that a manned mission is not justifiable on a scientific basis alone, but urging it nonetheless in the form of a joint US-Soviet venture "on behalf of the entire human species".

NASA's current plans for Mars are limited to the unmanned Mars Geoscience/Climatology Orbiter, scheduled for launch in 1990. Since the 1975 Viking 1 and 2 Mars landers, which raised many questions about the Martian surface, planetary scientists have been talking about follow-up missions involving a surface rover, a remotely-piloted vehicle and a return of a surface sample to the Earth.

To the extent that NASA is giving official attention to a manned Mars flight, it is in the context of advanced planning for the space station. Jesco von Puttkamer, NASA's programme manager for long-range studies — an office sometimes derisively described as NASA's division of daydreaming — says that a Mars flight is just one of five general categories of projects that an advanced space station could make possible; the others are low-earth-orbit instruments, commercial development of geosynchronous orbit, Solar System exploration with unmanned probes and establishment of a permanent lunar base. A space station would be a necessary jumping-off point for a Mars mission because of the sheer mass involved. Puttkamer says that a bare minimum weight for a Mars craft would be 2 million pounds; the huge Saturn V rocket built to launch Apollo to the Moon had a capacity of only 250,000 pounds. The space shuttle carries 65,000 pounds. Thus, assembly in Earth orbit is a necessity.

Puttkamer estimates the cost of the first Mars flight at $50,000-65,000 million; even that figure assumes a larger shuttle and an advanced space station would already be available. And because the Earth and Mars are in a favourable orientation for a transit only every two years, a one-shot flight makes little sense. Nobody knows how much a continuing programme of Mars flights, including establishment of a Mars base, would eventually cost.

The more enthusiastic enthusiasts, such as the Planetary Society, put the costs much lower ($17,000 million) and argue that new technology (such as aerobraking — using the atmospheres of Mars and the Earth to slow the craft down, instead of retrorockets) could cut fuel demand — and thus weight — considerably.

Some have also tried to raise the familiar Red Menace (which was good enough to get a man to the Moon) as a reason for pressing ahead. But according to a Congressional Research Service study by Marcia Smith, the Soviet capability argues against a serious effort on their part to put a man on Mars. The Soviets are apparently planning to send an unmanned probe to Mars's moon Phobos in 1986. But despite continued interest in Mars and a growing expertise in long-duration space flight, Soviet space hardware continues to be plagued with low reliability. Only one of the eight Soviet Mars probes has been an unequivocal success; the rest have missed the planet, crashed or failed to return data. And the Soviets have yet to try putting a man on the Moon. **Stephen Budiansky**

Biotechnology

Agrigenetics forced to merge

Washington

THE acquisition earlier this year of Agrigenetics by Lubrizol Corporation may herald a new trend in the biotechnology industry. Things have come a long way since the heady days of summer 1983, when it seemed that any company offering expertise in the new technology could do no wrong in the eyes of investors. By early 1984, public offerings were getting a much cooler reception, making difficulties for some companies seeking development capital. Agrigenetics, based in Boulder, Colorado, had seemed one of the industry's brightest hopes, having an impressive array of research expertise. But a combination of high interest rates and a depressed agricultural products market, together with the decline of the high-technology securities market, eventually forced it to seek a merger with a much larger company.

Lubrizol is saying very little about its business plans, but does not intend to alter the direction of Agrigenetics' research, which may even be augmented. But there must also be some doubt whether Lubrizol, as sole owner, will want to renew the limited partnership deal it struck with Oppenheimers of New York in 1981 and which expires in 1986. That programme, which supports research worth $11 million a year in 24 universities across the country, would be missed by many.

Analysts are cautious about generalizing too much from the Agrigenetics experience, since its business strategy was unusual from the start. Under chairman and founder, David Padwa, the company acquired seed companies to form a distribution network at the same time as expanding its research. Reliance on the agricultural products market may have increased its vulnerability with US agriculture in the doldrums. The research arm was spending $19 million a year principally on developing new crop varieties by applying new techniques such as the microinjection of DNA into plant cells, the use of Ti plasmids and the exploitation of transposable elements. By having a distribution network already in place, the company hoped be able to steal a march on competitors when products of the new technology eventually reached the market.

Things began to go wrong in November 1983, when the company decided to abandon a public share offering because of the deteriorating market. Looking instead at merger possibilities, Agrigenetics found Lubrizol, a manufacturer of special oils and oil additives, a likely mate. The company already owns 15 per cent of Genentech Inc., regarded by many as the Rolls-Royce of the biotechnology industry, and was seeking ways of using genetic engineering technology to produce improved vegetable oils.

Outstanding Agrigenetics shares were exchanged for 2.1 million Lubrizol shares worth $48 million, and in addition Lubrizol took on Agrigenetics' debt of $60 million. In the circumstances, Agrigenetics shareholders could have done much worse. Padwa resigned as chairman last month, but denies differences of opinion with the new owners over strategy, and may continue to serve occasionally as a consultant. **Tim Beardsley**

Poland

New directions for science

NEXT October, a grand "Congress of Polish Science" will be convened in Warsaw. The initiative for the Congress came from the government and party authorities, not from the scientists, most of whom seem to know little, so far, of the purpose of the proposed gathering. It seems, however, to be intended as a working meeting, not as a demonstration to the outside world that all is well with Polish science. For, according to Dr Ignacy Malecki, a leading member of the Polish Academy of Sciences, no foreign visitors will be invited. (Until his recent retirement, Dr Malecki regularly represented Polish science at the quasi-diplomatic level of ICSU and similar meetings.)

This does not mean that Polish science is going isolationist but rather that the congress, which, Dr Malecki hinted, will include a major session on technology and innovation, represents a determined effort to put science on a new path. For the present system of research support, based on a complex hierarcy of "problems" from the "governmental" down to the "branch" level, is in disarray and is expected to be phased out at the end of this year, when the current five-year plan comes to an end. Last December, the former Ministry of Science, Higher Education and Technology lost its responsibility for technological research and innovation, which was handed over to a new State Committee for Technical Progress that will be specially empowered to direct research funding to those areas likely to provide a short-term economic pay-off.

Even more significantly, science funding for the next five-year plan will give priority to fields such as computer science, electronics and biotechnology that were judged to be of particular contemporary significance by the recent Comecon summit. The support will be generous by Polish standards; in the case of biotechnology a sum of 15,000 million zloty (£100 million) has been mentioned, although some of this, at least, must be made available in hard currency, if even these leading areas are not to suffer from the endemic problem of contemporary Polish science — a lack of funds to purchase from the West journals, reagents and spare parts and replacements for ageing equipment.

These announcements have been received by the Polish scientific community with mixed feelings. The old system of funding by "problems" was universally unpopular. It caused considerable administrative difficulties whenever an institute wanted to buy some standard equipment, say a microscope, to be used by several teams working on different "problems", and ate into the time of the unfortunate members and employees of the Academy of Science who had to coordinate the efforts of scientists working on the same "problems" in institutes scattered all over Poland. The large sector of "branch" research institutes, belonging neither to the academy nor the universities, is in considerable confusion, and few would question, in principle, the need for new legislation to cover that sector. Even the increased emphasis on practical applications is viewed by many as an unfortunate necessity of Poland's continuing economic crisis.

What the scientists find less acceptable, however, is that decision-making on priority investment in Polish science has, effectively, been transferred from Warsaw to Moscow. They fear, too, that upgrading research with practical applications will be used to justify cutbacks in other sectors, so as to cover a purge of political undesirables, terminating their research contracts on the grounds that no more funds are available. A painful example to scientists and scholars of every discipline is the fate of the Institute of Nuclear Research (IBJ) which in the winter of 1982–83 was dissolved and refounded as three institutes to weed out pro-Solidarity personnel without formally contravening the labour laws. If this could happen to IBJ, they argue, at a time when the government had just relaunched its nuclear energy programme, what are the prospects for an astrophysicist, a logician or a sociologist who falls foul of the system?

Not surprisingly, the trauma of martial law still haunts the scientific community. Formally, of course, all was forgiven and forgotten under the amnesties of 1983 and 1984. Interned and imprisoned scientists have been reinstated and the situation at IBJ officially explained as voluntary redundancies, premature retirements and the like. In fact, some of those reinstated under the amnesties have since been dismissed or eased out of their jobs (anecdotal evidence suggests that this process has been stepped up since the beginning of this year), while some formally convicted of offences against the martial law regulations have not been able to return to professional employment.

There seems to have been little consistency; of the two physicists on trial for anti-state activities when the 1984 amnesty put an end to the case, Dr Henryk Wujec has been allowed to return to his old place of employment, the Standards Office (through transferred to a different department), while Dr Zbigniew Romaszewski is unable to find a scientific post at all. A mathematics student convicted of distributing leaflets under martial law has found that, after graduation, he cannot obtain a job, whereas a class-mate similarly convicted has found no difficulty.

In some cases, exemplary punishment seems to have been inflicted almost at random: Dr Zbigniew Grabowski, a physical chemist, for example, had his election to the Academy of Sciences vetoed by the government, although his only "offence", like that of hundreds of his colleagues, was signing a petition against the imposition of martial law.

A particularly umpleasant penalty, which has revived the fears of the whole scientific community, was that inflicted on Dr Zofia Kuratowska, who, during martial law, had headed the medical service for the internment camps. Dr Kuratowska is employed by the Advanced Studies Centre of the Polish Academy of Medicine, and runs advanced training and updating courses for doctors and medical graduates from all over Poland.

In 1983, just as martial law was coming to an end, she says, she was informed by the security police that they intended to put an end to her professional career by closing down her clinic at the Barska Street a hospital in Warsaw. In spite of petitions from doctors, patients, nurses at the general public and last-minute appeal to the Council of State, the clinic was closed on 31 December 1984 (ostensibly because the wards were needed for other purposes), leaving 500 haematological and geriatric patients without proper medical cover, and interrupting the postgraduate courses.

Dr Kuratowska has found temporary accommodation for the courses (at least until the end of the year) at the partly-built Oncological Centre Ursynow, on the edge of Warsaw. She has no in-patient facilities there, however, and, she reports, five patients have already died as a result of the closure.

Such incidents, sporadic as they are, are sufficient to make the Polish scientific community apprehensive for its future. Already the autonomy of the universities, won in the Solidarity period, is under attack and the proposed new law on the Academy of Sciences, which was still being drafted when martial law intervened, has been quietly shelved.

A major innovation of that law would have been to make the academic secretary of the academy responsible to his fellow members and not, as at present, to the prime minister. How significant such a change would have been may be illustrated by the Gradbowski case: not only was his election to the academy vetoed, but the very fact of the election was stricken from the academy records.

To an increasing number of Polish scholars, the prospect of a purge is now only a matter of "when" and "how severe". At present, scientists and academics unable to find professional work can try to continue their theoretical research privately. An unofficial Social Committee for Learning administers a few bursaries for such scholars, at parity with the official pay scales for academy researchers (about two-thirds of the national average salary). A scheme that can help a couple of dozen distressed scholars however, is clearly not equipped to cope with the victims of a major purge.

Vera Rich

French science

Good times are here again

THE French socialist party, which forms the present government in France, took a knock at the polls last weekend when right-wing parties scored 58 per cent of the vote in local elections. Of course, the French economy took its dive later than others in the West, and the electorate blames it on the new government. They may be right. But President Mitterrand's administration does have at least one feather in its cap — science — and it was seen to be waving it vigorously last week before the elections.

According to a communiqué from the council of ministers last week, French research and development spending has leapt more than a fifth in real terms since 1980, from 1.85 per cent of gross national product in 1980 to 2.25 per cent this year. Basic science may not have done so well (against a rising dollar) but "France has thus begun to regain its position among its principal partners and foreign competitors", the communiqué claimed. The benefits would come later, the investment "furnishing a solid base or the second step in the politics of industrial renovation".

The trouble is that the first step has been restructuring and unemployment. The electorate, unfortunately for the government, observes decline now more clearly than growth later. Nevertheless, the government has again pinned its colours to scientific growth at an important moment, when the "law for science", the creation of the first socialist science minister, Jean-Pierre Chevènement, nears the end of its term.

To replace it, Hubert Curien, the present science minister, promises a new law to be presented to the National Assembly in the spring, while the council of ministers is announcing that "research and development are, in effect, the keys to the modernization of our country". Auspicious times for French science appear to be here again.

Yet there are problems. Curien has been making an assessment of the successes and failures of science policy over the past three years, and describes it as "incontestably positive". But industry has been slow to invest in research; the new labour rights of researchers (which are supposed to increase mobility) have only just come into force, and many basic research laboratories are suffering from under-equipment and too few hard dollars for materials and apparatus. French computing power is also way behind the competitors, despite a decision last year to allow laboratories — after ten years' moratorium — to buy foreign machines. Much cash was also wasted on ill-conceived national technology programmes.

The necessary structural reforms have now been accomplished, says Curien; the great revolution has been the acceptance by a largely left-wing university system of the need to cooperate with industry and by industry of universities as partners. The stage is set for real development, Curien would claim. "The decline of Europe in relation to the United States and Japan is not written in history", he wrote last week in the newspaper *Le Monde*. And France must develop with Europe: "Is science not one of the best cements for a still fragile but indispensable European cooperation?", he asks.

In France, a commission has been set up to study the proposed law for science. But already the council of ministers has promised scientists several benefits:

- An increase in cash available for laboratory equipment.
- A long-term policy for training and employment in research and development.
- The establishment of research more widely in industry.
- Continuance of the "great programmes of technological development" such as space, aeronautics, energy and the oceans.
- At the same time, reinforcement of the assessment of these programmes and other action so that corrections can be applied when things go wrong.
- Improvement of tax and other financial incentives to industry and to research.
- Continuance of the "strong priority" given to research and development.

Robert Walgate

Italian biotechnology

Planning to catch up rivals

Rome

A NEW centre for biotechnology research and development is being founded at Pomezia, 45 km south of Rome, by Menarini SaS, the Florence-based pharmaceutical company. Dr Alberto Aleotti, president of Menarini, says the company is investing 28,000 million lire in the new biotechnology centre.

The first goal of the centre will be the manufacture of TPA (tissue plasminogen activator) and its derivatives for human pharmaceutical purposes, using recombinant DNA technology developed by Creative Biomolecules, a California corporation founded in 1982 by the 36-year-old Italian, Roberto Crea, and Charles M. Cohen.

The agreement between Menarini and Creative Biomolecules is aimed at the production of an economic drug for the international market. The Pomezia team will include researchers from Italy, the United States and Britain. The first TPA for chemical and biological evaluation is expected in the summer. Crea, acknowledging that his project is not the first in the field — Genetech first cloned TRA in 1982 — says its objectives are superior.

Inaugurating the Menarini centre (and the toxicology research facility on the same site), Italian minister of research Luigi Granelli pointed to several encouraging signs of development in Italian biotechnology by way of international cooperation. The international genetic engineering centre of the United Nations Industrial Development Organization, to be based at Trieste, is one of these. But Granelli added that developments in this field in Europe as a whole are still not a sufficient counter to developments in Japan and the United States, perhaps because governments see their interests as stronger than supra national ventures.

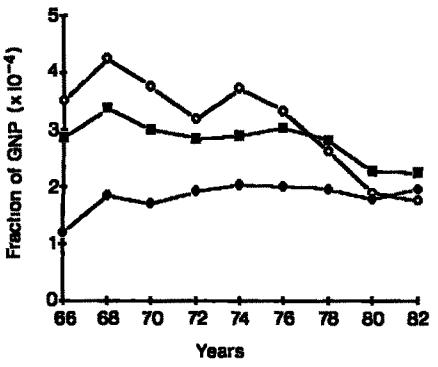
Italian biotechnology is in part held back by the lack of venture capital, with the result that most of the companies involved are either well established in some related field such as pharmaceuticals or are public enterprises. The companies with declared interests include Farmitalia-Carlo Erba (Montedison group, now under the umbrella of Erbamont), Lepetit and Serono. Sorin Biomedica (wholly owned by Fiat), Farmitalia and various companies of the ENI group have declared an interest in protein chemistry; Sclavo, an ENI company, plans to produce beta-interferon. Biotechnology in agriculture is quite advanced at ENEA, the public corporation for nuclear and alternative sources of energy, and Assoreni (ENI group) has interests in agricultural biotechnology.

University researchers have been drawn into biotechnology in various ways. Thus the multinational Roche facility at Milan has an agreement with the Pharmacology Institute of the University of Milan, headed by Professor Rodolfo Paoletti, for applications to molecular neurobiology. The Italian Society for Biotechnology (SIB) has signed a convention with IASM, the public sponsor of development in the south of Italy, and with FINAM, a financial holding for agriculture, to set up a centre for biotechnology transfer in the south.

The first objective of the centre will be to evaluate the degree of innovation in small and medium-size industries so that by the end of 1985 agricultural experiments on a pilot-plant scale may be started.

Projects sponsored by the Consiglio Nazionale delle Ricerche (CNR) have modest achievements to report. While the CNR genetic engineering programme, launched in 1982 with 20,000 million lire has so far recruited only a few participants among Italian industries, a 1980 project (due to finish this year) on fine chemicals under the direction of Professor Luciano Caglioti has worked with 500 different entities. So far, the project has published 1,800 scientific papers and produced 150 patents, some of which have already gone into production.

Paola de Paoli



CERN

Reduced budget in prospect

Geneva

BRITISH officials are beginning to sound out the 13 member states of CERN, the European Organisation for Nuclear Research near Geneva, to see if they would countenance a substantial reduction in the CERN budget (which amounts to some £250 million a year) while a fourteenth potential member, Portugal, has applied to join. Could Portugal pay for the reduction Britain requires? Certainly not, but the eagerness of Portugal and the dog-in-the-manger attitude of Britain make a sharp contrast seen from CERN.

Even Britain's backing of salary increases at CERN (*Nature* 7 February, p.423) could be a ploy in the long run of reducing salaries; negotiations begin this year for a major two-year review of the CERN salary structure. Britain, it is said, did not wish to begin on the wrong foot from the start of these negotiations (which Britain will chair) by backing a sudden and unprepared French move to cut pay.

The decline of Britain's spending on high-energy physics (open diamonds) as a fraction of gross national product, compared with that of West Germany, France, Italy and the United Kingdom jointly (full squares) and Belgium, the Netherlands, Sweden and Switzerland (full diamonds). Salaries are included.

By 1982, UK spending was already below that of the latter "medium size" members of CERN.

Thus Britain's head-counting looks ominous — particularly in the light of a committee chaired by molecular biologist Sir John Kendrew which will report soon on the value of Britain remaining a member of CERN. Sir John may praise the performance of CERN — it is, after all, at an all-time high in its history and even leading the world — but he may also criticize costs

Britain's real spending on high-energy physics has been declining rapidly (see Figure), but European investment remains a third above that of the United States when measured as a fraction of gross national product. CERN argues that this reflects the superior quality of CERN accelerators, and that without this quality Europe would not be in such a commanding position. Fermilab in the United States is three years behind CERN in creating the antiproton-proton collisions that at CERN created the W and Z particles and now hint at supersymmetry. But British accountants may find the benefits imponderable.

CERN, however, says that their next big accelerator (the large electron-positron collider, LEP) is being built on constant budgets, so that cuts are already being made throughout CERN to pay for LEP's construction. The director-general, Professor Herwig Schopper, is cutting staff, and accepts a Thatcherite hypothesis that every organization has some fat to lose. "But we're now cutting to the bone", says research director Ian Butterworth.

The bone is research. Over the past five years CERN has run double the number of research hours of its most direct competitor, Fermilab, says CERN technical director Giorgio Brianti. "We run a good deal — 7,000 hours a year, more than most nuclear power stations." But research after all is what investment in CERN is for.

Yet to cut running time, and hence electricity bills, might be the only real cut that CERN could now make. Already 70 per cent of the capital spending on LEP is committed. And salaries (half the CERN bill), while high by national standards, are low by international ones.

If running time were cut, physics would slow down, and competition from the United States would be more threatening.

Britain's possible complete departure from CERN is greeted with horror and disbelief in Geneva. CERN claims to have no contingency plans for the loss of Britain's 17 per cent contribution, or its physicists, though there would be a year or two to act (the constitution requires withdrawal on the January after the January following announcement of withdrawal).

Carlo Rubbia, the Italian discoverer of the W and Z particles, says Britain should go if it wants to, and not hang about like the character in Verdi's opera *Aida* who sings "I'm going, I'm going" for five acts but never leaves. Bob Brown, a British physicist in one of the four giant experiments to be mounted on LEP, says Britain's leaving "is too awful to contemplate". His experiment, OPAL, in which Britain has a major contribution (the provision of a lead-glass scintillator) "would collapse" if Britain left. Another LEP experiment, DELPHI, might be threatened.

Others say Britain just could not spend effectively the £50 million that the Science and Engineering Research Council would be left with if Britain left CERN; and that the research students presently staying in Britain to do high-energy physics (80 per cent of them with first class degrees) would simply go to the United States, weakening British science. In the longer run, non-members do participate in CERN experiments, but they make triple the normal contribution to apparatus, and Britain's problem would not thereby be solved.

"It would be a disaster" if Britain pulled out, said Schopper last week. "Would we throw out the British physicists? I cannot see that. But what would the other states say?". There would, in the end, be a limit to how long they would be willing to bail out a defaulter. **Robert Walgate**

No home yet for radiation source

THE European Synchrotron Source (ESRS), the 5-GeV light source that France and West Germany agreed should be built in France (in exchange for a supersonic wind tunnel to be built in Germany), is up for discussion yet again.

Now it is the turn of the Levaux Commission, the supposedly intergovernmental body set up by the European Science Foundation with the original aim of deciding the location of ESRS. France and West Germany effectively spurned the commission and decided among themselves (with British assistance) to put ESRS in France, hoping that the smaller states on the commission would agree.

But they did not; the situation was further complicated when the French government switched choices from Strasbourg (close to the German border) to Grenoble (in the French Alps), probably for electoral reasons. West German officials had always favoured Strasbourg, and were severely put out (though philosophical) when the French government changed its position.

Thus, when the Levaux Commission meets this week, French representatives will be all but isolated. France needs cash support to establish ESRS, and it is conceivable that strong pressure will be put on France to change its mind yet again. The regional elections feared by the French government, which could have displaced Louis Mermaz, the socialist president of the National Assembly, from his seat on the Grenoble regional assembly and perhaps precipitated a national election, are taking place last Sunday and next, so the internal political pressure will soon have changed. Not a stone has yet been turned for ESRS.

So could ESRS go to Strasbourg after all? Not if Denmark or Italy have their way, as Denmark still champions Risø and Italy Trieste. Scientific site visits to both places have taken place since France proclaimed the site would be Grenoble, and Italy continues to contest very loudly on behalf of Trieste. Last week, however, Italian physicists meeting in Trieste were talking of a compromise — the building of a 1.5 GeV synchrotron radiation source to "complement" the X-radiation from the 5-GeV ESRS in the lower wavelengths (soft X-rays and ultraviolet). Robert Walgate

Imunovir defended

SIR — In a letter published on 31 January[1], Dimitri Viza makes a number of assertions about Imunovir (inosine pranobex) and the "aggressive publicity campaign" which he suggests has been mounted to promote it. M. Visa's intention seems to be to criticize not just the product but also the journals and newspapers (specifically *Nature*, the *Sunday Times* and the *Financial Times*) which published articles on Imunovir (which is spelt with one m). In doing so he has made some errors, which I would like to correct.

First, M. Viza states that ". . . this drug is already better known from its promotion than its results". More than 300 papers have appeared on Imunovir, including many in journals such as *Lancet*, *International Journal of Immunopharmacology* and *Antimicrobial Agents and Chemotherapy*. As an example of this "promotion", M. Viza states ". . . US drugstore bookstalls hyped the drug with a paperback which claimed a cure for herpes . . . Although the author did not support this claims with any scientific publications, the book claimed him to be 'an authority on herpes'". The book in question, *Herpes: Cause and Control*[2], is an independent text on herpes by Dr William H. Wickett, former director of Student Health Services at California State University, Fullerton. The book discusses a wide range of preparations used to treat herpes, including acyclovir, idoxuridine and Imunovir. However, the latter is at all times referred to as "the test drug": not once is any generic or brand name used, and Dr Wickett states that this is at the request of the manufacturers. It is difficult to see how a book can "hype" a drug without once referring to it by name. Moreover, the book does not claim a cure for herpes. I quote Dr Wickett: "We found that those patients taking the test drug were cured of their Herpes bout in nearly 60% of the cases at the end of one week. Those taking the placebo were cured, by the same criteria, in about 14% of cases." Assuming that M. Viza is a doctor, he should know that herpes simplex is a recurrent disease and that curing a "bout" is not at all the same thing as curing the disease itself.

Neither the US discoverers of Imunovir, Newport Pharmaceuticals, nor Edwin Burgess Limited which distributes the product in the United Kingdom, has ever claimed that it can cure herpes. To quote the *Financial Times* article[3], also criticized by M. Viza, "[The company] is quick to point out, however, that the product is not a cure for viruses like herpes, only a moderator of the disease".

This brings me to another assertion, that if Imunovir is effective in herpes, the number of patients in France, Germany, Italy and Spain, where the drug has been available for some years, would have decreased. Imunovir certainly appears to reduce the severity[4-8] and frequency[9,10] of recurrent attacks of herpes simplex, but as it is not held up to be a cure, the number of patients with herpes can hardly be expected to decrease. In addition, the number of cases is probably related more to increasingly relaxed sexual attitudes than to available therapy.

To move on to the criticism of the article in the *Sunday Times*[11], it seems to be the headline that has caused offence: "Pill for AIDS — but it may come too late". Headlines are written not by authors of articles, but by sub-editors. In fact the *Sunday Times* article referred to work in "pre-AIDS" patients in New York, the results of which were presented to an audience of genitourinary specialists in London and are at present awaiting publication. The work was sufficiently encouraging for similar trials to be set up both in London and the United States to see whether the findings can be confirmed. These are now under way. The statement in the *Financial Times*[3] — "Imunovir may be able to prevent AIDS" — also refers to the New York study. M. Viza takes objection to another statement from that newspaper which suggests that Imunovir shows promising potential in a variety of diseases. I would like to draw his attention to the words of the jury which awarded Imunovir the "Prix Galien" in 1982, an award established in France to recognize major therapeutic innovation. (Other products honoured by the award include rifampicin in 1970 and cimetidine in 1979.) The distinguished professional jury stated that Imunovir "has transformed the basis of immune therapy and opens new hopes in the field of medicine as important and diverse as viral diseases, autoimmune disease, allergy, parasitology and cancer".

M. Viza is right when he says that responsible lay publications should not give rise to false hopes about potential "breakthroughs", and I believe that we would all be glad to see an end to sensational headlines which bear little relationship to the article, and to the "wonder drug" type of story in general. I dispute the idea that the articles to which M. Viza refers, including the one in *Nature*[12], are anything but well-balanced, responsible pieces of reporting based on the scientific evidence available.

Status of IVF embryos

SIR — An unfertilized egg is both human and alive, being a detached bit of its mother's body; but it cannot develop further without something positive being done to it from outside, namely fertilization. Otherwise it must inevitably die and, since nobody would claim that it therefore has a right to be fertilized, some would argue that if the "right to life" depends upon being human and alive, fertilization should make no real difference in this respect. But there is of course a fundamental difference, because when the egg fuses with the sperm a *new* living human organism comes into being, biologically as distinct from both of its parents as it will ever be, and none the less so for the possibility that it may still be able to give rise to twins. This newly created organism has within itself the potential to complete its development as a human person, which it will normally do unless it dies of its own accord, or is killed by a procured abortion. Whether or not at such an early stage it is to be regarded as a "human being", or only potentially one, it is hard to see what difference this should make to its rights to be allowed to realize its full potential without being deliberately destroyed.

There is however an important difference between the potential for futher development possessed by an egg fertilized normally inside its mother, and an embryo produced artificially by *in vitro* fertilization (IVF) outside her body. This is that whereas the embryo *in utero* has of itself the full potential to complete its development without any further intervention from outside, that is not so with IVF, when it requires another positive act in putting it back into a woman's uterus.

So far as completing its development is concerned, therefore, the IVF embryo can be compared with an unfertilized egg, since neither can do this without some positive intervention from outside. It is this, rather than the small size and lack of any visible signs of humanity, that may justify the use of IVF embryos for experimental work expected to result in death, which would anyway be unavoidable whether or not the experiments had been performed. The ethical problems that arise when embryos *in utero* are to be intentionally aborted are certainly quite different from those involved with experimentation *in vitro*, since even from the earliest stages they would otherwise have had a chance of completing their normal development.

Unborn Children (Protection) Bill

from H. John Evans and Anne McLaren

If the bill recently presented in the British Parliament were to become law, many promising avenues of research would be blocked.

MUCH to the dismay of most informed scientists, infertile couples and parents at risk of producing children with severe inherited genetic defects, Mr Enoch Powell's private member's bill effectively to ban studies on human embryos created by *in vitro* fertilization (IVF) won a majority when given its second reading in the British House of Commons, on 22 February.

The bill seeks to "render it unlawful for the human embryo created by *in vitro* fertilization to be used as the subject of an experiment or indeed, in any other purpose except to enable a woman to bear a child" (*Hansard*, 15 February, 1985). The bill does not seek to interfere with "procedures that are in use at present for enabling women who would not otherwise be able to do so, to bear children", but will, despite Mr Powell's comments to the contrary, effectively block any attempt to improve these, at present, rather inefficient procedures. The present success rate for human embryo transfer is of the order of 10 per cent. There is, however, no obvious reason why medical science should not be able to increase the efficiency of IVF and embryo transfer to achieve a success rate of at least 50 per cent. This will not be possible if this bill becomes law.

The passage of the bill would deny many thousands of couples in Britain (and 1 in 10 couples are infertile) the means to produce a family of their own, but this is not the only reason why a recent leading article in this journal (*Nature* 7 February, p. 417) described this bill as "home-made and half-baked" and a "blunderbuss" of a bill. Unfortunately, the bill will also prevent attempts to circumvent the production and transfer of severely genetically abnormal embryos, a possibility that is almost within the grasp of medical science, and which is ignored or rejected by proponents of the bill.

The Pro-Life group have lobbied all members of the British Parliament and organized petitions in support of the bill. Last month, Professor Jerome Lejeune was imported from Paris to address the Parliamentary Pro-Life group, and his views on curing inherited genetic disease[1] have been frequently quoted, misquoted and embellished, in support of the group's aims.

It is claimed that severely mentally retarded children with the fragile-X syndrome show improved mental development following treatment with folic acid; that azacytidine treatment of patients with β-thalassaemia may provide an effective therapy for this, and indeed other, inherited diseases; that vitamin therapy to the mother will drastically diminish the risk of spina bifida, and that these examples illustrate that experiments on human embryos are not required. They do no such thing. In fact, they are something of a red-herring, but before dismissing them we should at least look at the facts.

Therapy

The fragile-X syndrome afflicts some 1 in 1,000 males with mental retardation[2]. One diagnostic feature is the presence of a constricted and fragile region at the end of the X chromosome which is visible in a proportion of cells cultured in a medium deficient in folate. Adding folate prevents the cytological expression of this site[3]. This fragile site and the locus causing this form of mental retardation are closely linked, but it does not follow that they are one and the same locus. Indeed, the fragile site is not always readily demonstrable in males apparently afflicted with this form of mental retardation[4,5], while some mentally normal males possess a fragile X chromosome[6].

Folate deprivation also reveals reversible fragile sites on many other chromosomes[7], and they are not associated with mental retardation. The use of folic acid as a treatment for X-linked mental retardation has nevertheless been attempted in a number of small, and often uncontrolled, trials. Subjective "improvements" in the behaviour of some, but not other, folate-treated children have been reported, but with borderline[8] or no[9,10] changes in IQ. The results of these trials are unimpressive.

The proposed treatment for β-thalassaemia raises other questions. 5-Azacytidine (5-AZ) may be incorporated into DNA in place of thymine, but, unlike thymine, it cannot be methylated. Thus, in the presence of 5-AZ, genes whose functions are normally suppressed by methylation may become active[11]. In man, the genes coding for fetal γ-globin become methylated and turned off ("inactivated") after birth and their role in haemoglobin formation in the adult is taken over by the β-globin genes. So in patients with β-thalassaemia, where the genetic defect results in the absence of adult β-globin, one approach for therapy would be to maintain, or restore, the activity of the fetal γ-globin genes to compensate for the absence of functioning adult genes.

In 1982, Ley *et al.* reported[12] that a seven-day 5-AZ treatment of an adult patient with β-thalassaemia resulted in a temporary increase in the level of a fetal γ-globin. 5-AZ is, however, a very dangerous drug; it is likely to be carcinogenic and it also activates latent viruses. Its use would almost certainly be regarded as unethical in the United Kingdom. Although the rationale behind this possible therapy is clear, the longer-term consequences are not. Certainly more than the γ-globin DNA sequences would be expected to be "turned on" in proliferating cells and this kind of treatment could have bizarre, even lethal, consequences.

The third example quoted by the Pro-Life lobby is different in that it relates to a treatment of the mother who bears the fetus and is a preventative therapy. The possible role of vitamin supplementation in reducing the incidence of neural tube defects has been rehearsed in these columns before and will not be repeated. We might note, however, that the Medical Research Council has set up a "multicentre vitamin suplementation trial" to which the Pro-Life lobby has objected.

Understanding

Inherited defects contribute substantially to human ill health and considerable efforts are being expended in attempts to understand their nature and cause. This work very largely involves the use of cultured human somatic cells and its fruits could, in practice, be applied in various ways.

Defining and understanding the nature of the defect can lead to rational attempts to alleviate the disease, by supplementation (*à la* Lejeune) or by circumvention. Attempts at alleviation could, in theory, be undertaken at any stage in development. The widely publicized approach of somatic cell gene therapy in the late fetus or adult, using retroviral or plasmid-based expression vectors[13], and the recombinant DNA research that underpins it, have been the subject of much emotional debate[14].

Yet these developments are some way removed from practicality and, it should be emphasized, will be applicable to only a limited number of diseases. Moreover, they are concerned with attempted amelioration of the disease and not with its prevention. And they involve manipulation of the patient, not of the embryo.

Lejeune has made the point that research aimed at alleviating the symptoms of mental defects, as in Down's syndrome, cannot be performed on early human embryos, because at that stage the central nervous system has not even begun to develop. Similarly, he claims that research on the alleviation of muscular dystrophy cannot be carried out before the muscles are present. These are valid points, because Lejeune is concerned only with therapy. What Lejeune omits to say is that research on the detection and prevention of these genetic defects, and studies designed to increase our understanding of their aetiology, not only *can* be done on the pre-implantation conceptus (early embryo), since the defective genes or chromosomes are present throughout development, but in some instances can *only* be done at this early stage.

Unfortunately, some members of the Pro-Life lobby confuse the attempted treatments of patients with an inherited disease using genetic manipulations of the somatic cell, which may well be a desirable approach, with genetic manipulation of the embryo, which is not only clearly undesirable, but also unnecessary. With severe single-gene inherited disease, 50 per cent of the germ cells of carriers are normal. For an autosomal recessive disorder such as cystic fibrosis, 3 of 4 fertilized eggs produced by two carrier parents (around 1 in every 22 people in the United Kingdom are carriers of this abnormal gene) will result in normal children; for a carrier female of an X-linked recessive gene, as in Duchenne muscular dystrophy, all embryos destined to be female and one-half of those destined to be male (or 3 of 4) will be normal. A fertile carrier of a gene for an autosomal dominant disease such as Huntington's chorea will transmit that gene to one-half of his or her conceptuses. In all cases a proportion of the embryos will result in normal children. Provided we can detect which is normal and which abnormal, there is no need for genetic manipulation of the embryo.

Therefore, it is evident that if we could monitor for the presence of an abnormal gene of chromosomal constitution in an early embryo, then by the use of IVF and embryo transfer it would be possible to ensure that only normal embryos are transferred back to the mother in those families that are carriers of serious genetic disease. In the same way, infertile couples who partake of IVF and embryo transfer or those that are at risk of transmitting a chromosome anomaly, could be assured that the transferred embryos are chromosomally normal. (The first published announcement of the birth of a chromosomally abnormal child, a Down's syndrome baby, conceived by IVF and embryo transfer, has recently been reported[15].) Is it possible to carry out such monitoring? At present, the answer is no. But the means to undertake monitoring are just around the corner, and would require further studies which would become outlawed under Mr Powell's bill.

The chromosome constitution of an early human embryo can be established from a cytogenetic analysis of but a few cells, and such studies have already revealed a high incidence of chromosome abnormality in human embryos[16]. The possibility exists of determining the chromosome constitution of an 8-celled or 16-celled conceptus by removing one or two of its cells and culturing them for chromosome analysis. The conceptus would in the meantime be frozen and afterwards thawed out and transferred back into the woman only if the cells were shown to be normal. (The cells of the early conceptus are multipotential and it has already been shown that a frozen 8-celled human conceptus which has lost some of its cells can give rise to a normal fetus[17].)

The same approach could be used to detect the presence of specific abnormal genes. More and more DNA probes for genes responsible for severe genetic disease in man are becoming available, and further advances in technique will enable such genes to be detected in small cell samples. The means of preventing the transmission of certain severe inherited diseases (with, incidentally, a concomitant reduction in the requirement of abortions in the "at-risk" families) is therefore almost to hand, but their development and implementation will not be possible if the bill succeeds.

Infertility

It is already evident that the very high rate of chromosomal non-disjunction in our own species is responsible not only for many of the genetic defects at birth, but also for much infertility and early spontaneous abortion. We know nothing of its causes, but we do know that much of it arises during oocyte maturation, or during the fertilization process or the early cleavage divisions. *In vitro* studies of these stages of development could therefore throw light on the aetiology of chromosomal disorders.

It is in the field of infertility that research on human oocytes fertilized *in vitro* is most urgently needed and will have the most immediate impact. Already there are hundreds of couples in Britain who owe their babies to such research. The current inefficiency of IVF and embryo transfer can be rectified only if systematic studies of the variables involved can proceed. For instance, the nutritional conditions provided for the fertilized egg *in vitro* are almost certainly not optimal. The IVF conceptus has been shown to secrete chorionic gonadotropin[18], a hormone thought to be crucial for the success of implantation. Conditions of IVF that gave a conceptus secreting low levels of the hormone might well be suboptimal from the point of view of producing a pregnancy.

Male infertility is almost as common as female infertility, but is less tractable to treatment. IVF has proved useful in some cases, since fertilization *in vitro* can be achieved with relatively small numbers of sperm, but the techniques are primitive and more research into the fertilization process itself is needed.

Contraception

A further area in which IVF is already contributing is in the development of new contraceptives. Present contraceptive pills have some undesirable side effects, and attempts to develop a "male pill" have been fraught with problems. The ideal hormonal contraceptive would affect only the oocyte or the sperm and such compounds are now being developed. However, before they could be considered for use it is essential to know if they carry a risk of abnormal fertilization — this can only be ascertained through IVF using human gametes.

In an issue as important and as emotional as this, it is essential that our representatives in Parliament understand the consequences of the proposed legislation. Mr Enoch Powell's bill would make it a criminal offence for any human oocytes to be fertilized *in vitro* except for purposes of "embryo insertion". The endeavours of doctors and scientists to use IVF studies to reduce the numbers of spontaneous abortions and children born with genetic defects, to reduce the numbers of abortions induced on genetic grounds, to alleviate infertility and, by improving contraceptive measures, to reduce the rate of "social" abortions and the numbers of unwanted children — all these would cease. To call such a bill the "Unborn Children (Protection) Bill" seems a prime example of Orwell's Newspeak. □

Is gravitational energy real?

The long-recognized problem of Einstein's theory of gravitation, that gravitational energy is not unambiguously defined, may be unavoidable. But people keep trying.

BETWEEN Newton's time and the beginning of the twentieth century, most people were broadly speaking content with the notion of the potential energy of an object in a gravitational field. Following the Galileo legend, one had merely to drop a stone from a height to see its potential energy converted into kinetic energy. By the nineteenth century, the interplay between the two had become a way of solving practical problems, most elegantly by means of hamiltonian mechanics, but more crudely (as with a falling stone) by equating decreases of potential energy with concomitant increases of kinetic energy. But Einstein changed all that.

It is paradoxical that the best theory of gravitation yet has thrown gravitational potential energy into a confusing limbo. R. Penrose, in a recent paper (*Proc. R. Soc.* **A381**, 53; 1982) puts the point directly, if inelegantly, by noting that "it is perhaps ironic that energy conservation, a paradigmatic physical concept arising initially from Galileo's (1638) studies of the motion of bodies under gravity...should nevertheless have found no universally applicable formulation, within Einstein's theory, incorporating the energy of gravity itself". But people keep trying to define gravitational energy. The latest attempt of this kind, by D. Lynden-Bell and J. Katz (*Mon. Not. R. astr. Soc* **213**, 21; 1985), is intriguing chiefly as an illustration of the difficulties.

The underlying problem with gravitational potential energy in general relativity stems from the principle of equivalence, which logically enters the theory as an assumption, and which has as one of its consequences that an observer falling freely in a gravitational field will have the illusion that the field does not exist. In other words, it is always possible to get rid of a gravitational field by the choice of a suitably accelerated frame of reference. The principle of equivalence leads to the conclusion that free-falling objects always have the same acceleration (which is Galileo's observation). But if gravitational acceleration can always be transformed away, gravitational potential energy cannot have the significance attributed to it in classical mechanics.

Einstein naturally took up the question of how the classical conservation laws would be transferred into his new formalism. One of the frustrations that quickly became apparent is that this seemed not to be unambiguously possible, at least in the strict sense that the representation of a physical quantity should be independent of the coordinates in which this is done (or, technically, that its numerical value at any point should transform with changes of coordinates as does a tensor quantity).

The situation is really rather odd. What Einstein's general theory does is to relate the quantities describing the curvature of four-dimensional space (and which themselves are functions of the space and time coordinates) to a quantity called the energy-momentum tensor, a true physical quantity (in the sense of being a tensor and thus coordinate-free) which represents the energy and the momentum locked up both in matter and in fields other than the gravitational field, electromagnetism for example. Einstein's problem, in the years succeeding 1917, was to find some way of representing the total energy of a system — matter-energy, the energy of the electromagnetic field and of other fields as well as the energy of the gravitational field, together with the modern analogue of the old potential energy — so as then to show that this quantity is conserved.

Einstein recognized that his solution is not ideal. The best candidate for a conserved quantity representing energy is not strictly a tensor but, a construct from the quantities describing the curvature of space-time which is not a tensor in the strict sense but; a pseudo-tensor, *viz* a quantity depending on the coordinate system is Einstein's pseudo-tensor, not a quantity that exhibits on a microscopic scale the conservation of energy and of momentum.

So is there a buried scandal in general relativity? Einstein's failure (often repeated) to find a quantity representing energy and momentum whose microscopic conservation is self-evident does not imply that energy and momentum are not macroscopically conserved. The difficulty that immediately raises its head is that the verification of macroscopic energy conservation must necessarily be possible only within the framework of a particular macroscopic description of the Universe. And many model universes in which energy is not conserved, which are nevertheless inconsistent with energy conservation, have been constructed.

Are there some circumstances in which the definition of potential energy, or the energy of the gravitational field, is possible in terms of the variables that define that field? This is the path that Lynden-Bell and Katz have followed. Beginning with an observation due to J.A. Wheeler that the problem of the unambiguous definition of potential energy may be simpler in the conditions in which spherical symmetry applies, they seek to define the gravitational field energy unambiguously in such circumstances.

The argument goes like this. In a system in which there are only gravitating masses, there must be some quantity, a function of the space-time coordinates, whose integral over any space-like surface (say that corresponding to the present time) is equal to all the energy associated with the mass, its rest-energy and momentum, and its gravitational potential energy. The equations of general relativity allow calculation of the rest-energy from the descriptors of the curvature, so that the difference between the surface integral and the mass within the surface must be the gravitational potential energy. Thus, by considering the difference between the surface integral on two nearby space-like surfaces, it should be possible to define the density of gravitational potential energy, the field energy. Lynden-Bell and Katz pin down their calculation by making an artificial cut in space-time along some space-like surface in which, without loss of generality, they can suppose that space-time is flat.

Physically, the result makes sense. The energy locked up in the gravitational field (as distinct from the mass itself) does indeed decrease with distance from massive objects. Significantly, the field around a black hole turns out to contain the whole energy of the condensed object. This fits in well with the views of those who hold that the significant consequences of black holes are external. Lynden-Bell and Katz say that their result differs from that of the "Penrose school", a reference to Penrose's elegant generalization of general relativity to accommodate particles with spin. That, according to Lynden-Bell and Katz, puts all the energy of a black hole inside it.

The implications of this calculation will depend on whether it can be generalized to universes that are neither spherically symmetrical nor static. There seems to be good reason for hoping that something can be done. But if part of the essence of general relativity is that potential energy cannot be unambiguously defined except by reference to large-scale structure, there is bound always to be a degree of arbitrariness in the way in which the concept arises.

John Maddox

Astronomy

Gas in elliptical galaxies

from A.C. Fabian

IT HAS generally been held that early-type galaxies — lenticulars and ellipticals — are devoid of gas[1]. The gas lost by stars, both as the winds from red giants and as planetary nebulae, has been presumed to be blown out of the galaxies by the cumulative effect of supernova explosions. A galactic wind thus scours a galaxy clean of gas, explaining why only relatively minute quantities (and little star formation) have been detected at radio, optical or ultraviolet wavelengths. This picture, itself, is now being blown away by evidence from the *Einstein Observatory* satellite: a considerable number, and perhaps all, early-type galaxies contain large quanities of gas that are only detectable by their X-ray emission. A new compilation of the data[2] shows that the mass of gas in a large elliptical galaxy can be about the same as that in our own spiral Galaxy.

One of the first results[3] reported from the *Einstein Observatory* was that the Virgo cluster of galaxies appeared 'spotty' in X rays. Individual normal and early-type galaxies appeared as diffuse sources of X rays. Further work[4-6] showed that many other normal galaxies were also X-ray sources, and attention seems to have drifted away from the early-type galaxies to more exotic objects such as active galactic nuclei.

Spiral galaxies, such as our own and Andromeda (M31), are X-ray luminous because they contain populations of X-ray emitting binary star systems. Large elliptical galaxies, however, are about one hundred times more X-ray luminous than spirals, such that over 1,000 very bright X-ray binary sources would be required. That interstellar gas is a more likely candidate for the observed X-ray emission is demonstrated by the X-ray emitting 'plume' of NGC4406 (M86; ref. 3). This large elliptical galaxy is falling through the Virgo cluster at about 1500 km s^{-1} and much of its gas is being stripped out by interaction with the extended halo around M87, to form a tail or plume in its wake. The nearby active galaxy Centaurus A also shows diffuse X-ray emission[7] (apart from the nucleus, jet and so on) which is most likely due to a hot interstellar medium, and not binary X-ray sources. The gas in elliptical galaxies should be at X-ray temperatures, for gas lost from stars moving at speeds σ, relative to the galaxy, of a few hundred km s^{-1} should themalize to a temperature of between 10^6-10^7 K such that its sound speed is about σ.

W. Forman, C. Jones and W. Tucker have compiled[2] the *Einstein Observatory* X-ray data on 55 early-type galaxies, most of which show X-ray coronae, and have obtained results that are of considerable significance to studies of early-type galaxies. Crude spectral analysis shows that the emission is consistent with that from hot gas and not with that of known classes of X-ray binaries. Thus, most optically luminous lenticular and elliptical galaxies contain hot gas; they cannot blow winds. Supernova heating, which could have ejected the gas, must be much less than previously assumed.

An important application of these hot gaseous coronae is the measurement of the masses of early-type galaxies. If the gas is observed, then its bulk motion must be highly subsonic, otherwise impossibly large sources of mass are required to maintain a detectable density. Consequently the coronae must be close to hydrostatic equilibrium and

$$\frac{dP_{gas}}{dr} = -\varrho_{gas}\frac{GM(r)}{r^2}$$

Measurements of the X-ray surface brightness and temperature profiles yield the gas pressure, P_{gas}, and density, ϱ_{gas}, and thus the mass as a function of radius $M(r)$. The compiled data yield total masses of about $1-5\times10^{12}\,M_\odot$ out to 100 kpc for the best studied cases. Some of these galaxies are in the Virgo cluster but most are in the weak groups and some are relatively isolated. The X-ray data imply massive dark haloes around most elliptical galaxies. Their mass-to-light ratio is around 100 in solar units.

For detectable amounts of hot gas to accumulate in galaxies the gas must be cooling at a significant rate, already discussed in the context of a small subset of the present sample[8]. Gas must be cooling and objects condensing out of the resultant cooling flow at a rate of about one solar mass per year, so that the formation of stars in large elliptical galaxies take place at a rate not much less than it does in our own Galaxy. Their optical appearance, however, provides no indication for this. The conditions must be such that the high-mass stars that we normally associate with regions of star formation in our Galaxy are absent. The new stars in eliptical galaxies must be of very low mass, perhaps even below that for nuclear burning. We conclude that elliptical galaxies are not quite so full of old stars as previously thought, although one solar mass per year for a Hubble time does not yield a $10^{12}\,M_\odot$ galaxy. Nevertheless there are intriguing implications for the formation of galaxies and of the so-called dark matter associated with them.

We thus have an extremely powerful tool for measuring the mass profiles out to distances of 10 - 100 kpc and for studying the gas and energy flows in early-type galaxies. When are we going to see more data? Unfortunately, the *Einstein Observatory* re-entered the atmosphere three years ago and the telescope on the EXOSAT satellite is not sensitive enough to help out. ROSAT, to be launched in 2 - 3 years time, should detect many elliptical galaxies out to 100 Mpc or more and, in the 1990s, high-quality imaging X-ray spectroscopy should become routinely available for any elliptical galaxy. □

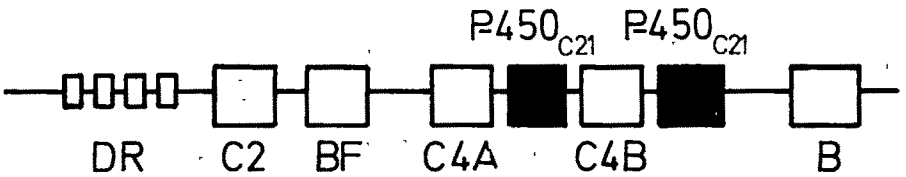
Congenital diseases

Complementary genes for an adrenal enzyme deficiency

from Ian R. Phillips and Elizabeth A. Shephard

ONE of the most common inborn errors of metabolism, congenital adrenal hyperplasia, results from a deficiency in the adrenal cortex of the enzyme 21-hydroxylase[1], which is involved in the biosynthesis of cortisol, the principle glucocorticoid hormone of the adrenal. The disease is inherited as a recessive trait and is closely, but enigmatically, linked to the major histocompatibility complex of humans, *HLA*. Two separate reports now help explain the linkage. First White *et al.*[2] show that the disease is due to a defect in a gene coding for cytochrome P- 450_{C21}, a protein that is specifically catalytic for the 21-hydroxylation of steroids. Second, Carroll *et al.*[3] have shown that the P- 450_{C21} genes lie within the HLA region of human chromosome 6.

Although the biochemical basis of the 21-hydroxylase deficiency has never been definitively established, steroid 21-hydroxylation can be catalysed *in vitro* by a combination of two microsomal membrane proteins of the adrenal cortex: P-450_{C21}, and a NADPH-dependent cytochrome P-450 reductase[4]. Since only the P-450_{C2} is specific for the reaction, White *et al*



hypothesized that the HLA-linked defect involves a structural gene for this protein. Their test of that hypothesis was facilitated by the knowledge that different forms of the disease are associated with characteristic HLA-B;DR antigens, and that 21-hydroxylase deficiency is in linkage disequilibrium with complement allotypes. For instance, all patients with the haplotype *HLA-(A3);Bw47;DR7* are deficient in both the complement protein C4 and 21-hydroxylase. This led White *et al.* to the additional hypothesis that the genes for C4 and 21-hydroxylase are closely linked and that patients with the Bw47 haplotype may have a large genetic deletion or rearrangement affecting both these genes.

This hypothesis was tested by the use of a cDNA clone coding for bovine P-450$_{C21}$ (ref. 5) to analyse the organization of the P-450$_{C21}$ gene in human DNA. Normal individuals are found to have two P-450$_{C21}$ genes. In the only patient homozygous for both 21-hydroxylase deficiency and HLA-Bw47 antigen, one of the P-450$_{C21}$ genes is deleted. Of patients homozygous for the deficiency but heterozygous for *Bw47*, one carries a homozygous deletion of a P-450$_{C21}$ gene whereas the others all have heterozygous deletions. The deletions segregate with the *Bw47* haplotype over three generations. Thus the *HLA-Bw47* associated 21-hydroxylase deficiency is due to a deletion of a P-450$_{C21}$ gene. However, in the majority of cases where the disease is associated with other HLA-B antigens, the defect is presumably due to much smaller mutations, the nature of which remains to be established.

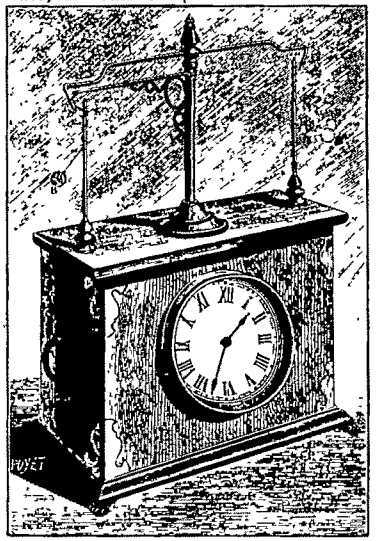
The elucidation of the molecular genetic basis of congenital adrenal hyperplasia will enable prenatal diagnosis at a much earlier stage than is possible with current methods. This is particularly significant because, in principle, it should be possible to alleviate the condition, at least in female foetuses, by treatment of the mother with dexamethasone.

The prediction of White *et al.* that *C4* and P-450$_{C21}$ genes are closely linked is borne out by Carroll *et al.*[3], beginning with the demonstration that a segment of human DNA containing the *C4* gene hybridizes to a 2.4 kilobase messenger RNA from tissue. Two copies of the gene corresponding to this mRNA are found to lie 1.5 kilobases downstream of the genes for the complement proteins C4A and C4B (see figure). The expression of the gene in the adrenal gland, the size of its mRNA and a partial sequence analysis indicate that it encodes a human P-450$_{C21}$. (Using a similar approach, White *et al.*[6] have demonstrated there are two P-450$_{C21}$ genes located immediately downstream of the *C4* gene and the related *s1p* gene of the mouse, suggesting that a P-450$_{C21}$ gene became linked to the major histocompatibility complex, and was duplicated along with an adjacent *C4* gene, sometime before the divergence of mammals).

In contrast to the genes coding for two other complement proteins, C2 and factor B, which lie one kilobase apart, 30 kilobases upstream from the *C4A* genes (see figure) and which probably arose by duplication of a common ancestral gene, P-450$_{C21}$ and *C4* are not similar in sequence. The significance of their close association is not clear and there is no obvious explanation for the presence in the major histocompatibility complex of genes coding for a steroidogenic enzyme.

Schematic map (not to scale) of the *HLA*-region of human chromosome 6 containing the pair of P-450$_{C21}$ genes. C2, C4A, C4B and BF (factor B) genes encode complement components; DR genes encode Class II HLA antigens and B gene encodes a Class I HLA antigen.

The function of the second P-450$_{C21}$ gene is as yet unknown and it would be of interest to establish whether the two P-450$_{C21}$ genes are highly conserved. It will also be interesting to discover the mechanism responsible for regulating the differential expression of the *C4* and P-450$_{C21}$ genes in liver and adrenals.



The 21-hydroxylase involved in congenital adrenal hyperplasia is a member of a 'superfamily' of proteins termed cytochromes P-450. Some members of this family, such as P-450$_{C21}$ itself, are involved in the metabolism of endogenous compounds, whereas others play a central role in the metabolism of foreign hydrophobic compounds, including drugs and carcinogens. Three cytochromes P-450 involved in the metabolism of foreign compounds have been mapped to chromosomes 7 and 9 in mouse[7,8] and genes coding for a drug-inducible cytochrome P-450 (ref. 9) have recently been mapped to chromosome 19 in man (E.A.S., I.R.P., M. Davis and S. Povey, unpublished observations). Just as a defect in a P-450$_{C21}$ gene has now been shown to be the cause of congenital adrenal hyperplasia, it is hoped that the availability of cloned DNAs coding for human cytochromes P-450 involved in the metabolism of drugs or chemical carcinogens will lead to a determination of the molecular-genetic basis of inherited variations in the ability of individuals to metabolize these substances. □

100 Years Ago — A New American Clock

THE accompanying figure from *La Nature* illustrates a new American clock of ingenious construction. It is distinguished from all other clocks by the singular and original form of its pendulum, based on the principal of torsion. A train of wheels gives rotation to a vertical axis, which is seen over the case, the rate of motion of which is to be regulated. This vertical axis supports a sort of bracket, P, to the extremity of which is attached a small bead or ball, B, by means of a thread a few centimetres long. The axis, by the action of the main spring, will turn with a rapid movement, drawing the ball B along with it. To regulate this movement, it is sought to interpose in its path suitable obstacles; this is the object of the horizontal wire terminating in the hooks T, and of the vertical pillars fixed on the case. The bracket P draws the thread in its movement and makes it strike against the arm T; it is thus arrested, and by virtue of its acquired speed, the ball B winds the thread around the pillar on the left; then follows an unwinding of the thread and a rewinding in an inverse direction, which enablesthe thread to pass the point T. But in unwinding it strikes a second time against the pillar, winds and unwinds anew, and only succeeds in passing this double obstacle after four successive windings, twice in one direction, and twice in the opposite direction around the same pillar. The thread thus set at liberty permits the bracket to turn 180° around the vertical axis. After this rotation it encounters two analogous objects placed on the right of the clock, and is delayed a certain time before passing these objects and returning to the pillar on the right. The clock is thus regulated, if not with all the precision of a chronometer, with an approximation said to be sufficient for ordinary use. From *Nature* **31** 439, 12 March, 1885.

Mathematics

How bent is a knot?

from Ian Stewart

Anyone who has fiddled about with one of those lengths of plastic-coated spring from which curtains are sometimes hung will have noticed that it is harder to bend the spring into a knotted loop than it is into a unknotted one. Since elastic energy is concentrated on curves, this suggests that a knot is in general more bent than a simple, unknotted loop. The natural context in which to ask whether any mathematical sense can be made of this observation is differential topology, a hybrid creation in which topological notions, such as knottedness and connectedness, are blended with analytical and differential-geometric ideas such as curvature and smoothness. It is one of the deeper areas of today's mathematics, with important successes and applications to its credit. Recent research by N.H. Kuiper and W. Meeks (*Inventiones Mathematicae* 77, 25; 1984) has uncovered some fundamental relations between the topology of a multi-dimensional space (or manifold) and its metric properties, notably curvature.

The notion of curvature goes back to C.F. Gauss in 1828. He defined curvature for surfaces, proved it was an intrinsic property, not dependent on the specific embedding of the surface in 3-space, and applied it to geodesy. It was generalized by B. Riemann to n-dimensional manifolds, and used by A. Einstein as a basic concept in general relativity. The earliest result relating curvature and topology is the Gauss-Bonnet Theorem: the total Gaussian curvature of a surface is $2\pi C$, where C is its Euler characteristic. This is a topological invariant, equal to $2-2g$, where g is the number of 'holes' in the surface. Roughly speaking, the Gauss-Bonnet theorem says that to make holes in a surface you have to put more bend into it. Its importance may be gauged from a remark in M. Spivak's *Differential Geometry* (a classic 5-volume text, described by its author as "The Great American Differential Geometry Book", published by Publish or Perish Inc.). Spivak says: "A whole slew of consequences follows immediately from this spectacular theorem, which expressed a differential geometric quantity in terms of a number which has nothing at all to do with curvature, or even with a Riemannian metric."

Opening remarks about the curvature of a knot can be made precise in a similar way. In 1949, J. Milnor and I. Fary proved that the total curvature of a knot is greater than 4π. For a planar convex loop, the total curvature is exactly 2π. The ordinary trefoil, or overhand knot, can be embedded in 3-space with a total curvature as close to 4π as required, so 4π is the 'best possible' bound.

Instead of knotting a loop in 3-space, topologists are extremely interested in knotting n-dimensional manifolds in N-space. Again, the intuitive expectation is that a knotted surface will have more bend in it than an unknotted one. The amount of bend is once more measured by the total curvature, which is 4π for a sphere and 0 for a torus (in their natural embeddings). Kuiper and Meeks prove a general result which implies, for example, that a knotted torus in 3-space must have total curvature greater than 16π.

To be specific, they relate the total curvature of an n-dimensional manifold M embedded in N-space, to two topological invariants. One of these depends only on the manifold M: it is a relative of the Euler characteristic, and is the sum, β, of the Betti numbers of M. The other depends on the way M is embedded, and measures the extent to which M is knotted: it is σ_1, the first homotopy excess. (Space limitations preclude a precise explanation of either invariant.) Kuiper and Meeks show that the total curvature must be at least $\frac{1}{2}V(n)(\beta+4\sigma_1)$, where $V(n)$ is the 'surface area' (or total curvature) of the n-dimensional unit sphere. For example $V(1) = 2\pi$, $V(2) = 4\pi$, $V(3) = 2\pi^2$, $V(4) = 8\pi^2/3$. There are, however, two exceptional pairs of dimensions. If $n = 1$ (M is a curve) then 4_1 must be replaced by 2_1. And if $n = 3$, $N = 4$, then ν_1 is replaced by the maximum of two similarly defined quantities, calculated for the interior and exterior of M. In these exceptional cases the results are due to R.H. Fox and P. Wintgen.

The proofs rely heavily on new techniques, including Morse Theory (the study of critical points such as maxima, minima, and saddles), the handle decomposition due to S. Smale, the notion of a tight embedding, and Meeks's work on surfaces known as multipants because of their resemblance to generalized trousers for multilegged creatures. The argument is delightfully geometric, as is most of the deeper work in differential topology.

Much of the power of mathematical reasoning derives from its ability to relate concepts that had not been seen to have any connection with each other. The curvature properties of knotted surfaces are an intriguing example of this process and part of a continuing drive to apply metric concepts, such as curvature, to the topology of manifolds. More detailed results along similar lines cannot be far away; meanwhile the view of Gauss and Riemann that curvature is a fundamental property of a space is being vindicated with a vengeance. □

Molecular genetics

Diverged genetic codes in protozoans and a bacterium

from Thomas D. Fox

THE genetic code, which is the same in *Homo sapiens* as in *Escherichia coli*, is widely thought to have been fixed prior to the divergence of all life forms and so to be universal. Since a mutation changing a codon assignment would effectively cause thousands of mistakes in the proteins translated, it has seemed quite reasonable to assume that such mutations would be lethal. Although studies on mitochondrial genes have shown that the code is not strictly universal, mitchondria could be thought of as exceptions that prove the rule: their genetic systems produce only a very limited number of proteins and so might tolerate changes. Now, some 'real' exceptions have come to light in both eukaryotic and prokaryotic free-living organisms, and the notion of universality will have to be discarded.

In the erstwhile universal code, the codons UAA and UAG mark the termination of translation of a sequence into protein. But in three different ciliated protozoans there is now a strong indication that UAA and UAG encode the amino acid glutamine. S. Horowitz and M.A. Gorovsky (*Proc. natn. Acad. Sci. U.S.A.* in the press) have determined partial sequences of two genes for histone H3 in the macronucleus of *Tetrahymena thermophila*. (Ciliated protozoans contain a 'somatic' macronucleus and a 'germ-line' micronucleus.) The gene sequences predict the known amino acids of the histone except that each sequence contains two UAA codons at positions that correspond to glutamine in the protein. Thus, UAA must be translated unless both cloned sequences are derived from pseudogenes, which are not translated. This seems unlikely since all 12 mismatches between the two partial H3 sequences produce silent changes. Southern blot experiments show that there are a maximum of four H3 genes in *T. thermophila*, at least two of which must be active since there are two variant forms of the protein in this organism. Thus, while it is possible that the two sequenced H3 genes are silent copies, it is much more likely that UAA actually encodes glutamine.

This conclusion is supported by com-

plementary evidence from another ciliated protozoan, *Stylonychia lemnae*, from which E. Helftenbein (*Nucleic Acids. Res.* **13**, 415; 1985) has cloned two different macronuclear genes that code for a protein which is very similar to the α-tubulins of chicken and rat. However, a UAA codon occurs in both genes at a position equivalent to that where the chicken and rat proteins contain glutamine. Since there are only two detectable α-tubulin genes in the *S. lemnae* genome, it seems that the cloned sequences must be active genes. It is hard to escape the conclusion that UAA is translated as glutamine in the α-tubulin gene of *S. lemnae*, which is terminated by a UGA codon, as are all other genes of ciliates examined to date.

Complementary evidence, reported in this issue from two laboratories, comes from the genes encoding variable surface antigens of *Paramecium*. On page 185, F. Caron and E. Meyer report a partial sequence of the single gene of *Paramecium primaurelia* that encodes the G-antigen. With standard codon assignments, the sequence contains no long open reading frame, but by expression in *E. coli* and sequencing of part of the G-antigen sequence fused to *LacZ*, Caron and Meyer were able to determine the reading frame for the G-antigen sequence in *P. primaurelia*. Interestingly, this frame is the only one of the three possible frames to have UAA and UAG codons but no UGA codons, except for a cluster to three near to the 3′ end of the transcribed region. Moreover, they show that the erstwhile stop codons are present in the G-antigen messenger RNA by using it as a template for sequencing reactions. Analysis of the A-antigen gene of *Paramecium tetraurelia* has led J.R. Preer *et al.* to similar conclusions. As reported on page 188, no long open reading frames are found in the sequences by standard codon assignments, but one frame predicts amino-acid compositions that are generally consistent with analysis of the protein, and this frame contains UAA and UAG, but not UGA codons. While there are no amino-acid sequence data for these surface antigens that allow definite codon assignments, the amino-acid composition data suggest that both UAA and UAG code for glutamine in *Paramecium*.

All of the ciliate genes examined contain the standard glutamine codons CAA and CAG in additon to UAA and UAG. Thus the latter pair could be thought of as resulting from the fixation of a high-efficiency suppressor gene, leaving UGA as the sole termination codon. How, or when, these events took place is anyone's guess. Either the line leading to ciliates diverged before the standard code was fixed or, perhaps more likely, the changes occ urred soon after the divergence of the line from ancestors that used the standard code. This could have happened at a very early stage since ciliates are highly divergent from other eukaryotes: as Horowitz and Gorovsky point out, "Literal use of.. molecular clocks can suggest that ciliates diverged from all other organisms before life originated on earth" (not strictly impossible, but unlikely).

In a prokaryotic organism too, *Mycoplasma capricolum*, divergence of the genetic code has now been demonstrated (Muto, A. *et al. Proc. Japan Acad.* in the press and Yamao, F. *Proc. natn. Acad. Sci. U.S.A.* in the press). This group finds that the sequences of the *M. capricolum* genes coding for the ribosomal proteins S3 and S16, which are highly homologous to S3 and S16 of *E. coli*, contain four UGA codons between them. Three of these occur at positions corresponding to tryptophan in the homologous *E. coli* proteins. Strong support for the idea that these UGAs are translated as trytophan comes from the sequences, determined by the same authors, of two *M. capricolum* genes for tryptophan-tRNA. One contains a standard 5′-CCA-3′ anticodon, but the other has the 5′-UCA-3′ anticodon that would be expected for a tryptophan-tRNA able to recognize UGA.

One cannot help but be struck by the fact that the coding of tryptophan by UGA now demonstrated for one species of *Mycoplasma* is true also of animal and fungal mitochondrial genes, and that some species of *Mycoplasma* can grow as intracellular parasites. So, are *Mycoplasma* closely related to the presumed prokaryotic progenitor of mitochondria? As exciting as this prospect seems, there are at least two reasons for believing it may not be true. First, in at least some mitochondria of higher plants, UGA does serve as a termination codon (A. Brennicke, personal communication), so the use of UGA to code for tryptophan may not have been a property of the common ancestor of mitochondria, if there was one. Second, unlike some other bacterial species which have cytochrome systems strikingly similar to those of mitochondria, *Mycoplasma* appear to lack cytochromes entirely (Pollack, J.D. *et al. J. Bact.* **146**, 907; 1981). It remains to be seen whether non-standard codon assignments will be of value in sorting out phylogenetic relationships or the origins of the genetic systems of intracellular organelles. □

Laser fusion

Hollow shells, shorter wavelengths

from Roger Evans

SINCE laser-driven inertial confinement fusion (ICF) was declassified in 1972, its somewhat chequered history has centred around the problem of symmetry. Using laser beams, the deuterium-tritium (DT) target pellet has to be compressed to as much as 200 g cm^{-3}, an enormous compression that distinguishes the ICF pellet from the hydrogen bomb. In both cases, the DT fuel must be heated to the thermonuclear ignition temperature of 10^8 K, but the much larger mass of fuel in a bomb need not be compressed to the same degree in order to achieve the combination of density, temperature and duration required to permit fusion — the equivalent of the Lawson criterion. Two recently published papers have shown major advances in solving the symmetry problem and give a renewed vigour to inertial confinement research[1,2].

In the original paper on laser-driven ICF, Nuckolls[3] suggested imploding a small solid pellet of DT fuel, but later Kidder[4] showed that the laser power required could be significantly reduced if the fuel were a hollow spherical shell instead of a solid. For a given fuel mass, this would be larger, its implosion time would be longer, the laser energy could be delivered over a longer time and the power level would be reduced. The extent of this gain depends on the ratio of the shell thickness to its radius, known as the 'aspect ratio'; large thin shells require less laser power to achieve the same degree of compression.

This advantage is not without its drawbacks as the imploding hollow shell suffers from the Rayleigh-Taylor fluid instability. This occurs whenever a dense fluid is supported by a light fluid under gravity. Any distortion of the fluid interface is amplified, resulting in 'spikes' of dense fluid falling while 'bubbles' of the light fluid rise upwards. In laser-imploded targets the gravity is provided by the acceleration, the tenuous plasma heated by the incoming laser light is the light fluid, and the solid shell of imploding material is the heavy fluid. The overall growth of the Rayleigh-Taylor instability scales as the square root of the shell aspect ratio, so that impossible levels of smoothness and illumination uniformity are required for shells of high aspect ratio.

The advantages gained from reducing the laser power with large aspect-ratio shells are not simply the economies of reducing laser costs but are quite fundamental, because light of lower intensity has a more favourable interaction with the target plasma. As the laser intensity increases, a greater proportion of energy goes into removing material from the pellet at the expense of compression efficiency. A major recent advance was the realization that shorter laser wavelengths allow the use of higher light intensities while maintaining good coupling efficiency, because the shorter wavelength light penetrates to

higher densities and thus ablates more material at slower velocity, resulting in more efficient compression. However, coupling the laser energy into high density material reacts back on to the problem of symmetry. No real laser system is ever likely to produce the one per cent symmetry (defined as the fluctuation in laser luminosity over the target's surface) needed to drive a high-density implosion, and some reliance is placed on 'smoothing' the non-uniform illumination within the target atmosphere. Since the short wavelength laser light penetrates further, there is clearly less atmosphere to effect the smoothing and the requirement for illumination symmetry is correspondingly tighter.

The growth of the laser-driven Rayleigh-Taylor instability in flat foil targets has now been measured by workers at the US Naval Research Laboratory[1]. Although this is not the first such measurement[5], it is the first time that two-dimensional images have been obtained. It was made with a flat-foil target, the rear surface of which was grooved like a diffraction grating to act as a 'seed' for the Rayleigh-Taylor instability, accelerated with about 500 J of laser energy at 1.06 μm wavelength. When the instability grows, the line of sight passing through the 'spike' contains much more material than an adjacent sight line passing through the 'bubble' and gives rise to differences in transmission in a flash X-ray radiograph. Comparing the results with sophisticated computer models shows that the growth rate is about half of the classical value. It has been suggested that the reduction is due to the ablation of fluid across the Rayleigh-Taylor unstable region, which gives rise to the classical phenomenon of vortex shedding. If correct, this is good news for short-wavelength laser users because the increased ablation flow should give rise to a further reduction in the Rayleigh-Taylor growth rate.

A second paper[2], from the Osaka group in Japan, reflects the very heavy involvement of the Japanese in fusion research, and particularly in laser fusion, where their Gekko XII glass laser is currently the most powerful in operation anywhere[6]. This group has tackled the problem of uniform illumination in a very imaginative way: instead of trying to achieve the most uniform illumination, use has been made of the paradoxical finding that really bad laser beams can be more effective than good ones, because the target is most sensitive to a particular range of spatial periodicities. Very short wavelength non-uniformities can be removed by the smoothing of the target atmosphere, while wavelengths that are very long compared with the target radius grow quite slowly and are not very damaging.

The Japanese solution is to divide the laser wavefront into a multitude of small rectangular beamlets and to introduce phase delays between adjacent beamlets with a 'random phase mask'. Each beamlet is sufficiently small that, when focused on to the target, its diffraction-limited spot is about equal to the target size; the target sees a large number of diffraction-limited, and therefore smooth, beams. Since the beams are all coherent with each other, they interfere in the target plane and give rise to a scrambled intensity pattern with a very short characteristic wavelength. The Japanese group has performed several target experiments using the random phase mask and has reported favourably on its effectiveness.

The combination of these two new results and other successful implosion experiments reported at the recent International Atomic Energy Agency meeting in London[6] renews enthusiasm for short-wavelength lasers as fusion drivers. Further progress is eagerly anticipated. □

Prehistoric astronomy

Evidence from a new site

from Clive Ruggles

THE ashes of an old and fiery debate on the reality of 'megalithic astronomy' will be stirred by the paper on page 158 of this issue, in which MacKie *et al.* describe, and provocatively interpret, a newly-excavated site in Scotland.

Five years ago it was possible to believe that 'megalithic astonomy' was becoming a sterile field of research. Interest had waned in Stonehenge — for many years the epitome of a supposedly astronomical site — because many highly speculative interpretations, some of which had received wide publicity, had largely been refuted. The long debates generated by one or two high-precision astronomical alignments at a few 'classic' sites, such as Ballochroy in Kintyre and Kilmartin (Temple Wood) in Argyll, were also slackening off, essentially for lack of evidence to assess whether the alignments were deliberate or simply arose by chance.

The meticulous statistical analyses of Alexander Thom, combining evidence from many sites, were then claiming a level of precision for prehistoric lunar observations as little as two minutes of arc, which is quite beyond what seems to be possible, even after observation periods of 200 years. The objectivity of Thom's selection of data was being called into question; and, as a result, so were a number of his claims from earlier analyses, such as the existence of a calendar formed by dividing the solar year into sixteen equal parts, and of indicated horizon foresights marking 'calendrical' declinations.

These claims were starting to be the subject of thorough reassessment by critics from the numerate disciplines, although for many archaeologists this reassessment was redundant. For years they had regarded with grave suspicion the conclusions of astronomers, engineers and the like who, fascinated by the idea of prehistoric astronomy, specifically sought out evidence for it. The dangers in so doing are twofold. First, we may miss or misinterpret a wide range of other evidence bearing upon the purpose of a site and its builders. Second, we may unwittingly project our own ideas of 'achievement' on to the culture whose material remains we are studying. Such ethnocentrism seemed blatant in the approach of those who talked of 'megalithic observatories' — sites considered to have been primarily constructed for careful observation of the Sun, Moon and stars — and led many to dismiss out of hand the conclusions of Thom and others.

Recent developments have changed general attitudes towards prehistoric astronomy. First, there has been a movement away from the consideration of individual sites, towards a more archaeologically-informed assessment of evidence from coherent combinations of sites. Statistical analyses now pay greater attention to the objective selection of data, and the whole approach recognizes that astronomical considerations will be only one amongst a number of factors influencing the placement and design of a site. This sort of approach has uncovered evidence of low-precision lunar alignments amongst linear settings in western Scotland and the Recumbent Stone Circles of Aberdeenshire. At the same time, severe doubt has been cast upon the hypothesis of observations more precise than one or two degrees (including Thom's solar calendar).

Second, archaeologists have begun to consider astronomical practice as but one aspect of ritual activity undertaken at ceremonial sites. Thus by relating evidence of lunar orientation to excavated evidence at the Recumbent Stone Circles, Aubrey Burl has concluded that the sites had a ceremonial significance in which lunar symbolism was important. The increased communication between those trained in the sciences and those trained in the humanities has lain the seeds of more general attempts to study and understand prehistoric astronomy, not in isolation but more properly in relation to its social context.

While statistical analyses must continue to play a crucial role, investigations of particular sites still have something to

offer, particularly if their excavation is designed to test a particular astronomical hypothesis rather than simply to collect data. A long-standing proponent of this approach has been Euan MacKie, who in 1970 and 1971 excavated a structure at Kintraw, Argyll, claimed by Thom to be an observing platform. Although widely quoted, the evidence from the excavation was unfortunately inconclusive, as MacKie himself now admits. In this issue of *Nature* he and his co-authors discuss evidence from Minard — another site in Argyll — where archaeological excavation was seen as testing an astronomical hypothesis. Perhaps the most striking result is that, unlike Kintraw, Minard indisputably has platforms that have been levelled by man; moreover, the main features at the site have been fairly securely radiocarbon dated to the mid-second millennium BC. Together, the various archaeological discoveries indicate that Minard was not a domestic, defensive, industrial or funerary site, but one intended, perhaps almost exclusively, for ritual use. Furthermore, both the striking distant horizon to the north-east, roughly in the direction of midsummer sunrise, and the general orientation of the site in this direction, seems to indicate that solar orientation was a deliberate and crucial function of the site.

Those interested in prehistoric astronomy will still have many questions to raise about the precise interpretation of Minard. In particular, many will dispute whether, on statistical grounds, the claim that it was used for high-precision observations (supporting Thom's 'calendrical' hypothesis) is really borne out. The north-eastern horizon foresight does not fall

Minard, Argyll. Was the site used for astronomy in megalithic times?

exactly at the solstice, and any feature occurring within a few degrees of the solstitial position is susceptible to the 'halving the difference' argument used by MacKie *et al.* (*viz*). There are similar problems when defining the 'calendrical' equinox. Thus the evidence for high-precision astronomy is perhaps not as clear as MacKie's paper might lead us to believe; nonetheless Minard is surely destined to become an important site, evidence from which will generate considerable debate and, I hope, a few fresh hypotheses. □

Genetic analysis

Of man and mouse

from P.N. Goodfellow

ON page 181 of this issue B. Robert *et al.*[1] describe their determination of the chromosomal localization of the genes that code for several muscle proteins of the mouse. These results will engage those studying co-ordinate regulation of muscle proteins and those interested in the evolution of gene families. More importantly, by exploiting the species differences between *Mus domesticus* and *Mus spretus*, Robert *et al.* introduce a new technique of mapping genes to chromosomes that may well become a standard tool for genetic analysis of the mouse.

The laboratory mouse has many advantages over man for genetic analysis, including a short generation time, plentiful genetic markers, and no restrictions on brother-sister or parent-child matings. So great were the advantages of working with mice that many geneticists believed that the proper study of man was mouse, a view which was encouraged by the development of inbred[2], congenic[3] and recombinant-inbred strains[4]. Without these tools, it is doubtful whether many familiar systems, such as the genetics of transplantation and immune response, would yet have been unravelled.

Two advances have made the direct study of human genetics as profitable as the study of the mouse. First, the introduction of somatic cell techniques freed human genetics from the disadvantage of the long human life span and exploited the species differences between humans and rodents to provide genetic markers; using this method over 400 loci have been assigned, directly or indirectly, to human autosomes[5], whereas only two or three had been assigned before the application of somatic cell genetics[6]. Second, in recent years, molecular biology has provided an almost limitless supply of genetic markers in the form of restriction fragment length polymorphisms (RFLP) defined by cloned DNA probes (see ref.7 for a recent review and ref.8 for the latest advance). These markers have rejuvenated classical genetic approaches and have already contributed to the chromosomal localization of loci associated with muscular dystrophy[9] and Huntington's disease[10].

Mouse genetics has also benefitted from somatic cell techniques and molecular biology but because of the related origin of the common inbred mouse strains[11,12] and the small number of strains available[2], it more difficult in mouse than in man to find RFLPs that can be used as genetic markers. To overcome this deficiency, Robert *et al.* mated an inbred strain of the laboratory mouse, *Mus domesticus*, to an inbred strain of the related mouse, *Mus spretus*[13]. The two progenitors of the laboratory mouse, *Mus musculus* and *Mus domesticus*, have been separated from *Mus spretus* for about three million years[14], which is sufficient time for there to have been enough divergence in DNA sequences to generate potential RFLPs in any cloned mouse gene.

In the wild, *Mus domesticus* and *Mus spretus* probably never mate with each other[15], but, under carefully provided laboratory conditions, fertile female offspring can be produced[13] and back-crossed to the parental strains[16]. (The male offspring of the between-species cross are infertile, as predicted by Haldane's law[17]). As demonstrated by Robert *et al.* for myosin alkali-light chain genes[1], linkage between the RFLPs and other genetic markers can easily be followed in the back cross and used for gene mapping.

For some genetic studies, including deliberate mutagenesis, the mouse will always be the mammal of choice. Ethylnitrosourea can induce mutations at the incredibly high frequency of one mutant at each locus for every thousand offspring[18]. This means that saturation mutation mapping[19] and the deliberate creation of mouse models for human disease are both feasible. Perhaps the proper study of man is both man and mouse. □

Histidine-rich protein of *Plasmodium lophurae*

SIR — Ravetch *et al.* have reported some very interesting findings on the primary structure and genomic organization of the histidine-rich protein of *Plasmodium lophurae*[1]. Their observation of the presence of multiple copies of the signal-peptide sequence in the genome of *P. lophurae*, along with the increasing evidence for the presence of histidine-rich sequences in additional malarial polypeptides, pose numerous challenging questions. The fragmentary available information seems to suggest that some related sequences have been conserved through the evolution of apparently functionally different malarial polypeptides.

The recent literature on histidine-rich proteins of malaria parasites has certainly had inconsistencies and can seem confusing to newcomers to the field. This creates all the more reason for factual reporting. Until 1983, the unique and fully characterized histidine-rich protein of *P. lophurae* was referred to as the 'HRP' of *P. lophurae* in all the malarial literature. Although in my publications a clear distinction has been set between HRP and other related polypeptides, there have been several references to undefined histidine-containing malarial polypeptides as 'HRP'.

Perhaps by confusing fact with hypothesis or different histidine-rich polypeptides, Ravetch *et al.* have taken their interesting findings totally out of the context of *P. lophurae*. They cite my paper[2] as their source for the statement that the histidine-rich protein "is located in a membrane-bounded compartment that forms part of the specialized parasite organelles implicated in erythrocyte invasion". Technically, these specialized organelles are the rhoptries of merozoites, the infective forms. However, the facts presented in the paper cited show that the protein was purified from cytoplasmic granules of trophozoite stages of *P. lophurae*[2]. As the parasites develop, the granules increase in number and eventually become segregated inside the residual food vacuole. When the host cells lyse and merozoites are liberated, the granules remain enclosed in the food vacuole which is also released.

These facts offer no grounds for speculating that "if histidine-rich protein becomes a surface molecule of *P. lophurae*, it must be secreted" or "if secretion does occur, it would be followed by disassembly of protein aggregates before association with the parasite surface". As shown in the electron micrograph of my paper, the protein aggregates in the form of electron dense granules while it is within the rough endoplasmic reticulum. Therefore, the logical interpretation of the observed structural features which are characteristic of secretory proteins has to be sought in the context of the synthesis and translocation of the polypeptide within cytoplasmic compartments of the parasite, rather than secretion to the surface. I have described a secretory polypeptide that is related to the histidine-rich protein of *P. lophurae* but it is in another species of malaria. Also, the idea of the possible relationship of a histidine-rich protein to the infection process does originate from my paper entitled 'Does a histidine-rich protein from *Plasmodium lophurae* have a function in merozoite penetration?'[3]. This was published as a hypothesis and has been neither proven nor disproven. I would be delighted to see it proven.

Ravetch *et al.* seem confident of the accuracy of the tandemly repeated sequence. In comparison with the known amino acid composition of the mature polypeptide, the deduced sequence shows significant differences in proline and aspartic acid content. In our hands, the histidine-rich sequences of both genomic and cDNA clones were totally unstable in *Escherichia coli*.

Finally, the statement that "other investigators have been unable to reproduce" my results on the protective effect of the histidine-rich protein cannot be supported by the literature cited. The use of altered experimental protocols does not imply "reproduction".

Climatic effects of volcanic eruptions

SIR — Major volcanic eruptions in the future will cause, as they have in the past, significant short-term climatic changes, and these changes may have severe social consequences[1-5]. Recent discussions of the climatic effects of volcanic eruptions have emphasized their importance as analogues of the consequences of nuclear war[1,2]. While studies of volcanic eruptions can make an important contribution to assessing the effects of a possible nuclear war, we fear that to use volcanic studies in this way draws attention away from the very serious problems that the eruptions themselves present. A nuclear war remains, fortunately, only a hypothetical possibility. But it is certain that climate-altering volcanic eruptions will take place in the future, although the frequency of these is not well established[6].

The most recent such eruption, that of Tambora 1815, caused widespread disruption to agriculture in North America and Europe, leading to economic crises, famine and outbreaks of disease, whose effects have been summarized by Stommel and Stommel[7]. The stratospheric aerosol loading produced by Tambora was equivalent to a peak optical depth of about 1 (ref. 3). Much the largest effects of historic times appear to have been associated with a volcanic aerosol of unknown provenance of AD 536, calculated to have had an optical depth of about 2.5, which had severe effects on agriculture in the Middle East[4]. Several other historic eruptions have had less severe but still significant effects, notably the Laki eruption of 1783[8].

Since 1815, the world's population has increased many-fold. The continuing famines in the arid and semi-arid regions of northern Africa demonstrate the disastrous human problems that result when relatively minor climatic changes affect marginal areas which are already at or near their maximum sustainable populations. An eruption of the magnitude of Tambora taking place at the present day could have catastrophic effects on agriculture, causing crop failures and shortages world wide, with substantial social and political implications. The fact that the frequency of such large volcanic eruptions may be rather low[3] offers little comfort: a Tambora or even a Toba magnitude eruption could take place tomorrow. Furthermore, the climatic effects of volcanic eruptions are a function of their ability to produce stratospheric aerosols as well as their absolute magnitudes[9,10]. Eruptions smaller than that at Tambora could therefore cause acute problems, especially given the present human pressure on food supplies.

Whilst not wishing to minimize the importance of research on the climatic effects of nuclear war, we suggest that some effort should be diverted from the hypothetical to the inevitable, and that attempts be made to determine the possible climatic and agricultural effects of future large and intermediate magnitude volcanic eruptions. Governments and international agencies might then be in a position to prepare contingency plans capable of dealing with the likely eventualities.

Origin of strong interplanetary shocks

A. Hewish, S. J. Tappin & G. R. Gapper

Mullard Radio Astronomy Observatory, Cavendish Laboratory, Madingley Road, Cambridge CB3 OHE, UK

Observations of 900 radio sources have been used to study the shape and motion of large-scale interplanetary transients associated with shock disturbances at 1 AU. The variations of plasma density and speed and the zones in the solar atmosphere from which the transients originate suggest an origin related to intermittent flows of enhanced speed from coronal holes at mid-latitudes on the Sun.

A BETTER understanding of the mechanisms involved in the genesis of strong interplanetary shocks is important not only to solar physics, but also for practical reasons concerned with disturbances to communication systems, electrical power transmission, geomagnetic surveys and with possible radiation hazards to astronauts[1,2]. New information about the shape and dynamics of large-scale interplanetary transients is now becoming available from radio astronomical measurements on a large grid of 900–2,500 radio sources whose scintillation can be used to monitor perturbations of plasma density along many lines of sight through the interplanetary medium[3]. The ability to map the disturbances and to estimate their speed and direction of travel is helpful in locating their sources at the Sun. Here, we present observations of interplanetary transients associated with three of the strongest shocks that reached the Earth during 1978–79: about 70 other examples were found during this period of high solar activity and will be presented in detail elsewhere.

Plasma density

Our observational methods and techniques of data reduction have been described before[3,4]. For each source we measure ΔS, the r.m.s. variation of flux density at 81.5 MHz integrated over the band 0.1–3.0 Hz during an interval of about 30–50 s at meridian transit. ΔS varies systematically with solar elongation in a manner which can be determined accurately from daily observations continued for about 1 yr. To specify day-to-day perturbations about the mean, we define an enhancement factor $g = \Delta S/\overline{\Delta S}$, where $\overline{\Delta S}$ is the average value for a given source at a particular elongation.

It has long been known that variations of g are correlated strongly with variations of total plasma density along the line of sight to a source[3]. It has also been suggested that enhanced turbulence, rather than enhanced density, may sometimes be correlated with increased scintillation[5]. This possibility is important for the present study, where lines of sight pass frequently through post-shock flows, so we have performed an analysis to check the correlation under a variety of interplanetary conditions. The large grid of 900–2,500 sources under daily observation enables this to be performed more accurately than had previously been possible.

The region of the solar plasma responsible for scintillation at 81.5 MHz is sketched in Fig. 1*a*. On 30 occasions during 1978–81, when we were fairly certain that stable conditions persisted along most of the relevant portions of appropriately located lines of sight, we obtained the results shown in Fig. 1*b*. The observations refer to lines of sight within 30° of the ecliptic at elongations near 90°, so that the best comparison could be made with near-Earth spacecraft data; a full account of this work will be given elsewhere. Occasions were selected when the *in situ* density remained approximately constant for at least 24 h and the average value of g was obtained typically from observations of 50–100 sources. The conditions giving rise to perturbed plasma density included both relatively stable co-rotating streams and more sudden transients often associated with shocks.

Our results are shown in Fig. 1*b*, which demonstrates the strong correlation between plasma density (N) and g. Over the range $3 < N < 40$ cm^{-3} the observations satisfy a relation $g = (N\,\text{cm}^{-3}/9)^{0.52\pm0.05}$. During the 2-yr period near sunspot maximum, we found no evidence for enhanced or decreased scintillation not associated with corresponding variations of density. We therefore conclude that scintillation can be used with confidence to monitor plasma density along the line of sight to a source under widely differing heliospheric conditions.

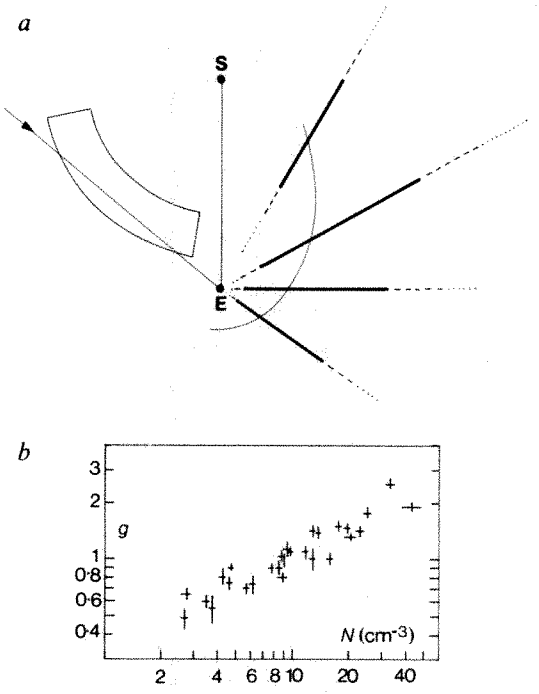

Fig. 1 *a*, Schematic diagram of scintillation weighting functions along various lines of sight normalized to unity at the locus of maximum scatterng (curved line). The ranges are: 0.5–1.0 (heavy line), 0.25–0.5 (dashed line), 0.1–0.25 (dotted). S, Sun; E, Earth. *b*, Correlation of scintillation enhancement factor (g) with *in situ* plasma density N. Each point is the average of observations of 50–100 sources at elongations near 90°.

The technique is best suited to the detection of large disturbances which cover the heavily weighted portions of the lines of sight. Shell-type transients thinner than ~0.05 AU might be undetectable. As our observations are made at meridian transit, there is also a finite chance that some disturbances could pass through the zone of detectability unobserved if they travelled faster than ~1,000 km s^{-1}.

Observations

The transients to be discussed caused sudden-commencement magnetic storms when they reached the Earth, followed by the strongest geomagnetic disturbances (Ap > 100) during August 1978–September 1979 and were also accompanied by energetic particles.

Contour maps showing the variations of g across the sky as the transients propagated outwards from the Sun are shown in

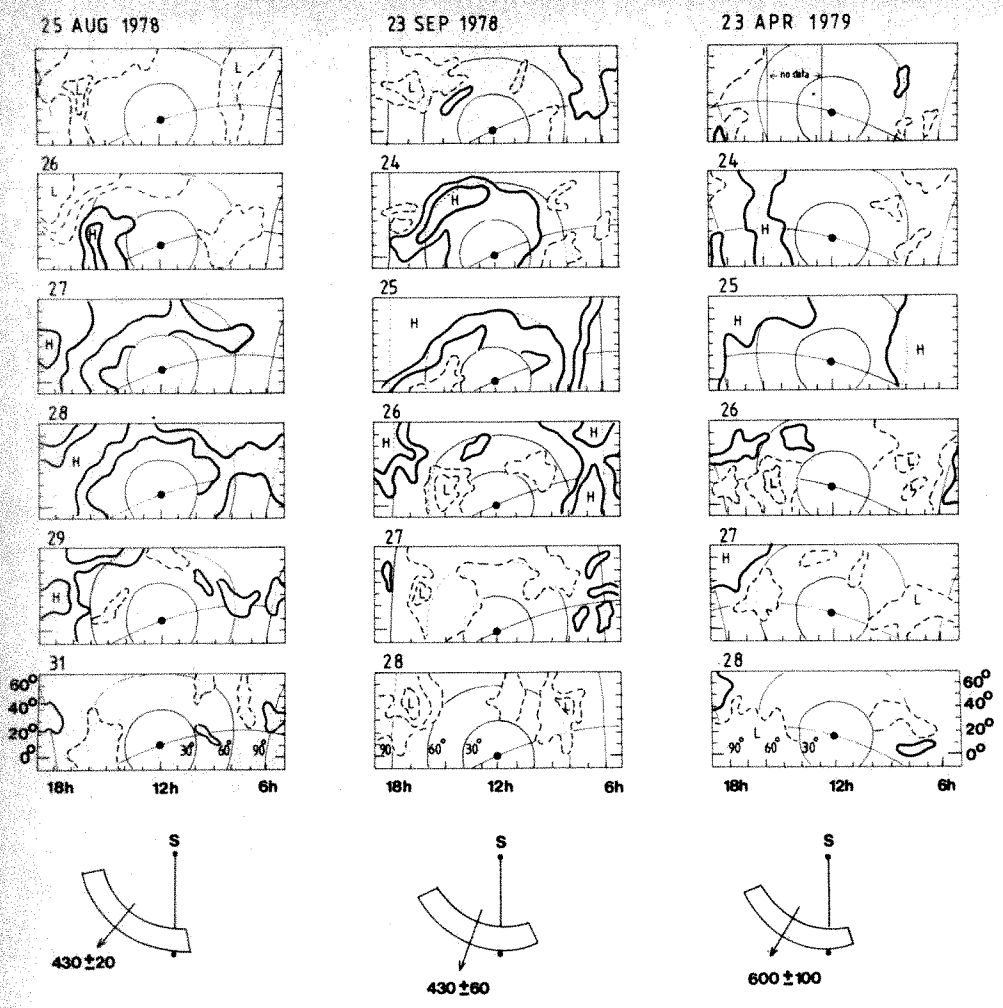

Fig. 2 Sky maps of scintillation enhancement (g) for three transients; coordinates: x, hour angle; y, declination. The contour levels for $g>1$ are 1.25, 1.5, 1.75 (heavy lines) and for $g<1$ are 1/1.25, 1/1.5, 1/1.75 (broken lines). Areas of highest (H) and lowest (L) values are indicated. Approximate shapes and speeds of enhanced density transients derived from the maps are also shown.

Fig. 2. Most of the information about transients is obtained from observations within 1 AU and so the maps have been plotted only to ±7 h from local noon. For qualitative interpretation, note that lines of sight near elongation 90° monitor disturbances as they pass the Earth. Mapping is not continued within 30° from the Sun as this is the zone of strong scattering where g is expected to show an inverse correlation with density. Significant perturbations of g are not usually observed in this region.

We have shown previously how a comparison of observed maps with theoretical maps computed for simple models of density perturbations can be used to deduce the density structure in three dimensions[4,6]. The period 1978–1979 had unusually high solar activity and most of the disturbances that we observed approximated to outward-moving spherical shells or co-rotating density structures associated with relatively long-lived high-speed solar wind streams. The approximate shapes of the enhanced density zones of the three transients are shown in Fig. 2. It is possible that the radii of curvature of the disturbances are less than indicated (although they must exceed 0.5 AU), but there is no doubt that they cover a wide range of helio-longitude and latitude. The typical solid angle is of the order $\pi/2$ sr; the precise latitude range is less easily determined and will be discussed below. The radio source grid is sufficiently fine that the outer boundaries of the transients can usually be located to an accuracy of ±5° and the day-to-day positions can then be used to estimate their speeds and arrival times at the Earth. Some other features on the maps, such as the low-density zones on 25–26 August, the structures at elongations >45° on 23 September and the high-density zone at elongation >90° on 24 April are associated with other transients or longer-lived co-rotating streams and will be described elsewhere.

Figure 3*a* shows the expected position as a function of time of the outer boundary of enhanced scintillation computed for

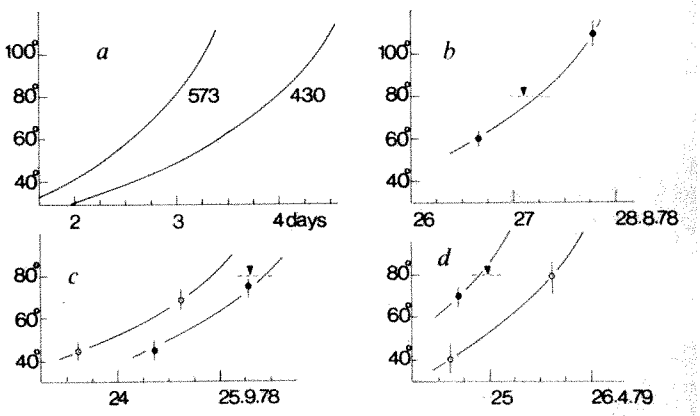

Fig. 3 *a*, Solar elongation of the outer boundary of enhanced scintillation computed for a spherical shell of enhanced density travelling at 30° to the Sun/Earth line. The starting time at the Sun is 0 days. *b*–*d*, Observed positions on the boundaries of transients. *b*, Outer boundary near the ecliptic to the east (●); *c*, outer boundary above the ecliptic (⊙) and on the ecliptic to the west (●); *d*, outer (●) and inner (⊙) boundaries near the ecliptic to the east. The times of sudden-commencement magnetic storms are indicated (▼). The curves fitted to the observations correspond to the speeds shown in Fig. 2.

a spherical shell of increased density of thickness 0.2 AU, covering a range of ±36° in helio-longitude and latitude and centred on a direction at 30° to the Sun/Earth line in the ecliptic. Constant speeds of 430 km s^{-1} and 573 km s^{-1} were assumed, corresponding to transit times of 4 and 3 days from the Sun to the Earth. The weighting of scintillation along the line of sight is such that the curves for elongations <100° are not sensitive

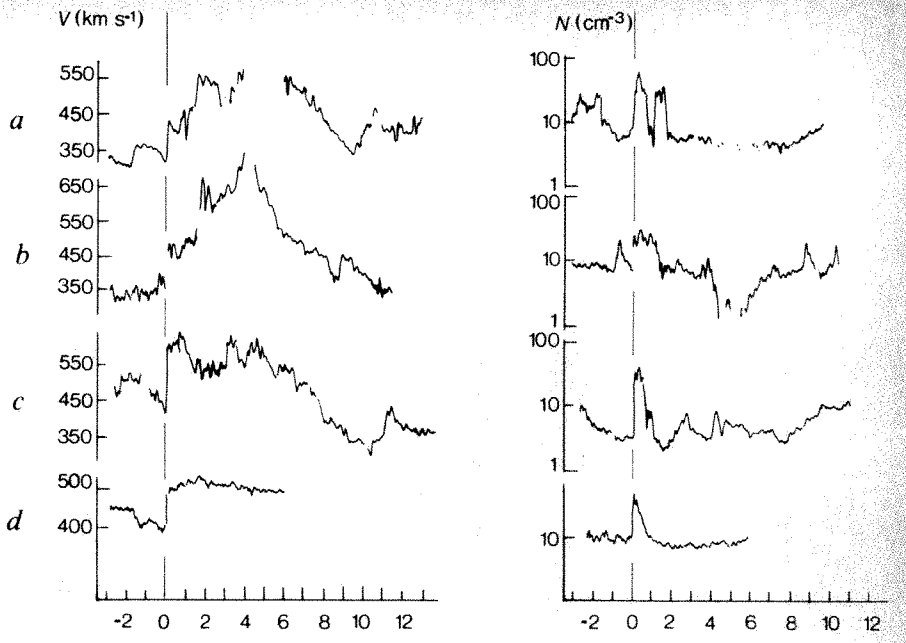

Fig. 4 The solar wind speed and plasma density observed by spacecraft near the Earth. The temporal variations are aligned with respect to the shocks (vertical line) at zero time. The arrival times are: *a*, 0300 UT, 27.8.78; *b*, 0718 UT, 25.9.78; *c*, 2357 UT, 24.4.79; *d*, a superposed epoch plot of 103 shocks observed during 1971–78.

to the direction of travel, provided that the transient is centred on a line within ~45° of the Sun/Earth line. The models indicate that the outer boundary is seen at an elongation near 80° when the transient is about to hit the Earth. Some observed positions of the boundaries of the transients mapped in Fig. 2 are plotted in Fig. 3*b–d*. The measurements refer to positions near the ecliptic, either to the east or west of the Earth. The September transient was clearly directed above the ecliptic and in this case we have also shown the location of the outermost boundary at high helio-latitude. Radio interference prevented observations of the front of the transient on 23 April and here we have made use of positions of the inner boundary. The curves fitted to the points are model curves (as in Fig. 3*a*) with suitable velocity scaling.

The times at which the transients reached 1 AU in the ecliptic are in good agreement with the onset of sudden commencement magnetic storms, indicating that the shock fronts must be close to the outer boundaries of the high-density shells causing enhanced scintillation. To complete the observations we display in Fig. 4*a–c*, the solar wind speed and plasma density observed by spacecraft close to the Earth[7] during the same periods.

Solar origin of the transients

To seek possible sources of the transients, we projected them back to the solar surface assuming transit times of 3 days for August and September and 2 days for the faster April transient. These delays are less than the 4- and 3-day transit times appropriate to our derived speeds and were chosen to allow for slight deceleration in accordance with spacecraft observations of the April event[8] for which the mean speed between 0.41 AU and 0.99 AU was 789 km s^{-1}, whereas the speed at 1 AU was 608 km s^{-1}.

The zones so defined are shown as circles on the synoptic maps in Fig. 5*a–c*. The greatest uncertainty concerns the helio-latitudes, as in two cases the maps do not extend sufficiently far below the ecliptic. It is probable that the August transient was directed slightly above the ecliptic, whereas that of April could have been below. Because this could not be confirmed they have been centred at 0°. Also shown on the synoptic maps are the outlines of coronal holes obtained from He 10,830 Å images (Solar Geophysical Data), the positions of notable solar flares or disappearing filaments discussed in connection with the same transients by other workers and the projected ranges in helio-longitude at the Sun of the high-speed streams ($V >$ 450 km s^{-1}) observed by near-Earth spacecraft[7]. The latter estimates were based on an assumed transit time of 3 days.

Figures 4 and 5 show that the shells of high density are followed by high-speed streams which originate from roughly the same zones on the Sun and subsequently persist for at least 6 days. During the September event the stream showed a further acceleration some 4 days after the initial shock. The same streams are also seen in Fig. 2, where they correspond to zones where $g < 1$, in accordance with the usual reduction of plasma density in regions of higher than average speed. Note that averaging along the line of sight in our data smooths out some of the complexity seen in spacecraft measurements at a single point and also that the density was already low before the April transient. One feature common to all the transients is that they erupted from zones containing coronal holes at moderately low helio-latitude. As it has been established that long-lived coronal holes, such as those that existed during 1974–75, are sources of relatively stable high-speed streams, we believe that our observations are most easily explained by supposing that less stable holes, typical of the ascending phase of the solar cycle[9], are the sources of variable speed flows. If the wind from such a hole increased from, say, 450 km s^{-1} to 600 km s^{-1} on any timescale shorter than ~12 h, the faster flow would catch up the slower flow ahead of it, thus generating a compression zone of enhanced density and a steepening velocity gradient which could develop into a shock at 1 AU. Theoretical modelling with reasonable velocities has demonstrated the general characteristics of the expected perturbations[10].

The same coronal hole was associated with both the August and September transients. It first appeared on Carrington Rotation 1671 and persisted for three rotations. Clouds prevented observations on 23–24 August when the transient high-speed flow should have commenced but a significant increase of area (~25%) occurred during 22–25 August (J. W. Harvey, personal communication). Such changes are fairly common and might signal increases of solar wind speed. There are two possibilities for the source of the April transient which has been associated previously[8] with the disappearing filament shown in Fig. 5*c*: (1) the hole at longitude 30° and latitude 25°N; (2) the complex hole structure in the Southern Hemisphere. On the following rotation (CR 1681) a large hole at similar longitude extended upwards from the southern pole to latitude 15°S following the tendency for mid-latitude holes to merge with holes at higher latitudes as they overtake them under differential rotation[9]. Coronal hole activity in the south is the most probable source of the transient.

Precise alignment of the projected zones of origin with coronal holes is not expected. High-speed streams at 1 AU typically extend over wider ranges of longitude than those of the hole

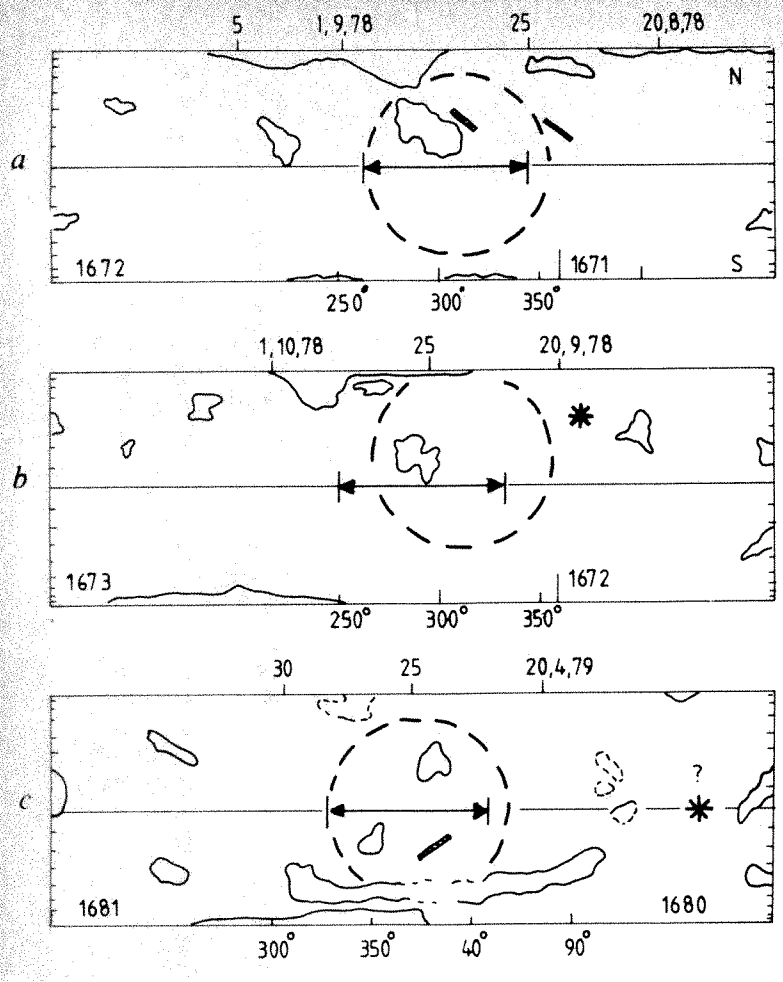

Fig. 5 Predicted areas (dashed circles) from which three transients erupted plotted on synoptic maps showing the boundaries of coronal holes obtained from He 10,830-Å images. Arrowed zones on the Equator denote the predicted longitude range of high-speed streams of speed ≥450-km s^{-1}. Date marks correspond to CMP at 0000 UT. The locations of flares (stars) and disappearing filaments are indicated.

boundaries seen in the He 10,830-Å images and little is known about the divergence of streams near the Sun. Again, the co-rotation of transient high-speed streams after their eruption will generate enhanced density at the western edges of the streams[11]; this could account for the small (and possibly insignificant) systematic westerly displacement of the high-density zones with respect to the streams seen in Fig. 5.

Sudden disappearances of solar filaments have been associated with the transients of August and April and their positions are shown in Fig. 5 (refs 8, 12 and J. W. Harvey, personal communication). Both the timing and location of these events are consistent with our observations; it is reasonable to speculate that large-scale disturbances of the solar wind will be accompanied by major changes in the coronal magnetic field that could destabilize the filaments.

Solar flares have also been associated with two of the transients[13] although that for the April event was later discounted[14]. Our observations disagree with the suggested flare-source for the September transient, shown in Fig. 5*b*, where there is a large discrepancy in position and the timing is also inconsistent. The flare occurred at 0940 UT on 23 September while the outer boundary of the transient was observed at a distance of 0.7 AU at 1500 UT on the same day. If the flare triggered the disturbance, the average speed must have been ~7,000 km s^{-1}, which is unreasonably high.

We discussed previously another flare discrepancy[3] and our observations during 1978–81 contain further examples, raising the question of whether flares are as effective in causing shock-disturbances at 1 AU as is sometimes assumed[13]. Figure 4*d* shows a superposed epoch plot of 103 shock events at 1 AU, the sample constituting all the shocks observed during 1971–78 on the IMP 6, 7, 8 spacecraft[15]. The average properties are very similar, though less extreme, than the major transients we have described. In particular, the high-speed flow behind the shocks lasts, on average, for 5–6 days. Both the duration of the flows and the slow increase of velocity to a peak 1–2 days after shock passage are more similar to the behaviour of transient solar wind streams than to the expected properties of shocks induced by the sudden release of large amounts of energy in the lower corona[16]. In the latter case, models predict a swifter return to ambient conditions.

The new cause that we suggest for major disturbances does not eliminate the possibility of correlations between flares and shocks at 1 AU. It is probable that the emergence of more energetic solar wind flows is accompanied by changes in the coronal magnetic field structure which could trigger a variety of sudden events in the solar atmosphere including flares and eruptive prominences. But these would be peripheral to the main disturbance. The important aspect of our theory concerns the primary source of energy for large-scale interplanetary transients. This we identify with the mechanism that accelerates high-speed streams and not with the impulsive release of magnetic free energy in the chromosphere and the corona.

Fractal growth of viscous fingers: quantitative characterization of a fluid instability phenomenon

Johann Nittmann*, Gérard Daccord* & H. Eugene Stanley†

* Etudes et Fabrication Dowell Schlumberger 42003 St Etienne, France

What happens when one attempts to push water through a fluid of higher viscosity? Under appropriate experimental conditions, the water breaks through in the form of highly branched patterns called viscous fingers. Water was used to push a more viscous but miscible, non-newtonian fluid in a Hele-Shaw cell. The resulting viscous finger instability was found to be a fractal growth phenomenon. Reproducible values of the fractal dimension d_f were found and were interpreted using a modification of the diffusion limited aggregation model.

WHEN one attempts to use a low viscosity fluid (like water) to push high viscosity fluid (like oil), there arises a fluid instability phenomenon termed the 'viscous fingering instability' in which the low viscosity fluid forms characteristic fingers extending well into the high viscosity fluid[1-4]. In addition to its obvious interest in enhanced oil recovery by water flooding, and other practical applications, this phenomenon is of considerable basic interest and is not understood at present. It may be studied in detail in the laboratory using a Hele-Shaw cell, which is a pair of transparent plates separated by typically 0.5 mm. The space between the plates is filled with high viscosity fluid and the low viscosity fluid is injected. Normally, the interfacial tension between the two fluids is high and the low viscosity fluid forms non-fractal patterns that resemble the fingers of a glove[1,2]. Fractal phenomena are found to be associated with a range of random systems[5-8]. For this reason it is of interest to inquire whether or not there exist experimental conditions under which viscous fingers obey a fractal symmetry.

Experiments

Fractal structures in nature typically occur when randomizing effects dominate over stabilizing effects. Hence to find a fractal structure we must eliminate stabilizing effects so that the randomness can dominate a structure. To this end we shall minimize the role of interfacial tension[1,2] as well as intermolecular diffusion[3]. Therefore, we chose a viscous fluid with zero interfacial tension against water, an aqueous polymer solution of high relative molecular mass polysaccharide for which the mixing time is very slow compared with the time of the experiment.

Since the viscosity difference is the driving force for the instability, a high viscosity is desirable. Hence we use a non-newtonian fluid: the low-shear regions have high viscosity while the shear thinning character of the fluid makes it easy to pump it through the narrow gap of the Hele-Shaw cell without causing

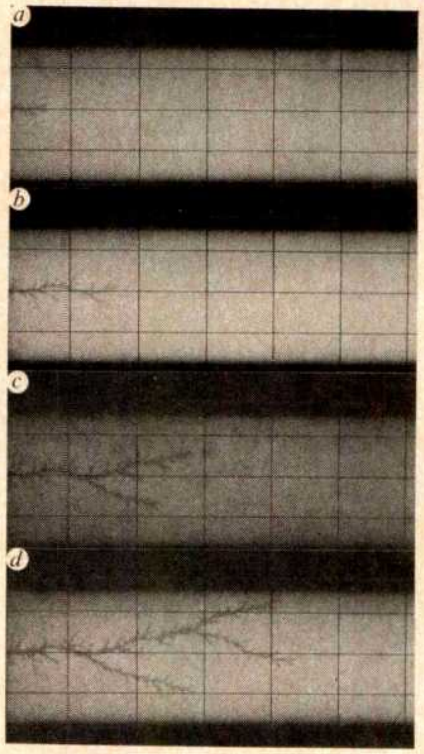

Fig. 1 Typical viscous finger created by water advancing into a Hele-Shaw cell filled with a non-newtonian fluid with zero interfacial tension (experimental conditions described in the text). The time interval between successive photographs is typically 5 s. The grid rectangles have dimensions 3 cm × 5 cm. The water, dyed with methylene blue, is injected under force from a single inlet on the left wall into an aqueous polymer solution whose viscosity varies between 10^3 and 10^4 cP depending on the water velocity.

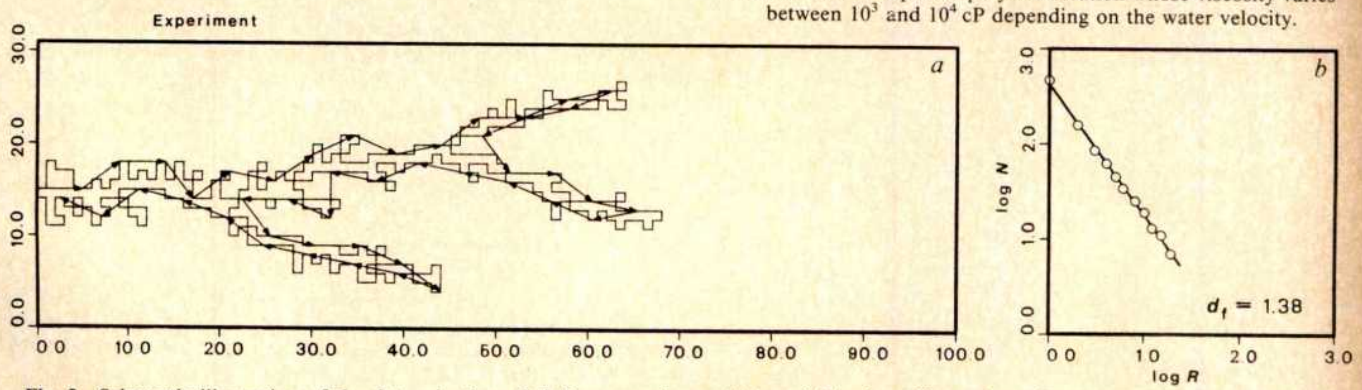

Fig. 2 Schematic illustration of the determination of d_f from experimental data of Fig. 1. *a*, Illustration of how the contour length of the digitized finger is measured with a ruler of length $R = 5$. *b*, The slope of the straight line gives $-d_f$, from which we find $d_f = 1.39$.

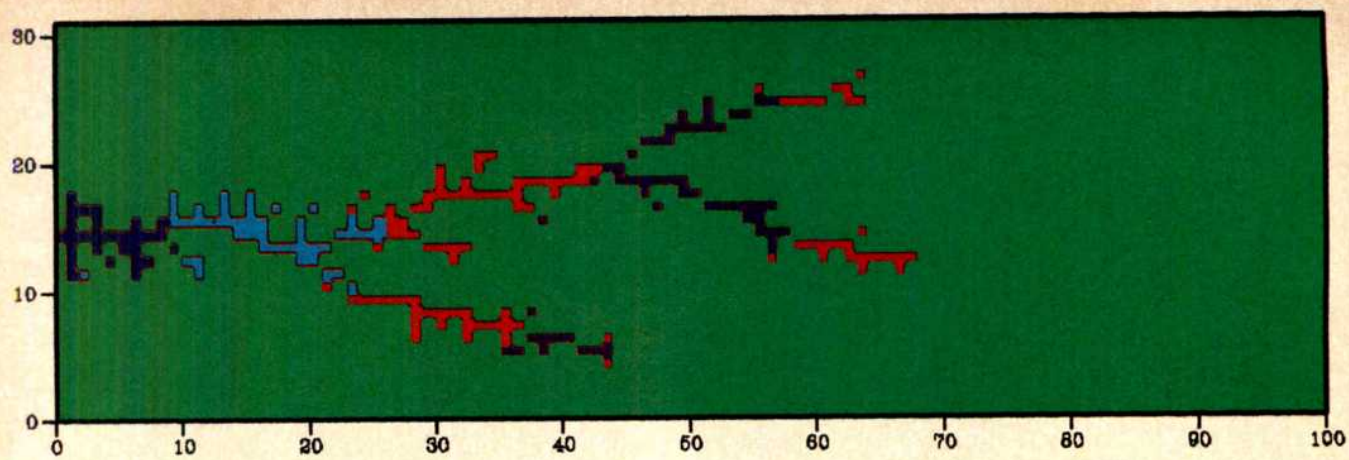

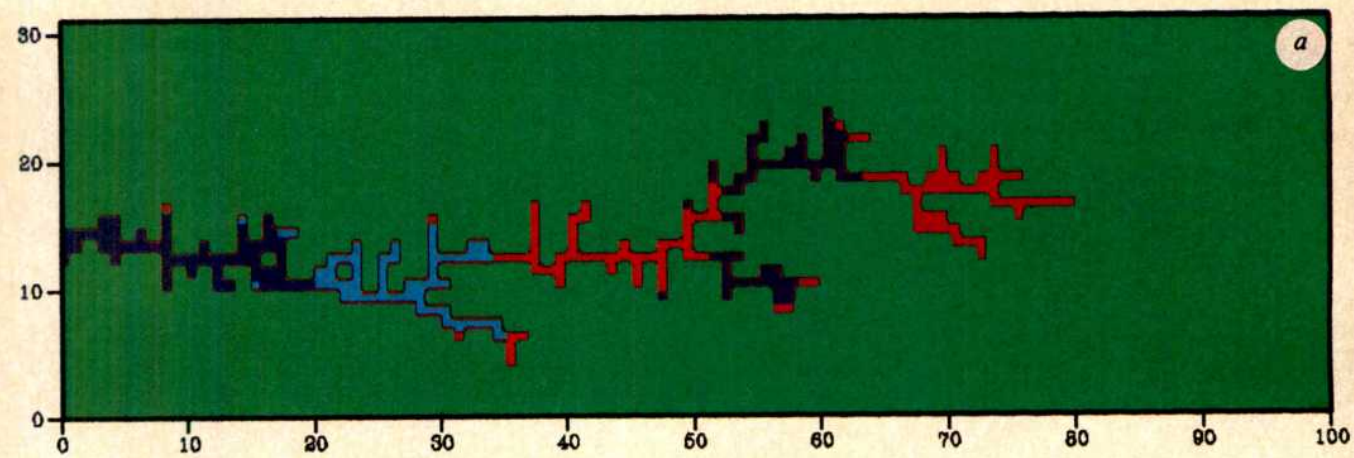

Fig. 3 Digitized representation of the viscous finger of Fig. 1. The colour coding is an indication of the time evolution of the instability, the order being dark blue, light blue, red, violet and pink. The colour coding is for comparison with the model calculations of Fig. 4.

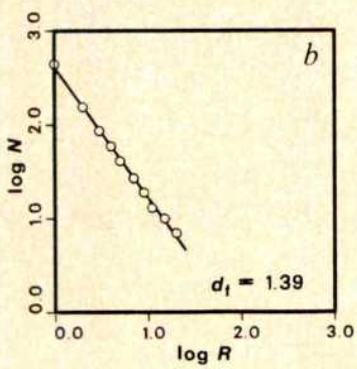

Fig. 4 Results of model calculation for the ratio $W_{HS}/W_f = 30$, corresponding to the experiments of Fig. 1. *a*, Colour coding indicates the time of arrival of the random walker, the order being dark blue, light blue, red, violet and pink; each colour represents 20% of total time. Comparison with Fig. 3 confirms the agreement between experiment and the model. *b*, The fractal dimension of the aggregate shown is 1.39, in agreement with the analysis of the experimental data of Fig. 2.

bending of the plates. In contrast, tests with newtonian fluids were limited to a viscosity of 100× that of water, and steady fine-structured fingering patterns were not observed.

We placed the polymer solution into a perpex Hele-Shaw cell[8] of thickness 0.5 mm, length 0.9 m and width 0.1 m. Water dyed with methylene blue was injected at one end at a variety of flow rates between 0.4 and 40 ml min^{-1}. We used three different polysaccharides and have varied the polymer concentration from 0.24 to 1.2 wt %. The viscosity of the polymer solution varies between 10^3 and 10^4 cP depending on the water velocity. We have also repeated measurements using a Hele-Shaw cell of thickness 1.0 mm. The resulting viscous finger patterns were random and highly branched (Fig. 1, *a*–*d*).

Analysis

Visual examination of these patterns reveals the striking presence of structure at many different length scales. Hence it seemed appropriate to attempt to analyse the structure of a viscous finger using the concept of self-similarity or fractals[5]. To this end, we first digitized the fingering patterns (Fig. 3) using a pixel size equal to the characteristic thickness of a viscous finger. We then analysed the patterns as follows. We measured the total exterior perimeter length using a 'ruler' of length $R = 1$, measured in units of a pixel. Then we repeated the same operation for a range of increasing R values up to $R = 20$ (Fig. 2*a*). The apparent length of any fractal, in units of R, decreases as R^{-d_f} (Fig. 2*b*)[5,9]. The d_f of the external perimeter is the same as the d_f of the total mass if loops do not occur on all length scales[5]. We find the quantitative parameter, $d_f = 1.40 \pm 0.04$, which characterizes viscous fingers for a wide range of polysaccharides, polymer concentrations and water flow rates, suggesting that viscous fingers indeed have a reproducible and universal fractal dimension.

As a second method, we placed an imaginary box of edge L on each point of the finger. For each box, we counted the number of points (the total mass) inside the box. As L increases, this mass should scale as L^{d_f} if the finger has a fractal structure[10]. We find that Method 2 gives smaller values for d_f than predicted by Method 1. The difference is ~8 % and is explained by the fact that a large proportion of the finger points lie on the

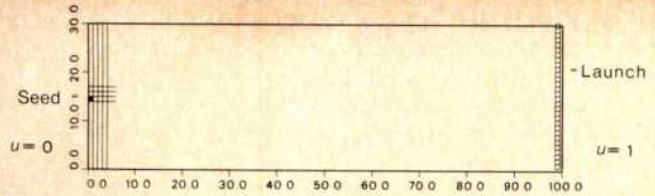

Fig. 5 The basic geometry of the generalized Witten-Sander model used to simulate viscous fingers. Random walkers are released from a randomly chosen point on the right wall, and 'die' if they strike the lateral or end walls.

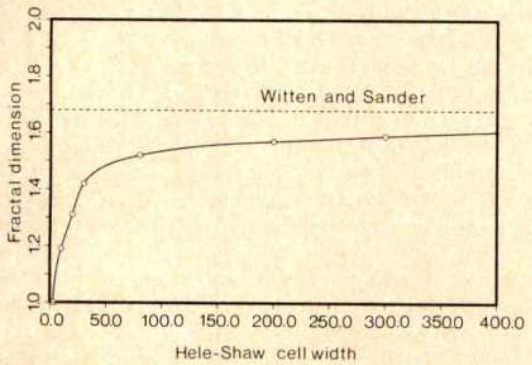

Fig. 6 Dependence on W_{HS} of the apparent value of the fractal dimension, d_f.

perimeter of a particular pattern and boxes centred at these points will cover much unoccupied area outside the structure. For the large-scale numerical simulations discussed below, the number of points on the perimeter is small compared with the total number of points; both methods give identical fractal dimensions.

Statistical model

The mean velocity, v, of a viscous fluid in a Hele-Shaw cell is given by the gradient of a potential $\phi = -(b^2/12\,\mu)\,P$, where b is the plate separation, μ is the shear viscosity and P is the fluid pressure[11]. For incompressible fluids, div $v = 0$; hence we obtain a Laplace equation for the potential distribution

$$\nabla^2\phi = 0 \qquad (1)$$

If, as in our case, the viscosity ratio between the two fluids is very large, we can approximate the potential in the less viscous fluid to be a constant ($\phi = \phi_0$). At the outlet, ϕ takes on a different value $\phi = \phi_1$.

With these boundary conditions, equation (1) is identical to the Laplace equation describing the probability $u(r, t)$ of a random walker to be at the point r at the time t[12,13]. This is similar to diffusion-limited aggregation (DLA)[13–16], so we propose the following quantitative model for viscous fingering. Place a seed particle at the origin (Fig. 5) and release a random walker from a randomly chosen point on the opposite wall. If the random walker hits the seed, it sticks, whereas if it hits any of the four walls, it 'dies' and a new walker is released. For the simulation, we have chosen our 'Hele-Shaw' cell width $W_{HS} = 30$ (in units of a lattice constant), as the experimental value of $x = W_{HS}/W_f$ is ~30, with W_f the characteristic size of a single finger. Formally, the probability $u(r, t)$ can be mapped onto the fluid potential $\phi(r, t)$ described above, $u(r, t) = (\phi - \phi_0)/(\phi_1 - \phi_0)$. Thus, $\phi - \phi_0$ in the finger corresponds to $u = 0$ in the aggregate, whereas $\phi = \phi_1$ at the outlet maps to $u = 1$ at the source of random walkers.

Two striking features of the actual viscous finger experiments are mirrored by our statistical model. The first of these is the tendency of a growing side branch to die out after a relatively short period of growth. The second is the fact that the entire viscous finger strongly avoids coming even moderately close to the lateral walls of the Hele-Shaw cell. Both effects are seen

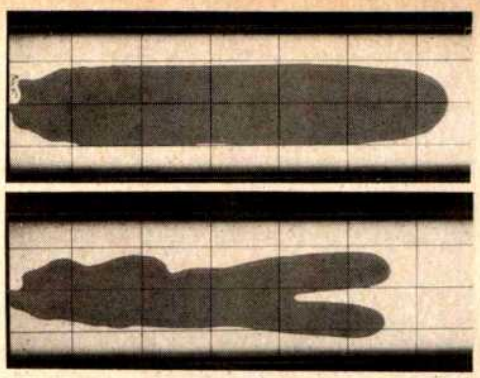

Fig. 7 A viscous finger created by water advancing into a Hele-Shaw cell filled with a newtonian fluid, oil. Two different capillarity numbers are used: *a*, $N_{ca} = 0.08$; *b*, $N_{ca} = 0.16$.

clearly in the model and arise from a common source, 'screening'[13–16]. This screening can be understood as follows. A random walk, statistically speaking, sticks to the tips of the growing aggregate so that the main trunk of the aggregate effectively shields the smaller side fingers. As the lateral walls absorb the random walkers, they act as 'ghost fingers': the viscous finger and the wall together form an essentially impenetrable deep fjord. This can be seen dramatically by the colour coding of Fig. 4, where the last random walkers to arrive, coloured pink, rarely reach the side fingers and never penetrate the deep fjord between the aggregate and the wall.

Calculating d_f as described above, we find $d_f = 1.41 \pm 0.05$ (see Fig. 5), a value remarkably close to the experimental value but considerably different from the value $d_f = 1.68 \pm 0.04$ for DLA[17]. Could this difference arise from the geometric constraint of the lateral walls? To test this possibility, we made additional simulations for a range of values of x. We find (Fig. 6) that the apparent value of d_f increases smoothly from $d_f \cong 1$ (for $x \cong 1$) to $d_f \cong 1.60$ (for $x \cong 10^3$). To check this prediction, we also performed experiments for a Hele-Shaw cell half as wide ($x = 15$) and find that $d_f = 1.12 \pm 0.04$, consistent with the predicted value of Fig. 6. What is the source of this apparent dependence of d_f on W_{HS}? At first sight, one might be tempted by an analogy with a growing polymer chain in the same confining geometry; it takes on the bulk value of d_f until it has grown sufficiently to sense the presence of the lateral walls. However, our problem is quite different, since the lateral walls strongly influence even the initial stages of finger growth because the incoming random walks are strongly influenced by the absorbing lateral and end walls. Hence the small fingers cannot capture enough mass to achieve the full DLA structure (this fact becomes especially clear if we consider very small values of W_{HS}). So while for the polymer problem d_f crosses over directly from its bulk value to its ultimate value of $d_f = 1.0$, for the Hele-Shaw fingering problem d_f never takes on its bulk value but instead takes on a smaller value that depends monotonically on W_{HS} (Fig. 6), crossing over ultimately to $d_f = 1$ when $R \gg W_{HS}$.

Discussion

We consider here the relation of the present experiments to previous work on viscous fingering. The classic Saffman–Taylor work did not produce ramified fractal structures. To obtain fine-structured instability patterns for an immiscible fluid system, the critical wavelength λ_c of a perturbation[2,18], defined as $\lambda_c = k[b^2/(12\,N_{ca})]^{1/2}$ has to be much smaller than W_{HS}. N_{ca} is the capillarity number, defined as $N_{ca} = \mu v/\sigma$ (σ is the interfacial tension) and corresponding to the ratio of viscous forces to capillarity forces: k is a dimensionless parameter that depends on the contact angle between the two fluids and the plates (wettability)[18]. We have also performed Saffman–Taylor type experiments with an immiscible newtonian oil–water system with varying flow velocity v, and Fig. 7 indicates that a change

in the flow condition from $N_{ca} = 0.08$ to 0.16 introduces a bifurcation into fingers when the finger thickness exceeds twice λ_c[19]. A continuation of this process would presumably create smaller and smaller fingers with a tree-like structure, but would require a further increase in the capillarity number or a decrease of the plate distance b. We cannot test the possibility that newtonian fluids with very low interfacial tension and negligible intermolecular diffusion but with a very high viscosity ratio, might give rise to similar fractal instability patterns, as our experiments were limited by the finite strength of the cell. By using water and a non-newtonian water-based fluid, we obtained a flow with an infinite capillarity number and a high viscosity ratio in regions where shear stresses are low. We believe both aspects are important and explain the difference from the Saffman–Taylor results.

Our present findings can be applied to the basic physics underlying petroleum science[4,20]. In the traditional '5-spot well configuration', four production wells are drilled at the corners of a large square and CO_2 (or a low viscosity fluid with a very low interfacial tension with oil) is then pumped into a fifth injection well in the centre. The CO_2 plays the role of the water in our model experiments, whereas the oil is analogous to the polymer solution. Large-scale viscous fingering phenomena not bounded by the walls of a Hele-Shaw cell occur and drastically reduce the efficiency of the oil recovery. The observed viscous fingers are quasi-two-dimensional as the thickness of the rock formation is typically several orders of magnitude less than the separation of the injection and production wells. It is therefore customary to assume that the patterns observed in the quasi-two-dimensional Hele-Shaw cells are relevant to the observed macroscopic phenomena. The similarity in the mathematical description of flow through porous media and the Hele-Shaw cell have been observed previously[1]. Thus, our experiments and model calculations strongly suggest that the viscous fingers observed in a 5-spot pattern are rich geometrical structures possessing a scale-invariant symmetry and quantitatively characterized by a fractal dimensionality.

Conclusion

There is no complete theory of miscible viscous fingering, perhaps because there was no quantitative parameter to characterize viscous fingers. Here, we find that viscous fingers are fractals and that their many different random structures have the identical value of the fractal dimensionality. This suggests that the physical basis of the viscous fingering instability is analogous to that of other second-order phase transitions that obey the same sort of scale invariant symmetry found here for viscous fingers[21]. Recent work supports our point of view: quasi-two-dimensional dielectric breakdown seems to exhibit the same sort of fractal structure that we find for the viscous fingering instability[22]. That these two breakdown phenomena should be related is plausible in light of the parallels in the equations describing them[23].

We thank R. Lemanczyk, P. Rossi and the management of Dowell Schlumberger for their encouragement during this work. The Center for Polymer Studies is supported by grants from NSF and ONR. We also thank F. Leyvraz, P. Meakin and J. D. Sherwood for helpful discussions.

Note added in proof: Since acceptance of this article, we have learned of independent work on viscous fingering, both from the experimental (ref. 24, and L. M. Sander and E. Ben-Jacob, personal communication) and theoretical[25,26] points of view.

LETTERS TO NATURE

A very bright water vapour maser source in the galaxy NGC3079

Aubrey D. Haschick* & Willem A. Baan†

* Haystack Observatory, Massachusetts Institute of Technology, Westford, Massachusetts 01886, USA
† Arecibo Observatory, Arecibo, Puerto Rico 00612

The 6_{16}–5_{23} transition of water vapour at 22.235080 GHz has been found in our Galaxy to be associated with regions of young star formation[1,2]. H_2O maser emission was detected initially in an external galaxy by Churchwell *et al.*[3]. To extend the range of detected properties of 'star burst' galaxies (galaxies showing an enhanced star formation from their optical spectra) we undertook an initial survey for H_2O maser emission in this type of galaxy, but with negative results. Here we report on the subsequent extension of this survey to spiral galaxies displaying continuum radio emission, which is also an indication of star formation activity. We have detected the most luminous H_2O maser source yet reported, ~500 L_0, in the galaxy NGC3079. OH absorption was also detected in this galaxy and we suggest that maser amplification of the nuclear radio source causes the observable H_2O emission.

The 30 galaxies for the survey reported here were selected from lists[4,5] of bright spiral galaxies containing radio sources having both compact and extended components. The observations were carried out in March, April and May 1984 using the 37-m radio telescope of Haystack Observatory, equipped with a maser receiver and a 1,024 channel digital auto-correlator. The system temperature is ~90 K and the bandwidths 20 and 40 MHz, providing resolutions of 0.8 and 3.2 km s^{-1}, respectively, at the rest frequency of 22.235080 GHz. Each source was observed in the total power mode for 3 h; the antenna beam is 90 arc s and covers only the central part of each galaxy.

In Fig. 1 is a spectrum for NGC3079 showing a strong central water vapour feature of ~5 Jy in size and having a width of ~10 km s^{-1}; in addition, there are weaker emission features of <1 Jy extending out to velocities of ±80 km s^{-1} from the central feature. The strongest feature in NGC3079 is blueshifted by ~200 km s^{-1} from the systemic velocity of the galaxy of 1,171 km s^{-1} (ref. 6). In Fig. 2 is a spectrum (taken on the NRAO 300-ft telescope in May 1984) of the absorption by the OH radical at 1667.358 MHz in the radio continuum of NGC3079 (see also B. Turner, I. Kazes and L. J. Rickard, personal communication). This spectrum shows a deep absorption feature ($N_{OH}/T_{EX} = 7.6 \times 10^{15}$ cm^{-2} K^{-1}) at lower velocities than the systemic velocity of the galaxy. The velocity of the H_2O maser emission is indicated lying on the blueshifted edge of the OH absorption, implying that the H_2O maser source is foreground

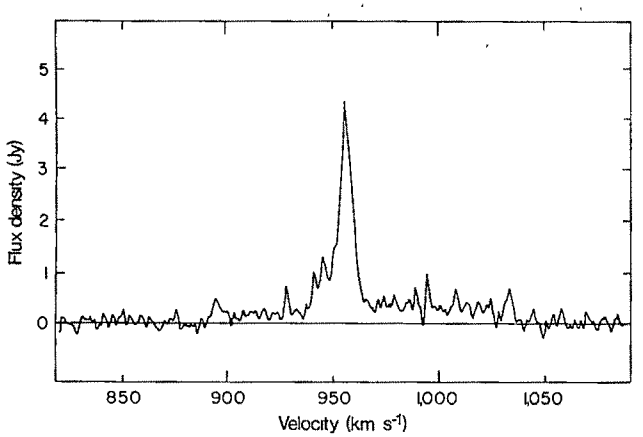

Fig. 1 A spectrum of NGC3079. The rest frequency is 22.235080 GHz and the resolution is 1.3 km s^{-1}. Velocity is given by $c\Delta\lambda/\lambda_0$, where c is the velocity of light and λ, the wavelength.

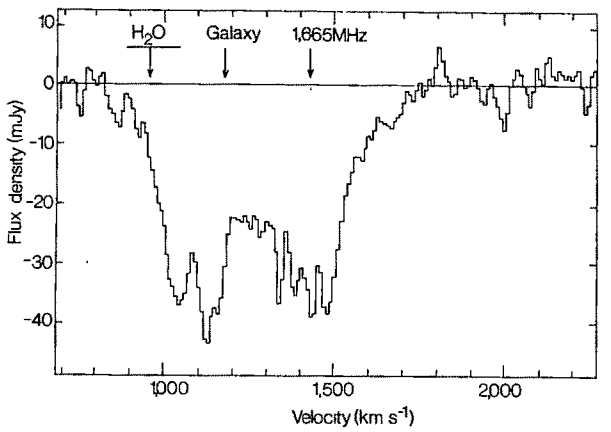

Fig. 2 An OH spectrum of NGC3079 taken on the NRAO 300 ft antenna in Greenbank, West Virginia. The rest frequency used is 1,667.358 MHz. Also indicated on the plot are the velocities of the H_2O maser source and the 1,665 MHz absorption feature. The 1,665 and 1,667-MHz absorption features are slightly blended. The galaxy velocity is also indicated. This absorption feature has been independently detected by Turner, Kazes and Rickard (personal communication).

to the radio source. It is likely to be close to the nucleus and part of an outflow of gas from the galaxy nucleus.

The H_2O spectrum of NGC4258 is given in Fig. 3 and shows a significant change from that given by Claussen, Heiligman and Lo[7] for January 1983 in that a feature at 455 km s^{-1} has risen to a level of ~10 Jy. Spectra taken in August 1984 (G. Garay, J. M. Moran and A.D.H., unpublished results) show this feature to have declined to ~5 Jy. As the weak feature at ~490 km s^{-1} is approximately the same amplitude of ~1.5 Jy in the January 1983 spectrum as in April 1984, it may be constant, with the difference in shape being attributable possibly to the poorer signal/noise ratio of the later spectrum. The linear polarization of the brightest velocity features in the maser sources in NGC3079 and NGC4258 was measured (G. Garay, J. M. Moran and A.D.H., unpublished results) using the Haystack antenna and found to be <6% for NGC3079 and <2% for NGC4258. The non-detections of galaxies are listed in Table 1 together with their upper limits.

The maser source in NGC3079 is the most luminous maser source yet detected having a peak isotropic luminosity in June 1984 of ~500 L_0, assuming a distance to NGC3079 of 16.5 Mpc ($H_0 = 75$ km s^{-1} Mpc^{-1}). NGC3079 and the previously detected galaxies NGC4258 (130 L_0, this observation) NGC1068[7] (350 L_0), NGC4945[8] (240 L_0)[9] and the Circinus Galaxy[10] (37 L_0), form a class of galaxies that contain highly luminous water vapour maser emission. For comparison, in our own

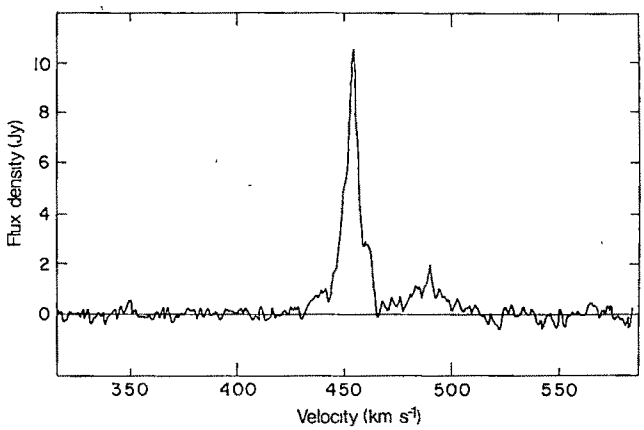

Fig. 3 A spectrum of NGC4258. The resolution and rest frequency are as in Fig. 1.

Galaxy the strongest source known, W49N, has a luminosity of <1 L_0 and all other extragalactic water vapour masers detected thus far are <L_0.

One interpretation[7] for the high luminosities of the H_2O maser sources in these galaxies is that they could indicate a burst of star formation of 10^5–10^6 stars assuming that the maser emission is the sum of a number of individual sources and considering that the H_2O luminosity of an average star formation region in our galaxy is 10^{-3} L_0. This is similar to the burst of star formation of ~10^8 stars that would be predicted from a comparison of luminosities of the bright OH maser emission detected by Baan, Wood and Haschick[11] in the galaxy IC4553 (Arp 220).

An alternative explanation for these bright maser sources may lie in the supposition that we are seeing low-gain maser amplification of the background continuum radio source. A salient characteristic of these five galaxies is the presence of nuclear radio sources in all cases[5,8,9]. In the example of the OH megamaser IC4553, the emission is found to be exactly superimposed

on the nuclear radio source, which is resolved into three components; relatively low-grain maser amplification of the background source is suggested as being the mechanism for producing the intense OH-maser emission (ref. 12 and R. P. Norris, W.A.B, A.D.H., R. S. Booth and P. J. Diamond, in preparation), even though the masing region in front of the central component may be partially saturated. This indeed may also be the mechanism producing the intense H_2O emission in the above mentioned galaxies. Recent Very Large Array observations with a resolution of 2.5 arc s indicate that the brightest feature in NGC3079 is superimposed on the compact nuclear radio source. Furthermore M. J. Claussen *et al.* (personal communication) report that the strong maser feature in NGC1068 is coincident with one of the three radio-continuum knots in the nucleus of the galaxy and that the H_2O features in NGC4258 are coincident with the nuclear radio source in this galaxy. These positional coincidences may be characteristic of the emission mechanism responsible for the H_2O lines. The narrower H_2O velocity features, $\sim 10\,km\,s^{-1}$ for the main features seen in these galaxies, as compared with 108 $km\,s^{-1}$ in IC4553, would indicate higher-gain amplification by fewer H_2O masing regions than in the OH example and a smaller size for the H_2O sources. The brightness temperature of the H_2O features in NGC3079 will determine whether the amplification hypothesis is applicable in this case. However, a molecular region with an inverted H_2O population will amplify radiation from a background continuum source until the maser reaches saturation and is observable; without the background source the maser may be weaker or not observable.

Maser amplification of the background continuum would not eliminate the necessity for highly luminous pump sources for the masing regions and it is possible to postulate that bursts of star formation supply the energy for these maser sources. All the powerful extragalactic masers are associated with galaxies having both a high infrared luminosity, which is thought to indicate a large number of hot massive stars enshrouded by dust and signs of nuclear activity. Galactic H_2O maser sources are thought to be pumped collisionally[13], but as these extragalactic amplifying masers could be only partially saturated, the pump source may be radiative requiring only a modest burst of star formation ($<10^3$ stars) Pump models as suggested by Strelnitzkij[14] could present further alternatives to explain the luminous maser emission.

It also seems pertinent that three of the five luminous masing galaxies are edge-on galaxies (NGC1068 and the Circinus galaxy being the two exceptions), which raises the molecular column density and thus the probability of having H_2O masing regions on the line of sight to the nuclear radio source. The presence of OH absorption in two of the galaxies (NGC3079 (see Fig. 3 and B. Turner, I. Kazes and L. J. Rickard, personal communication) and NGC4945; ref. 15) indicates the presence along the line of sight of dense molecular clouds. The relatively large number of non-detections of strong H_2O maser sources in galaxies having radio continua would imply that the presence of a nuclear radio source is a necessary, but not sufficient, condition for this maser emission. Thus, it seems plausible that these superluminous extragalactic maser sources may simply comprise a number of individual masing regions which are foreground to the nuclear radio source.

Periodicity in the BL Lac object OJ287

L. Carrasco, D. Dultzin-Hacyan & I. Cruz-Gonzalez

Instituto de Astronomia, National University of Mexico, Apartado Postal 70-264, Mexico D F 04510, Mexico

Short-term variations in luminosity provide the best upper limits for the sizes of active galactic nuclei. Periodicity provides further information on the geometrical, dynamical and physical models of these regions. The best candidates for the study of such variations are the so-called blazars (optically violently variable (OVV) objects and BL Lac objects). Our photometric observations of OJ287 reveal periodic variability in timescales of a few minutes. We conclude that our results are compatible with the presence of 'hotspots' in a thick accretion disk spiraling into a Kerr's supermassive black hole and that the central source is seen nearly pole-on.

The highly variable nature of OJ287 at visible, radio and infrared wavelengths is well established[1,2]. However, the possibility of periodic light changes in this object has created some controversy[3–5]. Recent observations[6] at radio wavelengths (22 and 37 GHz) seem to indicate that OJ287 could vary regularly with a periodicity of 15.7 min. We have undertaken an observational program to search for regular time variations in the light of blazars, looking particularly at OJ287 as a promising candidate. The light curve of OJ287 has been observed with a 1-s time resolution, during eight night runs collected between January and March 1983, with two additional runs in February 1984. Table 1 summarizes the dates and duration of the observations. The observations were carried out using a high-speed two-channel photometer, developed by Nather[7], attached to the 1-m telescope at Tonantzintla Observatory. To maximize the photon counting rate, the observations were carried out without filter, using the full spectral response of the photomultiplier (RCA 8850) which yields an instrumental effective wavelength similar to that of Johnson's B band. This two-channel photometer allows simultaneous observations to be made of comparison sources, so enabling fluctuations in atmospheric transmission and extinction to be removed from the observed light curves. From photometry done through several apertures, we find that 99% of the light was contained within 15 arc s. To eliminate instrumental modulation, we chose a 29-arc s diaphragm. We applied the same observational and reduction techniques to stellar objects to determine the instrumental effects;

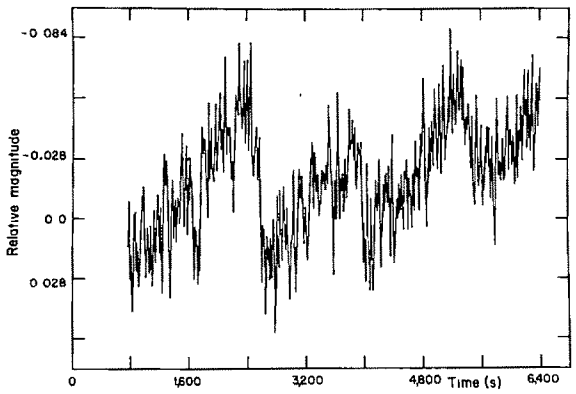

Fig. 1 Observed light curve for the night of 10 March 1983. $t=0$ corresponds to 2h 51.7 min (UT).

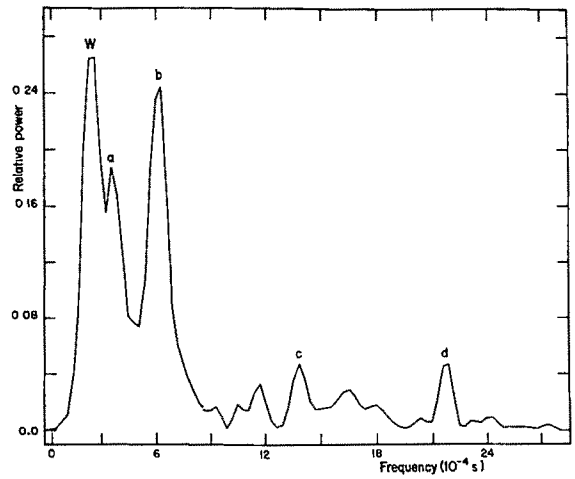

Fig. 2 Power spectrum derived from Fourier analysis with the Deeming algorithm for unevenly spaced points, applied to the 1983 data. Feature W corresponds to the observational time window. Features a, b, c and d are produced by the intrinsic shape of the light curve of OJ287 The corresponding periods are listed in Table 2

none were found that affected our conclusion regarding the periodicity of OJ287.

A typical corrected light curve of OJ287 during the 1983 active period is shown in Fig. 1. The periodicity of the light variations indicates a period of 23 min. Furthermore, a fast Fourier transform analysis of the time series has been performed on the individual runs and on all the observations carried out in 1983. For the latter, the Deeming[8] algorithm was used on zeroed and edge-smoothed data. In every case, we find significant power at the frequencies corresponding to the periods listed in Table 2 (see also Fig. 2). Our analysis implies that the detected light variations are coherent over at least the two months in 1983 during which the observations were carried out. The active period of OJ287 could have lasted a year, or be present again at the beginning of 1984, when the observations were repeated and the same results obtained. Note that the most evident frequency present in our data set is roughly double the frequency detected during the 1972 active period of OJ287.

From the Fourier analysis of individual nights, a little power at the fundamental frequency of the gear's periodicity was seen, corresponding to a period of 138 s The amplitude for the 23-min period, the most prominent one during the observation, was 0.030 ± 0.005 m. From the apparent magnitude of the object ($m_v\sim12$) at those times and a redshift $z=0.301$ (ref. 9), we obtain 4×10^{45} erg s^{-1} for the visible luminosity of the modulated component.

Note that at the epoch of our observations (1983–84), OJ287 was at maximum brightness ($m_v\sim12$), which was also the case 10 years ago when Visvanathan and Elliot[3] reported light variations with a 40-min period, which were confirmed a year later by Frohlich *et al.*[4]. On careful examination of the light curve in ref. 3, however, a period of ~20 min cannot be excluded.

One way in which short-period variations could be produced involves the pulsational modes of self-gravitating accretion disks around supermassive black holes[10]. Grauer[11] suggested that quasiperiodic optical variations of the OVV 4C29.45 over time scales ~20 min could be interpreted in terms of this idea. However, this model has to be worked out more carefully as the driving force behind those oscillations has not been analysed, nor is there any obvious reason to pick out a specific annulus of the disk that dominates the pulsations. A more sensible way of explaining short-period regular variations is to assume that the accretion disk contains one or various 'hotspots' which are spiralling into a black hole[12]. For a Schwarzschild hole, thin accretion disks have their innermost stable orbit at $6GM/c$, and thick disks reduce this value at $4GM/c$ (ref. 13). The radius of the event horizon of a Kerr black hole of mass M and angular momentum parameter a is (P. J. Wiita, preprint)

$$r=1.48\times10^5(1+\sqrt{1-a^2})(M/M_\odot)\ \text{cm} \qquad (1)$$

In the case of an extreme Kerr black hole ($a=1$), both the innermost bound and stable orbits coincide at $r=GM/c$. Thus a periodic phenomenon could exist down to timescales of

$$P=2\pi r/c\approx3.1\times10^{-5}(M/M_\odot) \qquad (2)$$

This expression yields a mass for the central black hole of $3\times10^7M/M_\odot$ for a 23-min period and $6\times10^7M/M_\odot$ for the 40-min one. These masses lead to Eddington luminosities of 5×10^{45} and 1×10^{46} erg s^{-1} respectively. These numbers are too small to explain the object's bolometric luminosity (we recall that at maximum light, $L_v\sim10^{47}$ erg s^{-1}). However, thick accretion disk models allow for actual luminosities that exceed L_E (ref. 14). Furthermore, one must still consider the effects of directed relativistic outflow (beaming)[15]. For a bulk relativistic Lorentz factor γ, the observed luminosity is enhanced by a factor of γ^2 and the total mass-energy required (for a fixed efficiency in the comoving frame) is reduced by a factor γ^4.

We conclude that the model that can explain our observations is one in which 'hotspots' in a thick accretion disk are spiralling down to a Kerr's supermassive black hole and are being periodically occulted by the disk itself. To have a beaming effect and to see the hotspots at the innermost part of the source, we must be viewing it almost pole-on (within $\sim11°$ of the rotation axis of the disk according to Sikora[16]) and the Thompson scattering depth τ_T, should be <1, which is likely to be the case for highly polarized objects (P. J. Wiita, preprint). The conflict between the real and observed luminosities can be resolved if an apparent luminosity of $\sim10\ L_E$ is produced by thick disk accretion coupled with bulk relativistic motions with $\gamma\sim2$.

The BL Lac-type object OJ287, with a redshift $z = 0.306$ and a luminosity exceeding 10^{47} erg s^{-1} at maximum light, is among the brightest and most violently variable objects of its class. Rapid variations, with timescales of a few hours or less, have been reported over a wide range of wavelengths[1,2] and also in polarization[3], imposing strong constraints on the size and dynamics of the source[4,5]. The detection of periodic variations in OJ287, or in any other compact extragalactic source, would be even more important, as these could be related to rotation or orbital motion in the source. So far the only searches sensitive to periodic variations shorter than 1 h are the photometric observations of Visvanathan and Elliot[6], Frohlich *et al.*[7] and Kiplinger[8], in which a 40-min period in OJ287 was respectively found, confirmed and not detected. We report here the detection of a 15.7-min periodic flux variation in OJ287 in April 1981 at 37 GHz. The source has been subsequently monitored for 265 h at 22 and 37 GHz, as well as in optical photometry, and the same period has been seen in simultaneous observations. The peak–peak amplitude of the variation is 1–10% of the total intensity. Other periods may also exist.

In the Turku-Otaniemi quasar variability monitoring programme[9], 20 quasar-type objects are observed for a period of, in the mean, one week each month with the 13.7-m radio telescope of the Helsinki University of Technology at Metsähovi, Finland. Each source is observed for a period of 1-2 h. During the measurement, a computer printout for every single integration segment (usually 50 s) is provided for control of the observation. On inspecting the printouts, we found that OJ287 was behaving differently from other sources and that an approximately 15-min periodicity was at times clearly visible even among the large noise of single integrations[10]. Subsequently, we observed OJ287 on several nights to ascertain whether periodic variations are really present.

The radio observations were made between April 1981 and May 1983. OJ287 was monitored for a total 265 h during 47 separate observing runs. We have used different observational procedures and integration times to check that the periodicities are not artefacts of our data-collecting methods or the spacing of observations. (Details of the observational procedures are presented elsewhere[9].) A typical run lasted about 6 h, with one data point (~50 s of integration time) produced every 2 min.

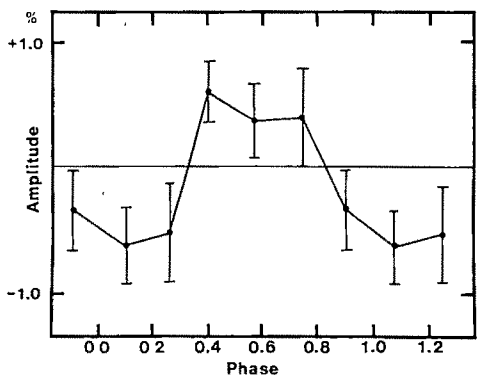

Fig. 3 The mean light curve of the 15.7-min variation from the NRAO observations. Error bars, $\pm 1\sigma$.

Thus, we had $n \sim 200$ points per run, with equal or unequal spacing (depending on the observing method) and some gaps attributable to calibration and optical depth measurements. The data for each run were then analysed by the Fourier technique of Deeming[11]. Because of the noise and data spacing, many peaks are apparent on the spectrum of a typical run. Among these peaks, one corresponding to a 15.7-min period is clearly visible on many nights and is shown in Fig. 1*a* for the run on 24 April 1981.

For a closer inspection of the observations, we have used the periodogram technique of Warner and Robinson[12], which is better suited for noisy data and non-sinusoidal variations. On nights where Fourier analysis indicates the presence of a clear 15.7-min variation, the periodogram technique helps to confirm the period, as well as giving the phase and the light curve of the variations.

On several occasions we were able to observe OJ287 on several consecutive nights. Although the long gaps between runs cause strong aliasing peaks, these can be identified by calculating the spectral window. If the 15.7-min variation is real, we would expect it to stand out more clearly in the combined data, whereas spurious peaks due to noise, unable to keep either phase or period from night to night, would be suppressed. Figure 1*b* shows the results of Fourier analysis for the combined runs of 5–7 March 1982 (595 observing points). Periodogram analysis gives a period of 943 s, in accordance with Fourier analysis. A comparison with similar data from combined runs, May 1981 onwards, indicates that the period may be constant to an accuracy of 1 s yr^{-1}.

To identify possible instrumental variations, we have made similar observations of a number of other sources and pure background noise, analysing these using the same techniques. Certain periodicities, for example, the peaks marked C in Fig. 1*b*, are caused by the radome and the variations in the electric current and are identified in most observing runs. Although no observing run is ever exactly repeatable and the periodicity could perhaps have been caused by some unknown mechanism, the most probable explanation is that the 15.7-min periodicity is intrinsic to OJ287, as we have not detected it in any of the other sources.

To ascertain whether the periodicity would be detectable with other instruments, simultaneous measurements were made on 26 February 1982 using the radio telescope at Metsähovi operating on 22 GHz, a double-beam chopping photometer using the 60-cm telescope of Metsähovi Observatory and using a similar photometer coupled to the 60-cm telescope at Turku Observatory, about 150 km west of Metsähovi. (The construction and operating principle of the photometers have been described by Piirola[13].) A standard observing procedure, with comparison stars measured at regular intervals, was followed. The measurements were made through the B filter. At the time of the observations, OJ287 was rather faint, with B (magnitude) = 14.6 mag, and the noise level of optical observations was rather high. The power spectra of all three runs were calculated and compared with each other and all three instruments showed a peak near the 15.7-min period: the radio telescope at 945 ± 15 s, the Metsähovi photometer at 980 ± 35 s and the Turku photometer at 935 ± 35 s, with the formal error limits derived from half-widths of the peaks.

To check for a coincidence, we further investigated all the peaks visible in each spectrum using the periodogram technique. In the case of the optical observations, the only periodicities found to have the same phase (within observational error) were those corresponding to the 15.7-min peak. In addition, the radio observations gave a similar light curve, but out-of-phase, and the amplitude of the variations seems to be the same at both wavelengths.

OJ287 was again observed with the 140-ft telescope of the National Radio Astronomy Observatory (NRAO) on 23 May 1983. The effective single integration times were 27 s and the total integration lasted 7.6 h, producing 330 observing points in all. Figure 2 shows the resulting power spectrum and Fig. 3 gives the mean light curve of the 15.7-min variation together with 2σ error bars. In addition to the 15.7-min power spectrum peak, strong peaks are visible at 33 min and 13 min. Both the 15.7-min peak and the 13.0-min peak were outstanding in the Metsähovi 37-GHz data (298 points over 6 h), also taken on 23 May 1983, but the 33-min peak was not observed.

Consequently, the 13-min periodic component, which has appeared on several occasions, has also attracted our attention. In addition, others[14] have observed a strong periodicity at 23 min between January and March 1983 in OJ287. Whether these periods are as durable as the 15.7-min period remains to be seen. Even in the case of the 15.7-min period, there are strong fluctuations in the amplitude, of $>15\%$ to $\sim 1\%$. An interesting parallel may be provided by the infrared observations of Wolstencroft *et al.*[2], where rapid, but presumably nonperiodic, variability was seen on only one night out of a total of 12, accompanied by a change in the shape of the infrared continuum. Simultaneous observations with different instruments are the only way to obtain definite proof for the existence of variations of this kind.

If only a single periodic component is confirmed, one may identify it with the rotation period of a single supermassive body[15–17]. However, if the evidence for many periodic components is sustained, then it is more probable that we are observing keplerian motion around a single dominant body with many different orbital radii, analogous to the modulation of the radio emission of Jupiter by its innermost moons. In any case, short periods such as 15.7 min indicate a relatively small mass for the central body ($\lesssim 10^7 M_\odot$) and a problem with the high luminosity of the quasar[4,5].

The work has been supported by a grant from the Academy of Finland. We thank the NRAO for the allocation of observing time for their 140-ft telescope and S. Haarala for help with the observations and data analysis. NRAO is operated by Associated Universities, Inc., under contract with the NSF.

Influences of precipitation changes and direct CO_2 effects on streamflow

T. M. L. Wigley & P. D. Jones

Climatic Research Unit, School of Environmental Sciences, University of East Anglia, Norwich NR4 7TJ, UK

Increasing atmospheric carbon dioxide concentrations are expected[1] to cause major changes in the world's climate over the next 50–100 yr. The impact of such changes on water resources, through changing precipitation and evaporation, will, however, be complicated by the direct effects of increasing CO_2 on vegetation. In controlled environment experiments, higher CO_2 levels cause the stomata of plants to close down, decreasing their rate of transpiration and increasing their water use efficiency[2]. Reduced evapotranspiration would make more water available as runoff and could

tend to offset the effects of any CO_2-induced reductions in precipitation or enhance the effects of precipitation increases. We consider here, in a simple but revealing analysis, the relative sensitivity of runoff to these two processes, changes in precipitation and changes in evapotranspiration. We show that, for low runoff ratios, small changes in precipitation may cause large changes in runoff. The magnitude and direction of these changes is, however, strongly dependent on the magnitude of the direct CO_2 effect on plant evapotranspiration.

Although much has been published on the climatic effects of increasing CO_2, few studies have considered the impact on water resources. Revelle and Waggoner[3] used empirical relationships to study the effect on water supplies in the western United States of a 10% reduction in precipitation and a 2 °C warming. They suggested that there could be large reductions in river flow. Rind and Lebedeff[4] used the results of a general circulation model (GCM) to examine possible runoff changes in the United States in a high-CO_2 world. Their results differed from those of Revelle and Waggoner, partly because of differences between the model-generated changes in climate and the scenario assumed in the earlier work, and partly because GCM-generated runoff data cannot be directly equated with measured riverflow (see ref. 5). Neither of these studies considered the direct effects of CO_2 on vegetation. Following Aston[6] (who used a distributed deterministic process model to simulate the effects of changed stomatal resistance on streamflow), Idso and Brazel[7] added the direct CO_2 effects associated with a CO_2 doubling to Revelle and Waggoner's analysis. The 40–70% reductions in streamflow in the absence of these direct effects became 40–60% increases when they were included. Such increases are of the same size as those predicted by Aston for catchments in eastern Australia. But how representative are these results?

If non-evaporative losses are small the mean annual water balance of a river catchment is given by

$$R = P - E \tag{1}$$

where R is runoff (here synonymous with streamflow), P is precipitation and E is evapotranspiration. The runoff ratio, γ_0, is defined by

$$R_0 = \gamma_0 P_0 \tag{2}$$

where subscript zero is used to denote present-day values. To estimate changes in runoff due to changes in precipitation and evapotranspiration we denote the change in precipitation (from P_0 to P_1) due to a doubling of atmospheric CO_2 by

$$P_1 = \alpha P_0 \tag{3}$$

Changes in evapotranspiration will occur for two reasons, as a result of climatic change and through direct CO_2-induced changes in vegetation. If we use β to denote the fractional change in evapotranspiration

$$E_1 = \beta E_0 = \beta_1 \beta_2 \beta_3 E_0 \tag{4}$$

then β can be considered conceptually as the product of three factors, β_1 the change due to a change of climate, β_2 the change due to a change in the area of vegetated cover (due to either climatic change and/or direct effects of CO_2 on plant growth), and β_3 the direct CO_2 effect on evapotranspiration. For a doubling of CO_2, β_3 is given approximately (and conservatively) by

$$\beta_3 \simeq 1 - 0.3a \tag{5}$$

where a is the fractional vegetated area of the drainage basin (see ref. 7). Manipulation of the above equations yields

$$\frac{R_1}{R_0} = \frac{\alpha - (1-\gamma_0)\beta}{\gamma_0} \tag{6}$$

This result can be used to assess the relative sensitivity of runoff changes to changes in precipitation (α) and/or changes in evapotranspiration (β). In particular, direct CO_2 effects can be studied using equation (5). The relative sensitivity is given by

$$\left| \frac{\partial(R_1/R_0)}{\partial\alpha} \Big/ \frac{\partial(R_1/R_0)}{\partial\beta} \right| = \frac{1}{1-\gamma_0}$$

Thus, runoff is always more sensitive to precipitation changes than to evapotranspiration changes, particularly for higher values of γ_0. Individual sensitivities, however, are higher for small γ_0. $\partial(R_1/R_0)/\partial\alpha$ always exceeds one, so that precipitation changes have an amplified effect on runoff, particularly in arid regions where γ_0 is small. This is a well-known result (see, for example, ref. 8). $|[\partial(R_1/R_0)]/\partial\beta|$ exceeds one for $\gamma_0 < 0.5$, so evapotranspiration changes only have an amplified effect for small γ_0.

Figure 1 shows the change in runoff for various changes in annual mean precipitation in the presence of a maximum direct

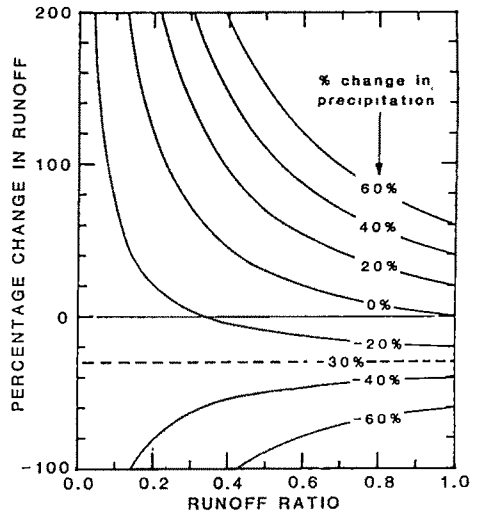

Fig. 1 Runoff changes due to changes in precipitation from a 60% reduction ($\alpha = 0.4$) to a 60% increase ($\alpha = 1.6$) assuming a maximum direct CO_2 effect on evapotranspiration ($a = 1$ in equation (5)) and no other changes in evapotranspiration ($\beta_1 = \beta_2 = 1$).

Table 1 Runoff ratios for some of the world's major rivers, listed approximately in order of mean annual discharge

River	Runoff ratio	River	Runoff ratio	River	Runoff ratio
Amazon	0.47	Parana	0.20	Niger	0.19
Congo	0.25	St Lawrence	0.33	Indus	0.40
Yangtze	0 50	Irrawaddy	0.60	Yukon	0.48
Brahmaputra	0.65	Ob	0.24	Nile	0.10
Ganges	0.42	Amur	0.32	São Francisco	0.15
Yenisey	0.42	McKenzie	0.40	Rhone	0.46
Mississippi	0.21	Columbia	0.51	Vistula	0.22
Orinoco	0.46	Zambezi	0 12	Volga	0.28
Lena	0.46	Danube	0.30	Murray	0.04

The values presented (based on ref 15) can only be taken as a general guide Data from different sources can vary widely because of difficulties in estimating natural flows and catchment area precipitation.

CO_2 effect ($a = 1$). For smaller runoff ratios (that is, more arid regions) any given change in precipitation has an increasingly large effect on runoff. When $\alpha = 0.7$ and $a = 1$, equation (6) reduces to $R_1 = 0.7\,R_0$, so that the runoff change is independent of the runoff ratio. For $0.7 < \alpha < 1.0$, runoff may increase or decrease depending on the value of γ_0. For $\alpha > 1.0$ runoff always increases (as the precipitation and evapotranspiration changes act in the same direction). The magnitude of the increase can be very large for small runoff ratios.

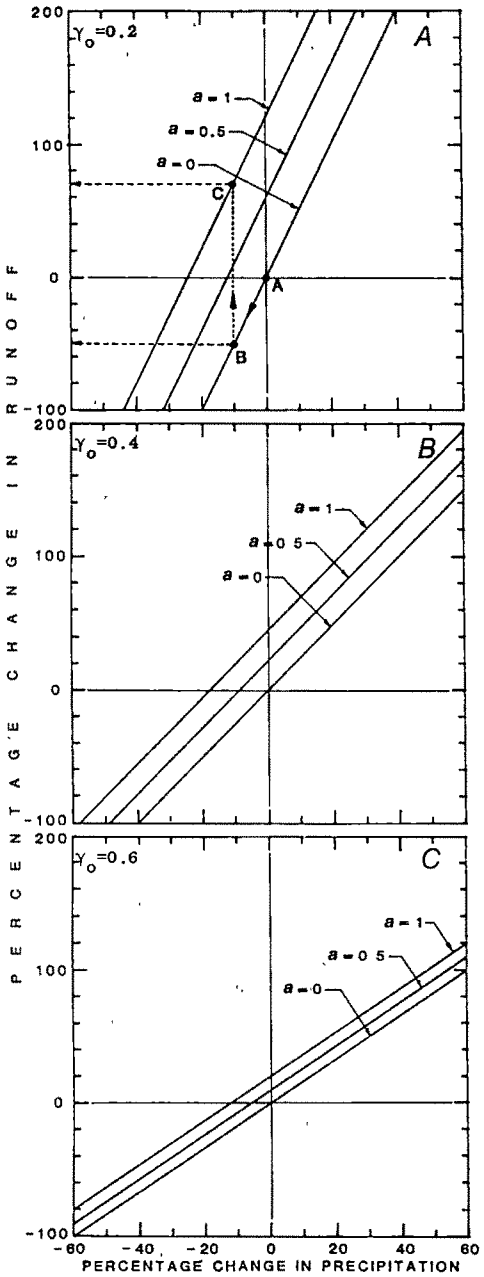

Fig. 2 Runoff changes due to precipitation changes for different evapotranspiration changes. $a = 0$ corresponds to no change in evapotranspiration, whereas $a = 1$ corresponds to a 30% reduction in evapotranspiration (the maximum direct CO_2 effect). The sensitivity to both precipitation change and evapotranspiration change increases for decreasing runoff ratio, γ_0. Three values of γ_0 are shown (*A*, $\gamma_0 = 0.2$; *B*, $\gamma_0 = 0.4$, *C*, $\gamma_0 = 0.6$) spanning the most common range of observed values *A* ($\gamma_0 = 0.2$) includes a specific illustration. The effects of precipitation change alone are determined by the $a = 0$ lines. The line AB, therefore, shows the effect of a 10% reduction in precipitation. The effects of evapotranspiration change are determined by paths parallel to the ordinate. Thus, BC corresponds to a range of evapotranspiration reduction from 0% (point B) to 30% (point C). Point C (and the lines $a = 1$ in general) corresponds to the maximum direct CO_2 effect, but the precise cause of the evapotranspiration change is unimportant.

Table 1 lists runoff ratios for some major rivers. Values range from 0.1 or less for rivers which flow through arid regions up to more than 0.6 for some tropical rivers. In temperate latitudes, runoff ratios around 0.4 are fairly typical. Equation (6) may not be directly applicable to rivers with the lowest runoff ratios in Table 1. Some of these obtain most of their water from relatively small, high precipitation headwater catchments and then flow through arid and largely unvegetated regions. The runoff ratios given in Table 1 are for the whole drainage basin and may, in these cases, fail to represent conditions in the hydrologically-active parts of the basin.

Figure 2 shows the sensitivity of the runoff-change–precipitation-change relationship to the direct effects of CO_2 for various values of the runoff ratio. The magnitude of the direct effect can be varied by changing the parameter a. When $a = 0$ the direct effect is zero, and when $a = 1$ the direct effect is a maximum. The effects of climate related changes in evapotranspiration can also be studied using Fig. 2 since the range $a = 0$ to 1 corresponds to a range of β values from 1.0 to 0.7, that is to a range of reductions in evapotranspiration from 0 to 30%. The slopes of the lines in Fig. 2 are greatest for smallest γ_0, showing that precipitation changes have maximum effect for small γ_0. Thus, for small γ_0 (as noted earlier), precipitation changes may show a considerably amplified effect in runoff.

As an example, for a catchment with present runoff ratio of 0.2, the effect of a 10% reduction in precipitation may range from a 50% reduction in runoff with no direct CO_2 effect, to a 70% increase in runoff with a maximum direct CO_2 effect. For higher runoff ratios the range of possible runoff changes is less (see Fig. 2). In both Aston's[6] study and the Idso and Brazel[7] study, runoff ratios were low, around 0.16 in the latter case. This low value explains why Idso and Brazel obtained such vastly different results from Revelle and Waggoner[3] when they incorporated the direct effects of CO_2. Table 1 shows that such low runoff ratios are unusual. Nevertheless, the direct CO_2 effect can still be substantial for more common runoff ratios. Idso and Brazel's case may also be unrepresentative of global conditions because they assumed precipitation reductions due to increasing CO_2 (following Revelle and Waggoner[3]). Climate model results all point to an increase in the intensity of the hydrological cycle and an overall (albeit slight) increase in global mean precipitation. There will, of course, be regionally and seasonally specific exceptions to this overall trend, but, in general, the effects of precipitation change and vegetation changes can be expected to reinforce each other. In some regions, therefore, we might expect very large increases in annual mean runoff, unless these are compensated by large climate-related increases in evapotranspiration.

The extent of this compensation is difficult to estimate because the magnitudes of climate-related changes in evapotranspiration due to increasing CO_2 are unknown. Over the land, evapotranspiration changes will result from several competing factors: warmer temperatures, changes in the length of the growing (evaporative) season, changes in wind speed, changes in cloudiness, and so on. Some of these factors may cause either increases or decreases in evapotranspiration. Although existing GCMs have recognized deficiencies in the way they model the hydrological cycle[9], they still provide the best available guide to the climatic effects of increasing CO_2. All GCMs show an increase in the intensity of the global hydrological cycle. The increases vary considerably from model to model and are larger for models which show greater global-mean warming. For a doubling of CO_2 the global-mean increases in precipitation and evaporation range between about 3% (ref. 10) and 11% (ref. 4). These increases in evaporation are much less than the maximum direct CO_2 transpiration effect. However, there may be appreciable regional and/or seasonal departures from the global mean (see ref. 4) so, at least in some regions, we might expect the climate effects to modify the direct effects significantly.

The above analysis ignores several important factors. For example, the seasonal distribution of precipitation may be very different from that of evapotranspiration, and direct CO_2 effects may be diminished if the major contribution to runoff is in the winter months[11]. Seasonal effects are, however, complex. For example, if E is defined as the residual of $P-R$ (equation (1)), then our results are independent of the seasonal distribution of precipitation. Direct CO_2 effects may also be reduced if increasing CO_2 causes an increase in leaf temperatures, in individual plant leaf areas or in the total vegetated area of a catchment[11,12]. More complex catchment models (such as the statistical models of Wright[13] and Jones[14], or deterministic models like that used by Aston[6]) are required to study these effects. Our study does, however, provide a basis for first estimates of annual mean runoff changes for any river whose runoff ratio is known, and allows one to identify regions most likely to experience large runoff changes due to increasing CO_2.

Carbon dioxide research in the Climatic Research Unit is supported by the US Department of Energy under grants DE-AC02-79EV10098 and DE-AC02-81EV10738. We thank T. C. Atkinson for useful comments.

Gypsum precipitation from cold brines in an anoxic basin in the eastern Mediterranean

Scientific staff of Cruise *Bannock* 1984-12*

In 1968 hot brines from which gypsum had precipitated were discovered in the Red Sea, in a divergent plate boundary setting with hydrothermal activity[1]. We now report the discovery of cold brines in an entirely different geodynamic situation, a convergent plate boundary in the eastern Mediterranean, where the heatflow is very low[2] and no hydrothermal activity occurs. Decimetric pure gypsum crystals precipitate from the cold brines, which occupy the bottom of a rimmed anoxic basin near the southern edge of the Mediterranean Ridge, close to the Sirte Abyssal Plain. Nucleation of the crystals does not occur at the surface, but from the deep brines, because the salinity of the water is normal down to the depth of −3,000 m. We propose the name 'Bacino Bannock' for this basin, after the Consiglio Nazionale delle Ricerche R/V *Bannock* from which the bottom-water brines were surveyed and sampled.

* The following participated in the *Bannock* cruise M B. Cita†, K A Kastens‡, F W McCoy‡, F Aghib†, A Cambi§, A Camerlenghi†, C Corselli†, E Erba†, M Giambastiani†, T Herbert‖, C Leoni†, P Malinverno†, A Nosetto† & E Parisi†
† Department of Earth Sciences, University of Milano, Milano, Italy ‡ Lamont-Doherty Geological Observatory of Columbia University, Palisades, New York, USA § Department of Earth Sciences, University of Firenze, Firenze, Italy ‖ Department of Geology, Princeton University, Princeton, New Jersey, USA

Another anoxic basin containing highly saline bottom water was discovered last year in the western Strabo Trench, north o the Mediterranean Ridge, and named Tyro Basin[3]. Bacin Bannock differs from Tyro in that gypsum precipitation is onl recorded in the former.

Bacino Bannock was discovered using Seabeam and Seamar I during the *Robert D. Conrad* Cruise 25-06 (April 1984). I September 1984, *Bannock* Cruise 84-12 completed a narrow beam echosounder bathymetric survey of the basin, obtaine 10 cores and two dredges, and conducted three CTD (conduc tivity/temperature/depth) stations and one Nansen-bottl hydrocast. Navigation on both *Conrad* and *Bannock* was b Loran-C and transit satellites.

Bacino Bannock is an irregular depression (Fig. 1) about nautical miles (15 km) in diameter, within the irregular 'cobble stone topography' of the Mediterranean Ridge. A prominen bulge occupies the centre of the basin, surrounded by a moat-lik depression. The Bannock sampling programme was concen trated on, and to the west of, the central bulge, where th depression is deepest.

Sediment cores (Fig. 2) from 3,000 m and shallower contai the typical eastern Mediterranean pelagic stratigraphy o sapropels and tephras. However, bottom sediments collecte deeper than 3,200 m are black to dark grey and smell strongl of hydrogen sulphide. This anoxic environment contains stratigraphy of tephra layers, breccias, carbonate sands an graded sands and silts. All samples examined at sea were richl fossiliferous, with varying proportions of planktonic and dis placed benthic foraminifera (*Asterigerinata mamilla, A. planor bis, Asterigerina* sp., *Gavelinopsis lobatulus, Rosalina globularis* etc.), calcareous nannoplankton and siliceous plankton. Anoxi sediments are over 9 m (implying a sedimentation rate o 10 cm kyr^{-1} in our longest core) and range in age from Holocene probably to middle Pleistocene, as based on a combination o calcareous nannofossil biostratigraphy (*Gephyrocapsa oceanic* Zone) and planktonic foraminiferal palaeoecology.

A basal normal contact between anoxic and pre-anoxic sedi ments was not recovered. However, two cores (below 3,150 m 05 and 06 GC) recovered oxic pelagic sediments of middle an late Pliocene age unconformably beneath Holocene anoxic sedi ments and in a breccia, respectively.

Abundant gypsum in cores and dredge hauls was the mos surprising discovery at Bacino Bannock. In cores, individua crystals range in size from microscopic to the full diameter o the core barrel (7 cm). The dredges recovered enormous masse of interlocked gypsum crystals, up to 0.5 m across (Fig. 3). Botl dredges were caught up in the gypsum and required more tha 5 tons of pull and several hours (more than 24 h at station 11 D to be freed. These composite gypsum masses were only recovere from the steep western wall of the central bulge where the adhered to a hard substrate of grey Pleistocene marlstone individual crystals in cores and dredges were both tabular an bipyramidal and many contained inclusions concentrated alon crystal planes. Inclusions consisted of pelagic debris such a planktonic foraminifera (Fig. 4), including *Globigerina bulloide Globigerinoides ruber* and *Orbulina universa*, pteropods, includ ing the Holocene species *Cavolinia gibbosa*, and *Cavolini inflexa, Clio pyramidata* and *Atlanta* sp., and mineral grains.

Rubbery mats, similar to those described from the Tyro Basin and consisting of organic fibres containing diatoms, planktoni foraminifera and mineral grains, were found in both cores an dredges. In cores, the mats were recovered as horizontal disk presumably cut from larger mats as though by a biscuit cutte in dredges they occurred between crystals, with no preferre orientation.

CTD measurements indicate normal Mediterranean deep water down to 3,000 m (the length of the conducting hydro-cabl on board). A 15-kHz echosounder recorded horizontal reflector within the water column at depth of 3,228, 3,428 and 3,325 m suggesting locally-high gradients in temperature, salinity and/o particulate matter. During coring and hydrocast operations, th depth of the instrument was monitored by an acoustic pinge

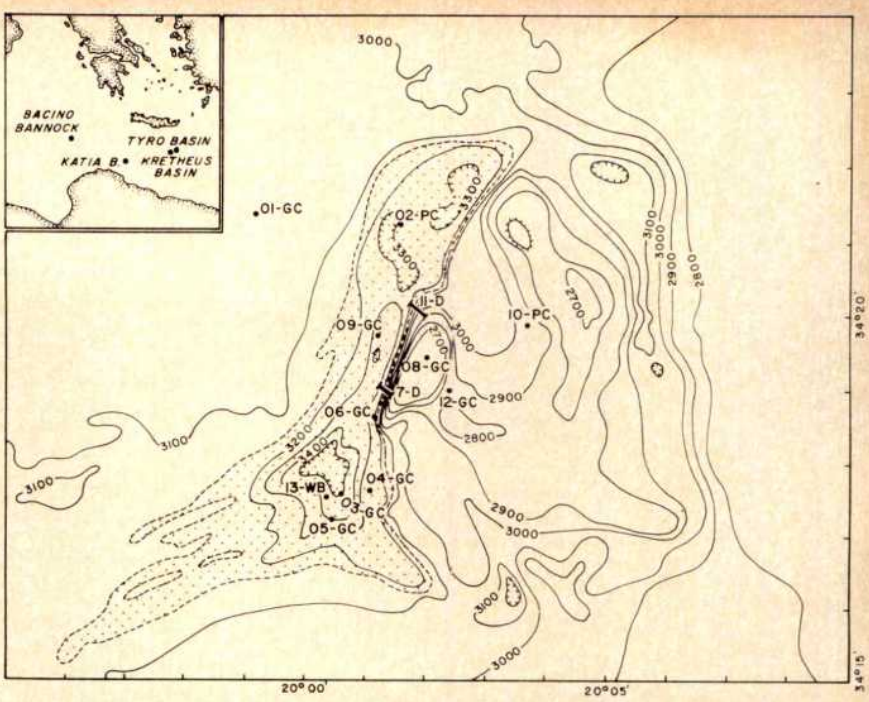

Fig. 1 Bathymetry of Bacino Bannock as determined by 3.5-kHz narrow-beam echo sounder and Seabeam. Contour interval is 100 uncorrected metres. Sampling stations are: D, dredge; GC, gravity core; PC, piston core; WB, water bottle cast. The brine (light stipple pattern) is confined beneath the 3,150-m contour. Navigation is by Loran-C, adjusted to satellite coordinates. Note location of Tyro and Kretheus Basins, where anoxic bottom conditions were discovered last year[3] and of Katia Basin, where such conditions were found during the present investigation.

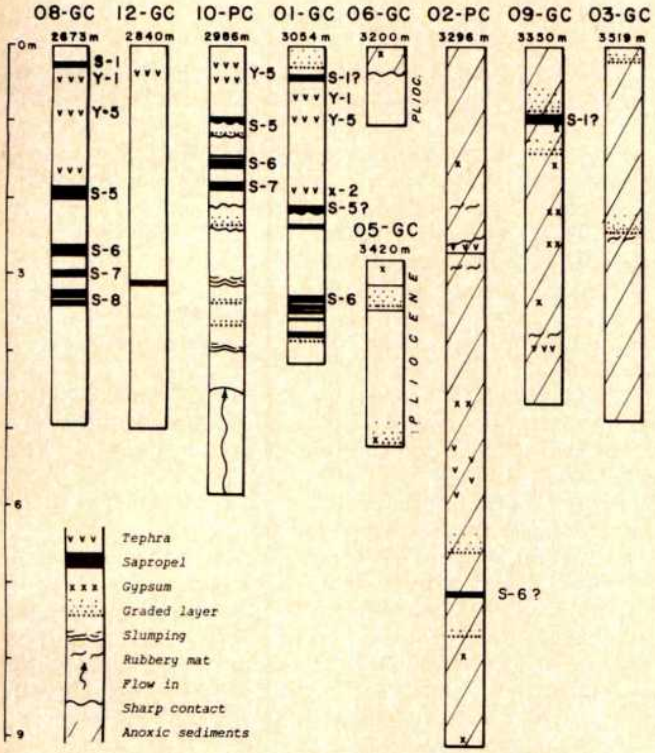

Fig. 2 Simplified core logs from Bacino Bannock. Cores shallower than 3,000 m were recovered from a normal eastern Mediterranean pelagic sequence including sapropels and tephras, whereas cores deeper than 3,200 m were recovered from grey and black sediments.

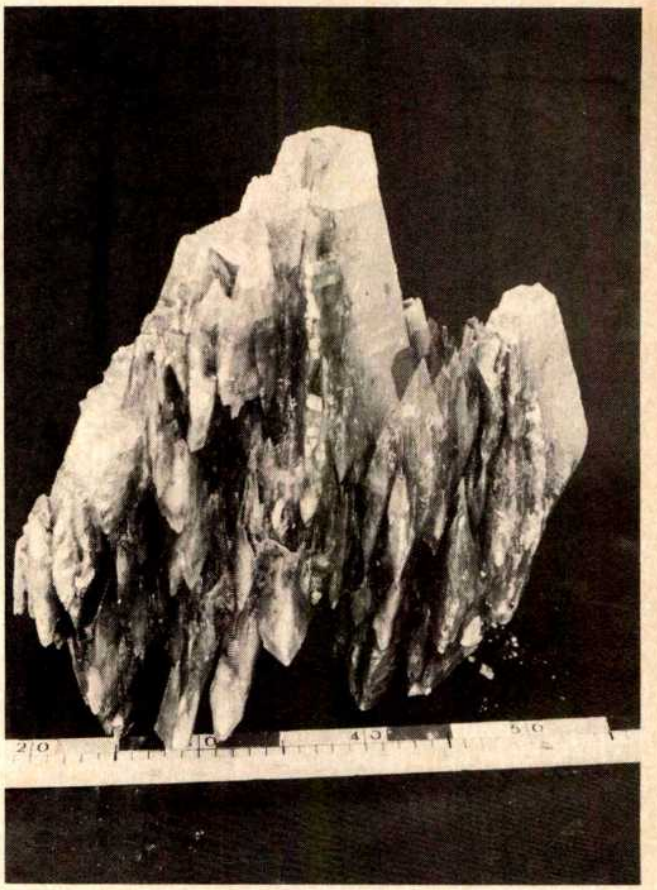

Fig. 3 Photograph showing a large mass of interlocked gypsum euhedra recovered in dredge 7-D (scale in cm). The size and perfection of the euhedra suggest that this gypsum was recently crystallized from a hypersaline brine rather than being relict from the Messinian.

displayed on a facsimile recorder as a depth versus time plot. As the pinger neared the bottom of the basin, a break in the slope appeared on the plot, which we believe resulted from an abrupt change in sound velocity occurring somewhere between 3,100 and 3,340 m.

We infer from sound velocity contrast measurements that the black muds, stinking of hydrogen sulphide, are best explained by the presence of anoxic hypersaline bottom water as has been recovered from the Tyro Basin[3,4]. The upper level of the hypersaline brine is inferred to be at the level of the shallowest closed contour, 3,150 m. This is in agreement with echosounder mid-water reflectors, sound velocity contrast and water depths from which anoxic and oxygenated sediments were recovered. The estimated depth of the interface is consistent with CTD observations that showed no increase in salinity down to 3,000 m. The bottom-water layer occupies an area of 36 km^2 and has a volume of ~4 km^3.

The most probable source of hypersaline bottom water is by leaching from latest Miocene (Messinian, approximately 6–5 Myr BP) evaporites. Although we did not sample strata of this

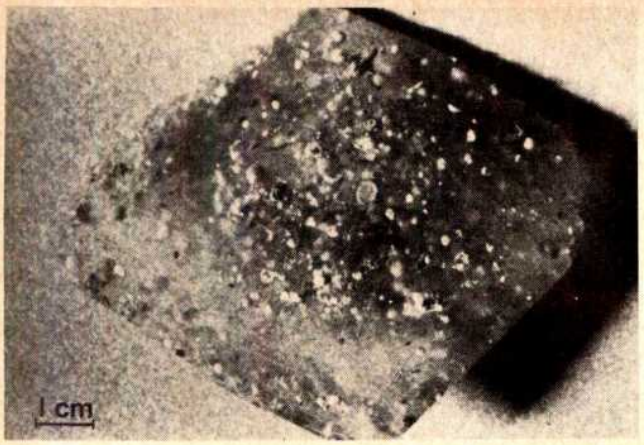

Fig. 4 Photograph showing a euhedral gypsum crystal recovered in core 09 GC, Sec. 1, 80 cm from core top. The numerous biogenic inclusions consist of planktonic foraminifera.

age, several pieces of evidence suggest that Messinian sediments must be at, or close to, the sea floor. First, a single channel reflection profile 10 km west of Bacino Bannock shows a regional reflector (layer M) that correlates with the top of Messinian evaporites[5,6] at sub-bottom depth of 100 m. Second, sedimentation rates calculated for the plateau cores (01, 08 and 10) range from 1.5 to 2 cm kyr^{-1}. Extrapolating this sedimentation rate to 5 Myr BP gives a maximum thickness of 100 m for the Plio-Quaternary section.

At present, gypsum appears to be precipitating from the hypersaline brine at the seafloor. This is indicated by the size and perfection of the crystals, as well as the age of their substrates and inclusions. Gyspum found down-core could have precipitated either from bottom water, before burial at the sediment-water interface, or from pore water, after burial within the sediment.

The degree of anoxia and/or hypersalinity may have varied with time as shown by the change in colour intensity down-core, and by the irregular distribution of gypsum crystals. Some of the sediments are indeed re-sediments, as suggested by the occurrence of millimetric silty laminae, high sedimentation rate and the presence of benthic foraminifera, mostly displaced down-slope. It is possible that the variations in the degree of anoxia were responses to eastern mediterranean-wide hydrographic conditions, as well as to local phenomena. A jet-black layer at 711 cm in core 02 PC, which may correlate with sapropel S-6, contains a cold-water fauna dominated by *G. bulloides* and *Globoquadrina dutertrei*. This fauna characterizes the middle Pleistocene 'glacial anoxia' event observed throughout the eastern Mediterranean[7]. The base of this core is referable to the middle Pleistocene *G. oceanica* nannofossil zone.

The Mediterranean Ridge is marked by numerous subcircular depressions, some of which have been interpreted as resulting from dissolution and collapse of Messinian evaporites[8,9]. Thus, it is reasonable to expect strong density stratification and consequently, anoxic bottom waters in other basins. Indeed, Jongsma *et al.*[13] have described anoxic conditions present now in the Tyro Basin, and up to a few thousands years ago in the adjacent Kretheus Basin, both in the Strabo Trench. On *Bannock* cruise 84-12, we also identified anoxic conditions (cores 29 PC and 30 GC) that lasted until a few thousand years ago in basins of the Katia area near the Lybian continental margin.

In conclusion, we note that the unique aspect of Bacino Bannock is the deep water precipitation of the gypsum under very specific geological, chemical, hydrographical and physiographical conditions.

We thank the officers and crew of the R/V *Bannock* for their assistance and especially Comandante A. Mancuso and First Officer A. Patane for their contribution to the success of the cruise. Abundance variation of iridium and trace elements at the Permian/Triassic boundary at Shangsi in China

Xu Dao-Yi*, Ma Shu-Lan†, Chai Zhi-Fang†, Mao Xuo-Ying†, Sun Yi-Ying‡, Zhang Qin-Wen§ & Yang Zheng-Zhong‖

Despite recent searches for anomalous iridium(Ir) concentrations at the Permian/Triassic boundary (P/Tr) of marine sediments[1-3], no Ir above a level of 0.5 p.p.b. (parts per 10^9) has been found. Detailed event–stratigraphical research has revealed a comparatively high platinum-group enrichment and geochemical anomalies of trace elements in the P/Tr boundary clay at Meishan, Changxing County, Zhejiang Province, China[4]. We report here an investigation of Ir and trace-element abundances in the P/Tr boundary layer of Shangsi section, Guangyuan County, Sichuan Province (Fig. 1). An Ir value of 2 p.p.b. detected in the boundary layer supports the occurrence of an extraterrestrial event at the end of the Permian.

The Shangsi P/Tr layer is located in a road section ~1 km from the town of Shangsi. This section has been extensively investigated, so that stratigraphical sequences of the Permian and Triassic are clear. However, opinions differ as to the demarcation of the P/Tr boundary; most hold that the boundary is close to the horizon where sample AG253 was collected[5].

We concentrated on the P/Tr boundary sediments of total thickness 4 m and most of the samples were collected from shales and clay. The stratigraphical sequence of measured section is shown in Fig. 2.

Note that in South China, *Pleuronodoceras* sp., *Pseudotirolites asiaticus* and *Neogondolella changxingensis* in layer 3-5 are index fossils usually present at the top of the Changxingian. However, a new species of *Claraia* was also found. Hence, the different fauna groups provide several options on where to put the P/Tr boundary in the Shangsi section. For instance, the base of the Triassic has been placed between layer 2 and 3, according

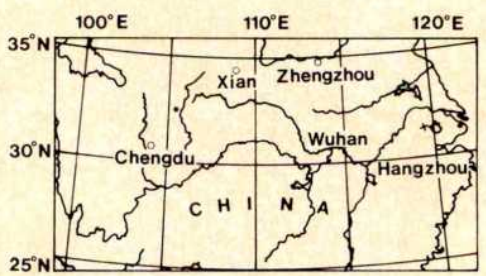

Fig. 1 Sketch map of the locations of two Permian/Triassic sections. *, Shangsi section, Guangyuan; ×, Meishan section, Changxing.

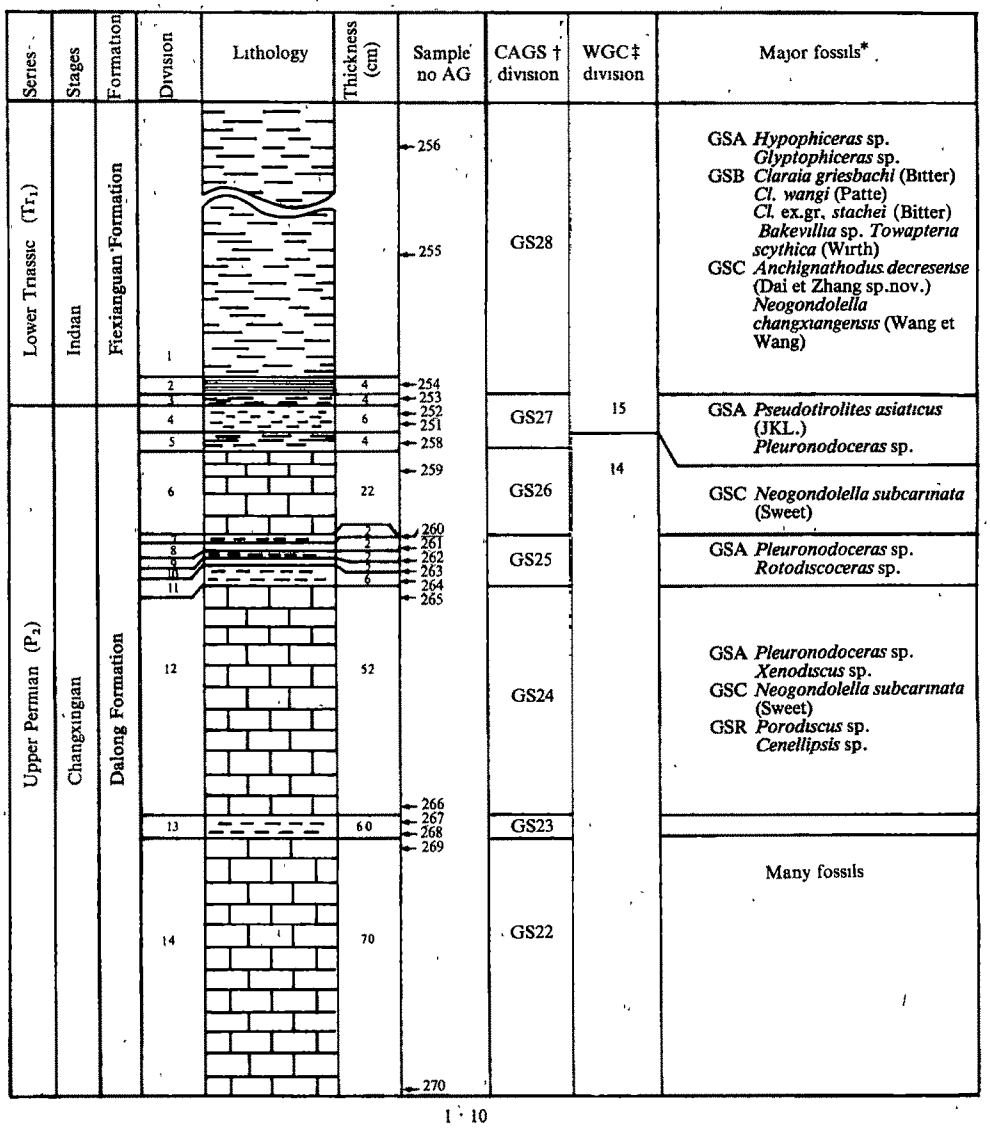

Fig. 2 P/Tr boundary stratigraphical section at Shangsi, Guangyuan. *, From Li Zishun; †, Chinese Academy of Geological Science; ‡, Wuhan College of Geology. Divisions: 1, silty shale; 2, grey shale; 3, grey-black calcareous shale; 4, light coloured shale; 5, grey-black calcareous shale; 6, grey siliceous limestone; 7, grey shale; 8, dark-grey calcareous shale; 9, grey shale; 10, dark-grey siliceous shale; 11, grey shale; 12, dark grey siliceous limestone; 13, grey shale; 14, dark-grey siliceous limestone.

to the ammonites. But, from the bivalves, the P/Tr boundary is lower, whereas conodont assemblage favours moving the P/Tr boundary much higher.

We analysed 10 samples from Shangsi P/Tr section by instrument neutron activation analysis (INAA); the analytical results are shown in Table 1. To check the reliability of INAA, some samples of Cretaceous/Tertiary boundary clay from several sections in Western Europe were also measured. The results seem to concur.

From the 10 analysed samples, only one (AG253) shows an Ir concentration of 2.0 ± 0.5 p.p.b., which is based on two laboratory runs, the lower limit of detectable Ir in the analyses is about 0.5–0.6 p.p.b. Note, that the Shangsi samples, investigated by Zhang *et al.*[3], were taken from layers GS25 and GS24 (equivalent to layers 11 and 12 in the present study), which lies ~0.5 m lower than sample AG253.

Table 1 shows the data sets of the abundance variation of 14 other elements. There are two variation trends: elements of the

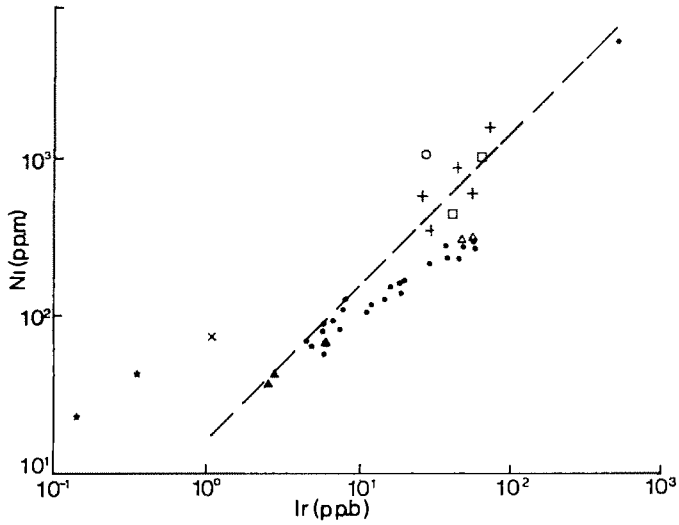

Fig. 3 Relationship between Ni and Ir content in the boundary rocks of the Permian/Triassic (P/Tr); Cretaceous/Tertiary (K/T) X, Crust; *, CI; †, Tunguska metallic spheres[6]; ▲, P/Tr boundary beds at Shangsi; ★, average Danish K2 E1 rocks (from ref. 8); ●, average Danish K/T boundary bed (from ref. 9); ⊙, average Danish K/T boundary bed (from ref. 8); □, average Danish K/T boundary bed (from ref. 7); △, average Danish K/T boundary bed (from ref. 10).

first trend reach maximum or sub-maximum values at AG253. This is the situation for siderophile elements (Ni, Cr, Fe), chalcophile (meteorite) elements (Sb) and a few lithophile elements (Ba, Rb). Most of the lithophile elements (Cs, Rb, Hf, Ta, Zr, Th, U and so on) belong to the second variation trend, which shows decreasing elemental concentrations in sediments of younger geological ages. So, there is probably little or no correlation between the Ir anomaly and the variation trend of most lithophile elements. However, the variation of Fe, Ni, Cr and so on shows a close correlation to the Ir anomaly in sample AG253.

Ganapathy[6] has used the Ni/Ir ratio to distinguish metallic microspherules of an extraterrestrial origin from those of terrestrial origin: on an Ni–Ir diagram, microspherules of extraterrestrial origin show regular linear distribution. Figure 3 shows the Ni and Ir contents of CI carbonaceous chondrites, Tunguska microspherules and Danish Cretaceous/Tertiary boundary clay. These points tend to an approximately linear distribution. The slope of the dashed line in Fig. 3 reflects the cosmic ratio of Ni and Ir. The Ni/Ir points of Shangsi and Meishan samples plotted on Fig. 3 fall into a linear distribution area. Figure 3 also shows that the Ni and Ir values of the crust, Upper Cretaceous beds and Lower Palaeocene beds from Denmark deviate from the linear distribution.

The evidence from the mass extinction of biocommunities, the Ir anomaly of AG253, the variation in the abundance of trace elements, and the comparison between the platinum anomalies at P/Tr boundary at Meishan, Changxing[4] and those at the end of Cretaceous throughout the world, supports the conclusion that the 2 p.p.b. Ir anomaly in AG253 reflects the effects of an extraterrestrial event that occurred at the end of Permian.

Study of the Ir anomaly may provide a new approach to stratigraphical subdivision and correlation. The above arguments place the P/Tr boundary at the Shangsi section at the base of layer 3.

This paper is only a preliminary report and more detailed studies are being planned.

We thank Professor Yang Zun-Yi for field assistance, Yang Ji-Duan, Li Zishun, Jin Ruogu (Chinese Academy of Geological Science) and Yin Hongfu (Wuhan College of Geology) for help during our joint field work in 1983. The fauna list used in this paper was provided by Dr Li Zishun. This work was supported by the Scientific Foundation, Academia Sinica.

Timing of deglaciation from an oxygen isotope curve for Atlantic deep-sea sediments

W. H. Berger, J. S. Killingley & E. Vincent

Scripps Institution of Oceanography, University of California, San Diego, La Jolla, California 92093, USA

The exact timing of deglaciation is an important issue in the context of climatic feedback involving the deglacial rise in atmospheric CO_2 seen in ice cores[1–4]. We have produced evidence, from box cores taken in the equatorial Atlantic, that the last deglaciation occurred in two major steps which were separated by a brief pause[5]. Here we propose that this pause is equivalent to the period of glacial readvance known as 'Younger Dryas', which lasted from about 11 to 10 kyr BP. If our correlation is correct, then the initiation of deglaciation occurred after 14 kyr BP, which disagrees with most other deep-sea timescales.

Two-step deglaciation has been proposed previously, notably by Duplessy *et al.*[6] who based their conclusions both on extensive micropalaeontological work at the Institut de Géologie du Bassin d'Aquitaine, and on new radiocarbon-dated $\delta^{18}O$ signals measured at Gif-sur-Yvette. Berger[7] proposed that the Atlantic deep-sea deglaciation record is correlated, as a two-pulse feature, with the record in the Gulf of Mexico[8] which clearly shows a double-pulse meltwater input[9]. Independently, Ruddiman and McIntyre[10] came to the conclusion that deglaciation occurred in major pulses, based on the micropalaeontological record in North Atlantic sediments.

The pulsed nature of the last deglaciation, then, appears to be well established. However, strong disagreement persists concerning the matter of timing[11,12]. Several papers[8–10] date the beginning of deglaciation well before 15 kyr BP. In contrast, our data from the Pacific suggested that deglaciation commenced after this time[13]. Also, the data given for the Gulf of Mexico by Emiliani *et al.*[14] show no major influx there before 14 kyr BP. The timescale of Duplessy *et al.*[6] has deglaciation beginning near 15,000 BP. Sarnthein *et al.*[15] suggest that "the Termination I continued from about 16,000 to 8,500 yr BP", but consider that tropical planktonic foraminifera "indicate a delayed ocean warming which did not start till 14 kyr BP", in the Northern Hemisphere.

The chief problem with accepting any of the published timescales is the varying quality of radiocarbon ages in deep-sea sediments; despite special precautions, problems persist. The well-dated core of Duplessy *et al.*[6] (Core CH 73139C, west of Ireland), for example, shows virtually identical radiocarbon ages for the section between 110 cm and 145 cm, namely, 11.5–11.7 kyr, as well as a major break in sedimentation rate near 200 cm. These results suggest that the record suffers from redeposition events and/or other disturbances. Although the ages down to Ash Layer 1 appear correct (the date of this layer is near 10 kyr), the older ages downcore are suspect. Within the crucial interval centred on 15 kyr, little or no planktonic carbonate may have been delivered to this site because of its northern position[10].

Our box-core data (Fig. 1) allow an independent assessment of the reliability of bulk carbonate ages. For this purpose, the cores are correlated on the basis of oxygen isotopes, with support

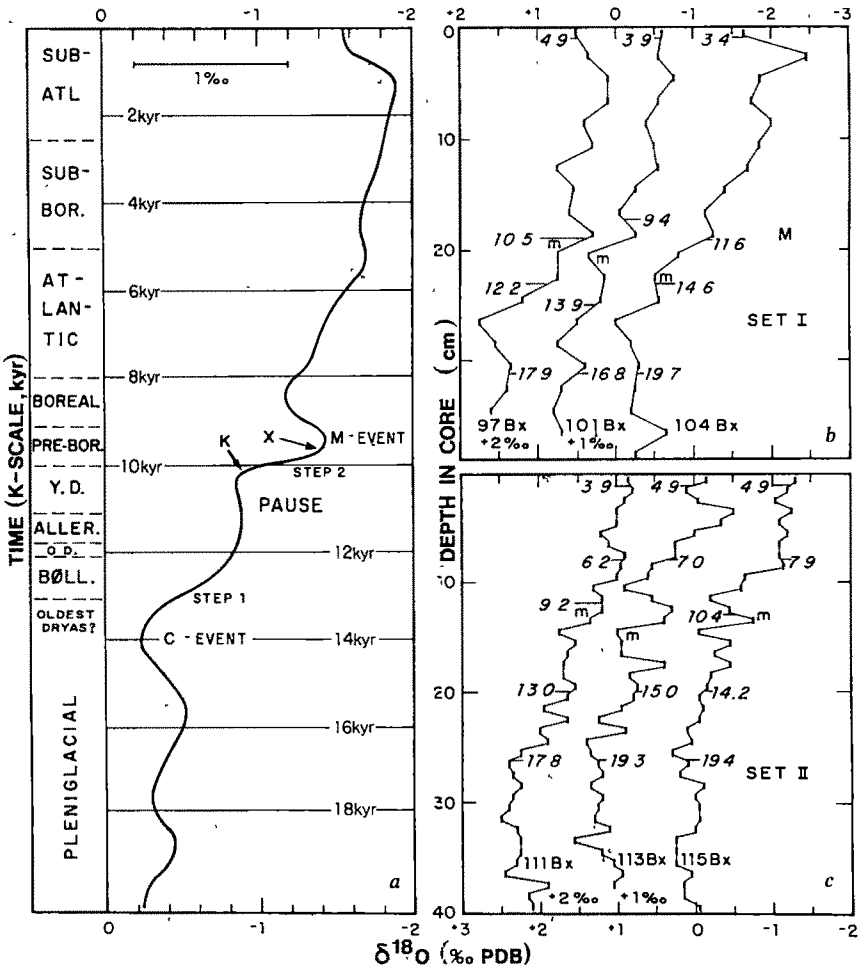

Fig. 1 Timescale of deglaciation based on stacked $\delta^{18}O$ record of three equatorial cores from the Atlantic (*a*). K, the fixed point, taken as end of Younger Dryas, at 10.2 kyr X, The level where radiocarbon ages of bulk carbonate are 11 kyr on average. The K-timescale is based on position of point K and linear sedimentation rate. *b*, $\delta^{18}O$ records from three box cores from the equatorial Atlantic, and ^{14}C dates in kyr. m, Appearance of *G. menardii*. M-event, a 'warm' excursion in the $\delta^{18}O$ record at the end of deglaciation thought to be correlative with the Gulf of Mexico meltwater event of refs 8, 9, 14. *c*, Similar to *b* but cores from tropical South Atlantic. $\delta^{18}O$ measures against PDB standard (*G. ruber*, pink).

from the appearance of the planktonic foraminifera *Globorotalia menardii*, a Holocene marker species. The data plotted in Fig. 1*b,c*, demonstrate that there are two sets of cores whose sedimentation rates are almost identical. Within each of these sets, correlation coefficients are very high (≥ 0.9). They are diminished when differences in overall sedimentation rates are assumed, as we established by systematic numerical experiments. Depth levels within these sets, then, are more or less synchronous. The synchroneity, presumably, tends to deteriorate with depth-in-core, as small differences in sedimentation rates lead to increased divergence in age. If we accept synchroneity within sets for Holocene sediment (<11 kyr), a typical standard deviation about the mean of radiocarbon ages is 0.5–0.9 kyr (Table 1, second and fourth column). This uncertainty seems to reflect the confidence which can be put in the dating of isotope signals based on bulk radiocarbon in these cores. The scatter is a result of sampling and counting errors, mixing processes, and redeposition of fine-grained carbonate. These radiocarbon age data, quite clearly, cannot be used for arguments involving time-resolution of <1,000 yr.

In the following analysis, we use the radiocarbon dates for general guidance: the detailed timescale we propose is based on the correlation of climatic signals. We argue that the radiocarbon dates must be considered maximum ages. Our chief evidence is the high average age of surface sediments (4.1 and 4.6 kyr, Table 1). High surface ages have been reported previously from deep-sea carbonates, they were explained by benthic mixing processes[16,17]. To a first approximation the age of the mixed layer represents the residence time of particles in the mixed layer reservoir, whose thickness should be close to $s \times t$, where s is the sedimentation rate and t the age. For our cores ($s = 1.5$ to 2 cm kyr^{-1}) this thickness would be between 7 and 8 cm. Such a high value conflicts with expectations for these areas[18], especially for the set II region where ocean productivity is low and benthic stirring therefore reduced[19]. We suggest that the old surface ages result not from vertical benthic mixing so much as from the lateral advection of old fine-grained carbonate, delivered from elevated areas. Direct evidence for 'old' fines is in the comparison of coarse fraction ages with bulk ages (Table 2). The bulk ages are older by about 2 kyr, on average. The fines, then, must be older than the coarse material by 2.5 to 3 kyr. Discrepancies in the ages of coarse and fine fractions of deep-sea carbonates have been reported previously[20,21]. The point is that the climatic signals, carried in the isotope composition of planktonic foraminifera, is embedded within sediment that is too old, as far as the signal's timescale is concerned.

Table 1 Average ^{14}C ages (in kyr) at selected depth levels, in cores of set I and set II, and comparison with K-scale ages (based on climatic record)

Depth (cm)	Set I	K-age (Δ)	Set II
1	4.1 ± 0.8	0.5 (3.6)	4.6 ± 0.5
8			7.0 ± 0.9
19	10.9 ± 0.6	9 7 (1.2)	13.3 ± 1.1
25	14 4 ± 1.4	12.8 (1.6)	18.0 ± 0 9
31	18.1 ± 1.5	15.9 (2.2)	

K = 10.2 kyr; M = 9.5 kyr; Δ = difference between set I age and K age.

Table 2 Radiocarbon ages (in kyr) of bulk carbonate and coarse fraction in INMD 115 Bx

Depth (cm)	Bulk age	Coarse fraction	Fine fraction*
0–2	4.85 ± 0.17	2.24 ± 0.11	5.62
7–9	7.87 ± 0.12	6.90 ± 0.13	8.11
19–21	14.17 ± 0.19	11.4 ± 0.17	14.93

* Fine fraction calculated (based on % carbonate and % sand): carbonate, 90.7, 91.4, 89.5; sand, 20.7, 18.3, 19.4.

We now consider the land-based timescale of climatic change for deglaciation and the Holocene to date our isotope signal (Fig. 1*a*). The resulting timescale should be younger than the corresponding deep-sea radiocarbon ages, by an amount comparable to the difference between bulk- and coarse-fraction ages. Of course, the line-up of climatic changes on the land and in the sea should match closely.

Figure 1*a* is derived from stacking the signals of cores 97, 101 and 104 (Fig. 1*b*). The shape of the isotope signal is very similar to one published earlier, from the same region, based on Albatross cores[22], but without age control. The radiocarbon measurements suggest an age near 11 kyr for step 2 (point X). According to our argument, this age represents a maximum for this climatic event. The most nearly synchronous and also the younger event on land, marking a time of rapid change from cold to warm conditions, is represented by the transition from the Younger Dryas cold period to the Preboreal warm interval. Thus the 'cold spot' preceding step 2 in our signal is fixed as the Younger Dryas, which is centred on 10.5 kyr. The entire timescale is now derived by assuming zero age for the surface, and linear sedimentation rate to the Younger Dryas fix-point. With this assumption, an excellent fit is obtained with the Norden timescale[23], based on Scandinavian climatic history (Fig. 1). The differences between the set I ages and the ages found by climate correlation are of the expected magnitude (except for the benthic mixed layer proper) (Table 1, third column).

Our new timescale puts the start of deglaciation just after 14 kyr BP (instead of 15 kyr, based on raw ^{14}C data). Step 1 is centred on 13 kyr and step 2 on 10–9.5 kyr. Our deglaciation steps compare favourably with the micropalaeontological 'warming' steps of Ruddiman and McIntyre[10], established for the northern Alantic. The correlation of the deglacial pause with the Younger Dryas, a major cold event on land, was previously suggested by Duplessy *et al.*[6]. The end of the pause is at point "K", which is taken to be 10.2 kyr BP. This event fixes our timescale, by linear interpolation and extrapolation. Point K slightly predates the Ash Layer 1 of Ruddiman and McIntyre[24], dated at 9.8 kyr BP in ref. 6.

We refer to the timescale adopted in Fig. 1 as the 'K-scale'. Its veracity ultimately rests on a climatic correlation (hence K for Klima), namely, the fit of the pause between the two deglaciation steps to the Younger Dryas cold period. This correlation was first suggested to us by Johnson[25].

Major questions arising from the new deglaciation scale are: what is the positive feedback mechanism which was responsible for the steepness of the two steps; why did deglaciation pause halfway through its completion; and is the published information for ice retreat on land compatible with the deep-sea oxygen isotope record when dated in the manner shown? The evidence for pulsed meltwater input, combined with the short timescale advocated here, makes it likely that the sought-for feedback mechanisms involved intermittent slowing of vertical ocean mixing (the 'Worthington effect')[26]. Such slowing would affect the carbon dioxide content of the atmosphere[27], and hence the direction and the rate of climatic change. There is one possible way the 'early-deglaciaton' timescale[10,15] could be resurrected: if it could be shown that lack of carbonate production (for example, owing to a meltwater lid) produced a carbonate hiatus in the crucial period, near 15–16 kyr, so that a planktonic isotope signal was not recorded, even in the equatorial Atlantic.

We thank L. Labeyrie, E. Olausson, J. Kennett, N. Shackleton and M. Sarnthein for discussions. Our research on anomalous radiocarbon dates in deep-sea sediments is supported by the US Office of Naval Research contract N00014-80-C-0440, and our isotope work by NSF grant OCE82-19553.

A prehistoric calendrical site in Argyll?

E. W. MacKie*, P. F. Gladwin† & A. E. Roy‡

* Department of Archaeology and Anthropology, The Hunterian Museum, University of Glasgow, Glasgow G12 8QQ, UK
† 'Braigh Varr', Minard, Argyll PA32 8YB, UK
‡ Department of Astronomy, University of Glasgow, Glasgow G12 8QQ, UK

The hypothesis that many prehistoric standing stone sites in Britain were set up, in relation to natural horizon marks, as astronomical observing instruments has been controversial for the past two decades. Although based primarily on statistical arguments, whether or not it stands will depend on the outcome of practical tests; it must prove able to predict at some sites the occurrence of archaeological features which can then be found by excavation. We report here on the findings at Brainport Bay in Argyllshire of artificial features pointing towards the midsummer sunrise that have been dated suitably early and of another feature indicating alignment towards the sunset at the equinox, that was first predicted and then discovered. These results seem to provide strong support for Thom's hypothesis that calendrically useful solar markers existed in Scotland at least as early as the Bronze Age.

At Brainport Bay, near Minard on Loch Fyne, one of us (P.F.G.) discovered in 1976 a series of artificial stone structures which were first interpreted as a settlement site, but the absence of clear signs of dwellings or of midden material made an alternative hypothesis desirable. Since then, the possibility of their forming an alignment towards midsummer sunrise has been considered, which seemed to explain several hitherto inexplicable features[1,2]. The presence of flint flakes and artefacts and of shattered quartz fragments on the various parts of the site confirmed Mesolithic or Neolithic activity, but there were also much later iron objects and slag. The supposed alignment consists of three main features running from north-east to south-west, namely the 'main outcrop' (with paving on it and two lower revetted 'terraces' at its south-west end), the 'observation boulders', 9 m further south-west and, 50 m further in the same direction, the 'back platform', a few metres higher up (Fig. 1).

From between the two boulders one has a striking view north-east up Loch Fyne, and a partly artificial rock notch at the south-west end of the main outcrop (1.38 m deep and 1.30 m wide at the top) frames the only two distant peaks to be seen—Beinn Oss and Beinn Dubhcraig, 28 miles away near Tyndrum. A small socket was found immediately in front of this notch and another up at the north-east end of the outcrop; two stone slabs 1.28 m and 1.46 m long, which fit these sockets well, were

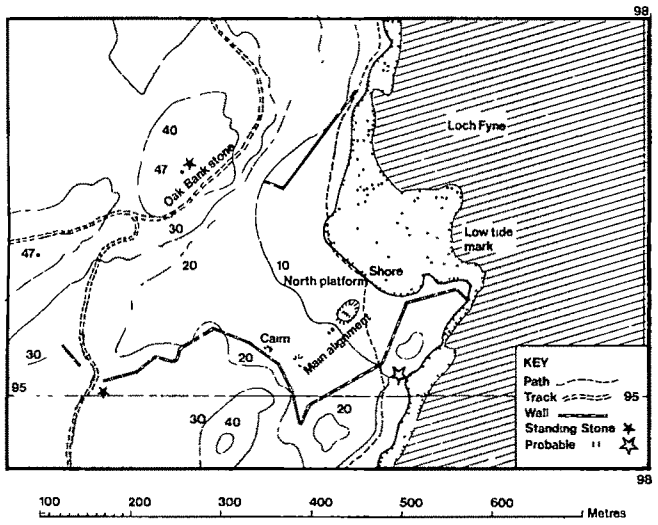

Fig. 1 General plan of Brainport Bay showing the main alignment (with the Back Platform at the south-west) and some nearby outlying features. The contours are in metres above mean sea level.

found on the buried land surface nearby. All these features—boulders, notch and sockets—lie on a straight line pointing to the mountain peaks behind which the midsummer Sun rises (see Fig. 3.5 in ref. 2). The arrangement looks like the sights of a huge rifle aimed at the solstitial Sun, but to be of practical as opposed to ceremonial use, the cleft between the two peaks would have to have been used. Measurements by Thom showed that this cleft has a declination of +23°22′, slightly before the solstice of 1800 BC; then it would have marked the upper limb of the Sun rising on two occasions about 32 days apart, before and after midsummer (see p. 134 and Fig. 3.8 in ref. 2).

The third element in the alignment, the back platform, consists of a rock outcrop on the northeastern edge of higher ground and that has been modified with revetting and paving; there is a broad flat area behind it. From here there is a dramatic, though generalized, view of the midsummer dawn, but not through the rock notch, which is now too low.

Excavations in 1982 revealed a buried sandy soil behind the back platform on top of which were struck flint flakes; a ^{14}C date of 1060±80 BC (GU 1705) was obtained for charcoal associated with the flints, equivalent to the fourteenth century BC in calendar years[3]. The revetted edge of the larger terrace next to the main outcrop was found to lie on the same buried soil (Fig. 2). Thus, the artificial elements of the main alignment have been fairly securely dated to the mid-second millennium BC or earlier. Excavations at the 'observation boulders', however, showed that, contrary to previous belief (see p. 134 and plate 3.6 in ref. 2), these have been in position since the time of the post-glacial high sea level, well before Neolithic times.

As it does not point exactly at the solstice, the calendrical function of the main alignment had to remain speculative, unless another clearly-indicated and reasonably precise alignment could be identified nearby; this could serve as a double check on any solar calendar and would tend to confirm that one was in use. The most probable candidate for a second alignment was the fallen stone on the ridge above Oak Bank, ~240 m north-west of the main alignment.

An attempt in 1981 to discover whether the Oak Bank stone could have been an artificial foresight to mark the midsummer sunset, as seen from the large terrace, resulted in the discovery, as a potential backsight, of the small stone North Platform a few metres north of the main outcrop and in the appropriate position; excavations in 1982, however, showed it to be relatively modern. It then seemed appropriate to test whether the fallen stone on Oak Bank might itself have been the backsight for an alignment.

One of us (P.F.G.) had found previously two unusual rock carvings a few metres south-east of the fallen Oak Bank stone, among the dense firs of a Forestry Commission plantation. Each consists of a pecked cup-mark of standard early Bronze Age type, but with a straight shallow pecked groove running through it (Fig. 3). Carving no. 1 has a groove ~60 cm long, on an azimuth of 130.5/310.5°, and points directly back at the Main Outcrop below. Carving no. 2 has a groove ~40 cm long on an azimuth of ~81/261°, ~2.1° greater than the line defined by the two cup-marks themselves. These directions can be determined to within ~0.5° using a prismatic compass checked against a line of known azimuth.

The many fir trees around the carvings obscure the western and northwestern horizons; the groove of no. 1, however, was found to point at a featureless horizon several degrees to the right of the midsummer sunset position. The near east-west orientation of no. 2 suggested that it might mark an equinoctial line, the backsight for which would be the fallen stone nearby, but the eastern horizon across the loch is flat and featureless. Nothing could be seen of the western horizon at first until the azimuth of the groove was transferred 20 m to the base of the fallen stone; it then pointed almost exactly at a deep V-shaped notch ~1 km away in Siaradh Druim, the 'western ridge'. A metal rod laid in the groove of the rock carving confirmed, after some clearance of branches, that it points at this notch. This notch has an azimuth of 261°32.5′ and a declination of +0°08′ as seen from the stone (perhaps +0°04′, if the trees on the left slope are removed) (Fig. 4).

This position is within the range of the declinations of equinoctial sites identified by Thom, the mean of which is approximately at the 'megalithic equinox' of +0.51° (ref. 4). This is the date that would have resulted if the equinox was defined by counting the days in the year and sub-dividing (the summer half being a few days longer because of the eccentricity of the Earth's orbit (see p. 109 in ref. 4)). The Oak Bank alignment could have defined this megalithic equinox very well, if the Sun's lower limb served as the marker against the horizon. Figure 4 shows the 24′-wide zone of fluctuation—the amount

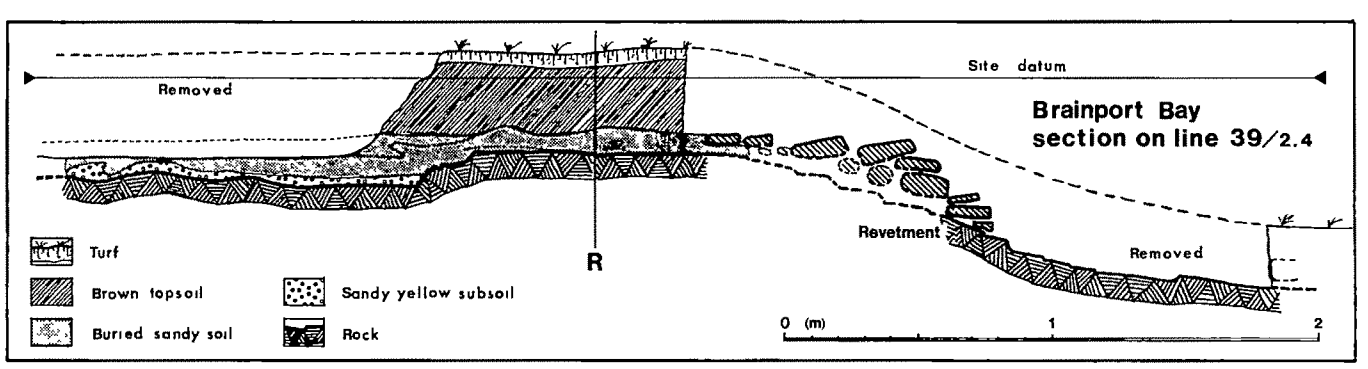

Fig. 2 Section of soil layers on the northwestern edge of the large terrace at Brainport Bay, showing the revetment of the terrace lying on the prehistoric ground surface.

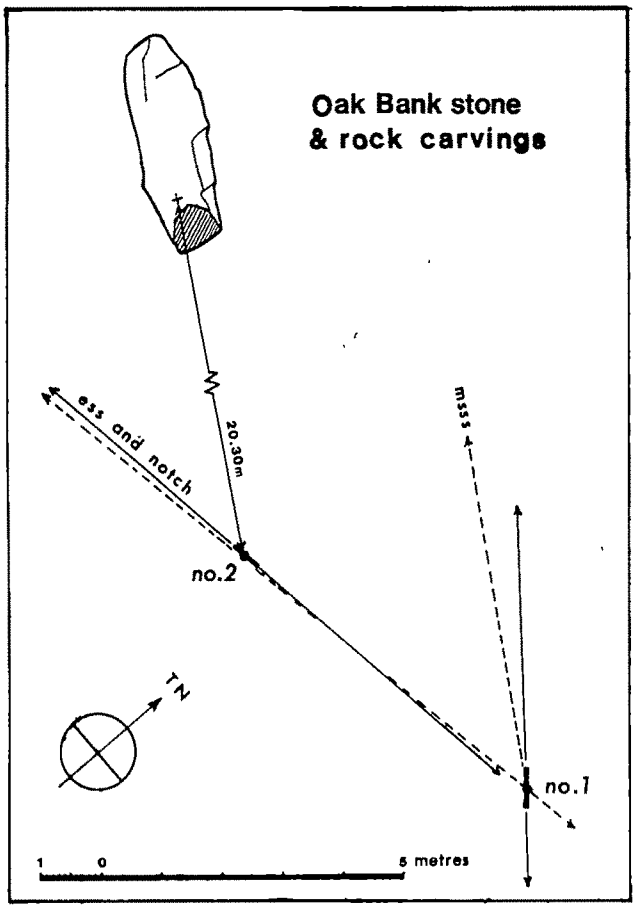

Fig. 3 Plan of artificial features on Oak Bank—the fallen stone and the two rock carvings. Carving no 1 points back to the main site at a distance of 225 m. 'ESS' means equinoctial sunset and 'MSSS' midsummer sunset.

by which the solar declination can vary at sunset at the equinoxes—against the notch. Thus, the first appearance of the full disk in the notch in the spring, and the last in autumn, would have marked the day of the megalithic equinox and the alignment could have served as a good check on a solar calendar.

Ideas about the achievements of prehistoric man in Britain have focused traditionally on his technological and economic skills, deducible directly from the archaeological evidence; ceremonial and religious practices are much harder to recover but seemed to have been suitably primitive[5,6]. However, much evidence from Thom shows that late Neolithic people erected standing stones to mark the position of the Sun and Moon (and some stars) on the horizon at important points of their cycles and that they thereby developed considerable astronomical expertise (see chapter 9 in ref. 4). These ideas have aroused considerable interest and controversy[7-11].

The particular aspect of the Thom hypotheses examined here is that many standing stones marked the 'backsights' (observers' positions) of alignments that could detect when the Sun was at the solstices, equinoxes and at other important intermediate dates of the solar calendar. These lines point towards 'foresights', which are natural marks on the horizon where the Sun rose or set at the times concerned and which are usually indicated in some way by the stones themselves.

The evidence assembled consists of a large number of standing stones, which could have been the backsights for such accurate alignments in Neolithic times, and of the statistical argument that this could not have happened by chance (ref. 12 and see chapter 8 and Fig. 8.1 in ref. 4). There has been much argument about whether such deliberately arranged astronomical lines (on which the more elaborate astronomical hypotheses developed by Thom (concerning the Moon) ultimately depend[4,13,14]) were actually intended to be such by the standing stone erectors,

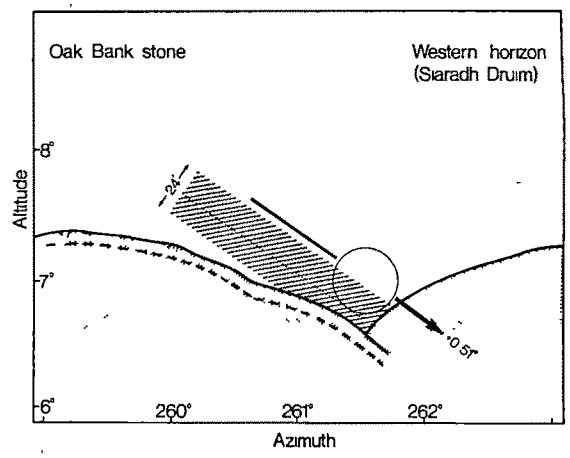

Fig. 4 Siaradh Druim, the 'western horizon', as seen from the Oak Bank stone with the Sun at the 'megalithic equinox'; the dotted line indicates where the real horizon may be, below the tree line. The shaded band shows the range of possible positions for the lower limb at sunset at that time.

about how accurate they were and for what exactly they were used[10].

It can be argued that the genuineness, or otherwise, of the alignments will only be finally settled by testing a selection of examples on the ground, that is, by finding sites where one of the astronomical alignment hypotheses predicts the existence of some feature that can then be sought by excavation[15,16]. One of us (E.W.M.) attempted to do this at the Kintraw standing stone in mid-Argyll, where an artificial platform was discovered, as required by Thom's theory that a precise midwinter sunset alignment existed there[17]. However, as the platform could not be dated, the evidence was inconclusive.

The results from Brainport Bay described here suggest that, at this site, there are two well-marked prehistoric solar alignments, the reality of which has been demonstrated beyond reasonable doubt and which could therefore be interlinked. The conspicuous line towards midsummer sunrise is formed by clearly artificial and by natural features and it has been dated as suitably early, directly, from associated artefacts and indirectly, from a ^{14}C measurement. Yet the discovery that the 'observation boulders' are natural, implies that the alignment began as the chance finding of a suitable site with a long view to the north-east (presumably by people searching for one) and that features on it were modified to form a line towards the midsummer sunrise. This could explain why the 'foresight' mountains, though suitably distant, are not the ideal shape for marking the solstitial sunrise exactly; in other such cases, the Sun's upper limb rose or set along one slope, about parallel to the angle of its diurnal movement (see Fig. 12.2 in ref. 4).

This in turn suggests that the prominent north-east alignment was intended as much for ceremonial as for calendrical purposes; certainly the dawn spectacle is dramatic and could have been viewed by many people. It may also have been a useful calendrical alignment; the date of the solstice could have been found at any period in the past by halving the interval between successive risings in the notch. However, such an indirect alignment is less convincing statistically than one that points exactly at the solstitial declination, hence the search for a second solar line at the site.

Such a solar line, indicating the equinoctial sunset, was found at the Oak Bank stone rock carvings. Because of the obscuring fir trees it is also a good example of the discovery of a convincing alignment through a prediction made from Thom's general solar alignment hypothesis. On such independent testing of potentially accurate astronomical alignments as this depends surely the fate of ambitious re-assessments of the skill and organization of late Neolithic society in Britain[18], and indeed that of the traditional views also[5,6].

We thank the Forestry Commission (Scotland) and, since 1983, Lt Col. R. Gayre of Gayre and Nigg, Minard Castle, for permission to survey and excavate at the site. We also thank the following who assisted at the site: Dr and Mrs J. R. Baker, Mr J. Birdsey, Mr M. Davis, Ms Helen Dyson, Mr H. N. Hawley, Mr H. E. Kelly and Mr S. White. The Director General of the Ordnance Survey is thanked for permission to use the 1:10,000 Ordnance Survey map as the basis for Fig. 1 (Crown copyright reserved).

The first pre-Rhaetic therian mammal

N. C. Fraser, G. M. Walkden & V. Stewart

Department of Geology, Marischal College, University of Aberdeen, Aberdeen AB9 1AS, UK

The earliest mammals in the fossil record are recognized by their multicusped and multiple-rooted cheek teeth, and in south-west Britain they appear abruptly in sediments that postdate the Rhaetic transgression at ~200 Myr. Here we report the discovery of teeth of the primitive mammal *Kuehneotherium* in a terrestrial fissure deposit from the Mendip Hills (Somerset, UK) that predates the Rhaetic transgression. The teeth were found in the sediment fill of a collapsed cave[1] at Emborough near Wells during the systematic reinvestigation of a number of late Triassic vertebrate sites. The assemblage is otherwise typically pre-Rhaetic and includes the gliding lizard *Kuehneosaurus*. The finding of mammalian remains throws doubt on the fundamental distinctiveness of pre-Rhaetic and post-Rhaetic vertebrate faunas.

Vertebrate-bearing fissure deposits are known at several sites in the Lower Carboniferous/Mesozoic unconformity either side of the Severn Estuary (Fig. 1). The fissures comprise a variety of features including karstic cave systems, tectonic joints and faults; their fills range from Triassic continental red marls to middle Jurassic marine limestones. In the first major review of the nature and occurrence of fissure deposits, Robinson[1] distinguished between Norian and Rhaeto-Liassic deposits which she believed could be recognized on the basis of their vertebrate faunas[2]. The Norian fauna consisted entirely of sauropsids whereas the Rhaeto-Liassic faunas contained theropsids and mammals in addition to sauropsids. There was also some variation in the nature of the sauropsid fauna, particularly with respect to archosaurs, which occurred only rarely in the Rhaeto-Liassic deposits. This broad division has been accepted by subsequent authors. Typical Norian assemblages include *Clevosaurus*, *Kuehneosaurus*, *Planocephalosaurus*, primitive crocodiles and pseudosuchians[3–5], whereas the Rhaeto-Liassic forms include *Morganucodon*, *Kuehneotherium* and the lepidosaur *Gephyrosaurus*[6–8].

More recently, Marshall and Whiteside[9] have identified marine Rhaetian palynomorphs in sediments at Tytherington Quarry which contain a typical Norian sauropsid fauna, including *Clevosaurus* and *Planocephalosaurus*[10]; this work did not question the existence of two distinct faunas, but threw doubt on the validity of assuming an age prior to the Rhaetic transgression for the sauropsid assemblages. We have confirmed the presence of datable palynomorphs in the Tytherington sequence, but their usefulness is open to question as the deposits are contained within tectonically generated fissures which have suffered more than one phase of disturbance and mixing of the contents.

The Emborough deposit has yielded no palynomorphs and cannot be dated in this way, a problem in common with late Triassic continental sediments elsewhere[11]. The deposit consists of a single large pocket of poorly sorted, locally derived limestone boulders and coarse conglomerate set in a matrix of red marl. The pocket has been interpreted as a collapsed cave deposit[1], and the conglomerate and marl components are typical pre-Rhaetic lithotypes; no Rhaetic or post-Rhaetic clastic components can be recognized. Further evidence of the pre-Rhaetic age of the Emborough deposit is provided by nearby outcrops of basal Rhaetic sediments which overlie a formerly planar transgression surface. This surface now rises southwards, and clearly extended across the top of the Emborough pocket.

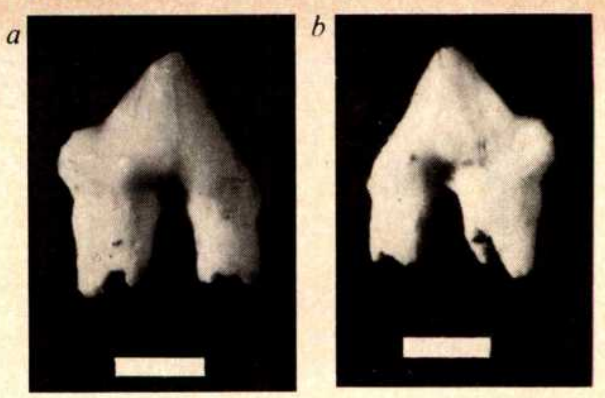

Fig. 3 A premolariform tooth of *Kuehneotherium* (AUP no. 11134). *a*, Buccal; and *b*, lingual view. Scale bar, 0.5 mm.

Following Robinson[1], therefore, we are certain that the Emborough pocket is Norian in age.

The reptilian fauna of Emborough consists of lepidosaurs and archosaurs, and by far the most abundant of these is the gliding lepidosaurian, *Kuehneosaurus*[12]; this genus has also been identified at Cromhall[4] and Pant-y-ffynon[13], although in much smaller numbers. Both of these localities are regarded as pre-transgressional in age[4,14] and the genus is not known at the Rhaeto-Liassic localities.

We have confirmed an abundance of *Kuehneosaurus* at Emborough and have noted sphenodontids. Of the two mammalian teeth, the best preserved (Fig. 2, AUP no. 11133) closely resembles a lower molar of *Kuehneotherium*, but with relatively low central cusps. Molariform teeth of *Kuehneotherium* were first described in detail by Kermack *et al.*[7], who noted that in the lower molars the central cusps were generally elevated and higher than in the upper teeth. However, in one lower left molar described by Kermack *et al.*[7] (BMNH C.855), the cusps are rather less elevated. The best-preserved Emborough tooth is practically identical in this and other respects, indicating beyond doubt that it belongs to the lower left mandible. The second Emborough tooth (Fig. 3, AUP no. 11134) is a premolar showing more polish than the first and it exhibits a well-defined wear facet. Kermack *et al.*[7] emphasized that the premolars of the early mammals showed insufficient characters for a single tooth to be referable to a particular genus, citing the similarity of *Kuehneotherium* premolars to those of *Eozostrodon*. However, the occurrence of the distinct *Kuehneotherium* molar in the deposits indicates that in this instance the Emborough premolar is most probably also from *Kuehneotherium*.

This new record of *Kuehneotherium* from Emborough is important for two reasons. First, it is undoubtedly the earliest record of a therian and may even be the oldest fossil mammal. It predates the kuehneotheriid, *Woutersia*, and the morganucodontid, *Brachyzostrodon*, described by Sigogneau-Russel[15] from the French Rhaetic locality of Saint-Nicholas-de-Port. Although haramyid teeth have been described from earlier deposits, namely the Uppermost Middle Keuper of Halberstadt[16], very little is known of this taxon. While they may be non-therian mammals, considerable doubt remains[17-19] and their systematic position cannot be readily resolved within the framework of early mammals. From an analysis of the tooth wear facets of haramyids, it has been suggested that they may have had an antero-posterior movement of the lower jaw akin to that of the cynodont reptiles[18,19]. Although this group of reptiles is widely accepted as being ancestral to the mammals, both prototherian and therian mammals have a lateral-medial motion of the lower jaw.

Second, the finding of a mammal in deposits with 'typically' Norian assemblages raises serious doubts about the validity of distinctions drawn between pre-transgression and post-transgression terrestrial vertebrate faunas. Although differences in the faunas can be recognized, these may now be no more significant than those between localities of the same age, or even between different sites at the same locality[4].

It seems likely that ecological factors played an important part in determining these assemblages, in particular, feeding habits may have been a factor responsible for mammalian expansion at this time. From the nature of its dentition, *Kuehneotherium* was undoubtedly an insectivore[6,20] but so too were several of its contemporary lepidosaurs[4,8]. This raises the possibility of direct competition, but the reasons for the proliferation of the mammals in Rhaeto-Liassic times need not be related to this, nor were environmental factors connected with the Rhaetic transgression necessarily involved. By means of their implicit endothermy[21], the early mammals such as *Kuehneotherium* may have avoided direct competition with other insectivores by adopting a nocturnal niche.

AUP and BMNH are abbreviations for Aberdeen University Palaeontology and the British Museum (Natural History) collections, respectively. We thank Dr D. J. Batten for palynological advice and Professor K. A. Kermack for his comments on the mammalian teeth. We also thank Mr J. Blatchford for allowing us access to Emborough Quarry. The work presented here forms part of a wider reinvestigation of late Triassic fissure faunas supported by NERC grant GR3/4419, which we gratefully acknowledge.

Reduction of oak fecundity by low-density herbivore populations

Michael J. Crawley

Imperial College at Silwood Park, Department of Pure and Applied Biology, Ascot, Berks SL5 7YP, UK

Explanations for the low levels of defoliation in natural woodlands[1–6] have assumed that insect herbivores have a negligible effect on plant fitness and demography[7,8], perhaps because of plant compensation[9–11]. Levels of defoliation between 5 and 15% are typical, and are attributed variously to the impact of natural enemies, inclement weather and low food quality in keeping herbivore populations at low densities[12,13] (but see refs 14, 15). Here I report the results of a 4-yr study in which matched pairs of oak trees, *Quercus robur*, were sprayed regularly to exclude all herbivorous insects; despite the fact that the unsprayed trees lost only 8–12% of their leaf area, the sprayed trees consistently produced more seeds (from 4.5 to 2.5 times the numbers on unsprayed plants). It is not known whether this substantial reduction in seed production actually leads to a reduction in plant recruitment. It does seem, however, that plant compensation is not fully effective against low-density herbivore populations and, therefore, that slight differences in the level of defoliation between plants may cause important differences in plant fitness.

All invertebrate herbivores were excluded from six pairs of oak trees (matched initially for size, age and date of bud-burst, ranging in girth from 14 to 97 cm). I applied a mixture of contact (permethrin) and systemic (dimethoate) insecticides in a water base, and sprayed the control trees with an identical volume of water. The sprayed trees were further protected by a sticky band around the trunk which excluded walking insects such as the wingless females of the winter moth, *Operophtera brumata*. The sprays were applied monthly from March to September (but every 2 weeks in May and June), at a rate of between 1.5 and 5.5 litres per tree (~500 g active ingredient per hectare). There is no evidence of phytotoxic effects of the spray on the plants, nor is there any suggestion that these particular insecticides act as promoters of flowering or seeding in trees[16]. Regular counts using a variety of methods were made of insect herbivore numbers on nearby trees[17].

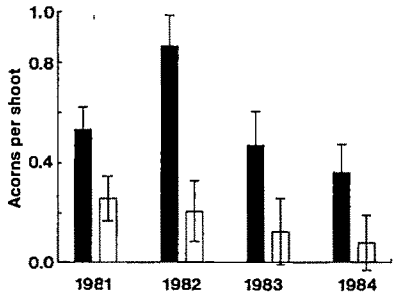

Fig. 1 Number of acorns per shoot on sprayed (solid bars) and unsprayed (open bars) trees in each of 4 yr. The data represent arithmetic means and 5% least significant differences, based on separate 2-way analyses of variance for each year (main effect means calculated over three size classes with two replicates in each class, using the same 12 trees each year).

The numbers of male and female flowers per shoot were assessed from a non-destructive sample of 100 randomly selected shoots per tree in June; defoliation levels, primary and lammas shoot lengths[7] and acorn crop were assessed from a separate sample of 100 shoots in August each year (Table 1).

Insecticide treatment was effective in all years in reducing defoliation levels below 5% and in virtually eliminating gall-forming and sap-sucking insects. Reduced herbivore numbers had no effect on primary or lammas shoot growth, trunk-wood growth or flower production in the following year (Table 1), but led to a significant increase in acorn production (Fig. 1). A variable number of acorns on unsprayed trees were attacked by the gall-forming wasp, *Andricus quercuscalicis* (ref. 18 and R. S. Hails and M. J. C., in preparation). As seen in Table 1, the increase in acorn crop under spraying is not simply an artefact of excluding the gall-former.

In a separate study of 36 trees with girths ranging from 30 to 600 cm, there is no correlation between defoliation and acorn production either within trees (that is, from shoot to shoot) or between trees, in any year of this study. Failure to detect significant depression in fecundity results from the very high tree-to-tree variance in acorn production, and from the fact that certain trees are consistently the most heavily defoliated (the correlation between defoliation in year t and in year $t+1$ is significant for all pairs of years; $n=36$, $r>0.34$, $P<0.05$). Here, the failure to detect subtle ecological effects demonstrates the importance of manipulative field experiments in studies designed to elucidate the role of herbivores in plant population dynamics and as agents of natural selection.

Arithmetic means for six sprayed (S) and six unsprayed (U) trees divided into three size classes with two replicates per size class. Numbers estimated per shoot are from 100 shoots per tree each year. Wood increment is calculated from pre (t) and post ($t+1$) growing season measurements of girth (G cm) as $\ln(G^3_{t+1}) - \ln(G^3_t)$. Significance tests were based on separate 2-way analysis of variance for each year, with two levels of insecticide treatment (+ or 0) and three size classes of trees ($G<25$, $25 \leq G<50$, $G \geq 50$ cm); NS, not significantly different. Defoliation was caused principally by *Tortrix viridana* and *Operophtera brumata* but with many less important Lepidoptera. Peduncles measured in August include fruit stalks with acorns, galls, undeveloped fruits and unpollinated flower remains; not all peduncles bear sound acorns. Galls refer to the 'knopper galls' of *Andricus quercuscalicis*

The results of the experiment described here are consistent with the hypothesis that oak is essentially a K-strategist[19,20], gaining in fitness by first ensuring its survival and by putting its carbohydrate and protein resources into seed production only when the needs of reserve-replenishment, wood growth, root growth and bud-filling have been met. Although several other studies of natural[21,22] and artificial defoliation of trees[23,24] have shown reduced seed production, these have involved typically much higher rates of defoliation (50–100%). The present study is the first to show that natural low levels of insect feeding can cause a significant reduction in seed set. As the number of female flowers produced in spring does not differ between the two treatments in most years, the increase in acorn production is seen to result from a reduction in the number of peduncles aborted and an increase in the average number of acorns filled on each surviving peduncle. There is no evidence to suggest that insects feeding directly on the flowers or young acorns contribute to the observed result.

As there is no simple relationship between seed production in one year and seedling recruitment in the next[9], we cannot be sure that these low levels of defoliation actually affect plant population density. This study does emphasize, however, that it is incorrect to assume that 'typical' low density populations of defoliating and sucking herbivores can have no impact on the demography of the tress. Also, given the great variation from tree to tree in average defoliation levels and the magnitude of the differences in fecundity observed in this experiment, these relatively scarce herbivores may act as potent agents of natural selection.

I thank Dr George McGavin for help with the field work.

Firing patterns of motor units in normal rats

Rune Hennig & Terje Lømo

Institute of Neurophysiology, University of Oslo, Oslo 1, Norway

Skeletal muscles consist of motor units which may differ considerably in contractile properties and types of usage. Some units participate mainly in relatively rare, quick movements and contract rapidly and are easily fatigued (type FF); others contribute to the maintenance of posture and hence contract slowly and are fatigue-resistant (type S), while others are both fast and fatigue-resistant (type FR; ref. 1). Our understanding of motor control mechanisms and the dependence of contractile properties on usage would be enhanced if more quantitative information were available[2–4] concerning the firing patterns of individual motor units during normal motor behaviour. Therefore, we have made continuous recordings for extended periods from single motor units in the fast extensor digitorum longus (edl) and the slow soleus (sol) muscle of freely moving adult rats. By counting the total number of discharges for each unit, and by determining the distributions of interspike intervals and the duration of the individual impulse trains, we have obtained information about firing rate, amount of use, modulation of muscle force and tonic and phasic behaviour for 16 motor units. We now report that these units fall into three classes apparently corresponding to type FF and FR in the edl muscle and type S in the soleus muscle.

Figure 1*a–c* shows representative discharges from two units in edl (*a* and *b*) muscle and one unit in soleus (*c*) muscle. The unit potentials were similar in shape and amplitude throughout the 24-h recording, and superimposing the traces indicated that they originated from one unit only (Fig. 1*d–f*). In Table 1 the units have been ordered according to the percentage of total time that they were active. Three classes of firing patterns can be discerned. In the first class (edl-1 units) the units were active for only 0.5–3 min per 24 h (0.04–0.22% of the total time). In the second class (edl-2 units) the total active time was 23–72 min (1.6–5%), and in the third class (sol-1 units), 5.3–8.4 h (22–35%). The soleus units formed a separate class by firing more impulses at a lower frequency (~20 Hz) than any edl units. The two classes of edl units could not be clearly distinguished on the basis of firing rate alone, although, on the whole, edl-1 units fired at higher frequencies than edl-2 units (Fig. 2, Table 1). The edl-1 units, however, were by far the least active units, generating impulse trains that were always brief and in 70–80% of cases started with a pair of spikes having a short interspike interval (initial doublet of Fig. 1*a*, *d*). In some respects edl-2 units occupied an intermediate position in that they resembled edl-1 units by firing at high frequency and sol-1 units by generating a large number of impulses which sometimes occurred as long trains of impulses.

The firing pattern of soleus units was relatively uniform. There was some variation between units in amount of activity, but little variation in median firing rates. This pattern probably represents S-type motoneurones innervating slow, fatigue-resistant type I muscle fibres which make up the large majority of fibres in adult rat soleus muscle[5]. The edl muscle contains almost exclusively fast motor units[6]. When stained for myosin ATPase activity, approximately half the muscle fibres appear as type IIA and the other half as type IIB[7], which, in general, correspond to FR and FF units, respectively[1]. It seems likely, therefore, that the infrequently used edl-1 units represent FF units, whereas the much more frequently used edl-2 units correspond to FR units.

There exists evidence that motor unit characteristics are more continuously distributed than is suggested by Table 1 (refs 1, 8). The clear separation between soleus and edl units is not surprising given such widely differing muscles. Within the edl, however, a larger unit sample would probably have narrowed the gap between the two classes of firing patterns, and the existence of intermediate types cannot be excluded. Nevertheless, even within the three classes of firing patterns presented in Table 1, there is considerable variation in the number of discharges and in the frequency of spikes within each discharge—this variation may partly explain the variation in contraction speed and metabolic enzyme activity observed in different motor unit types and in type I, IIA and IIB fibre populations[1,9,10].

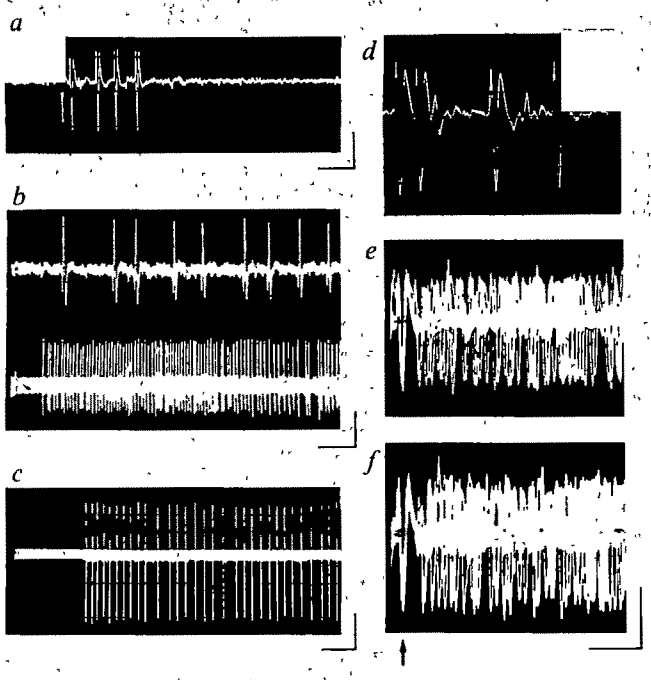

Fig. 1 Typical discharges for each of the three classes of motor units shown in Table 1: *a*, edl-1 unit; *b*, edl-2 unit; *c*, sol-1 unit. Traces *d*–*f* show that it is possible to record continuously for 24 h from one motor unit (in this case an edl-1 unit). Spontaneous action potentials trigger the oscilloscope trace and are displayed after a fixed delay (arrow) on a single trace (*d*) or on ~100 superimposed traces (*e* and *f*). The action potentials have a similar appearance at the beginning (*e*) and at the end (*f*) of the 24-h recording. Note that there is also a minimum spike interval after the first triggered spike in each of the traces in *e* and *f*, which makes the presence of more than one unit highly unlikely. Vertical bars represent 0.5 mV and horizontal bars 20 ms (*a*, *b*), 200 ms (*b*, *c*) and 10 ms (*d*–*f*). The motor unit potentials were similar in amplitude (0.5–1 mV) to fibrillatory potentials recorded from the same electrodes 2–3 days after cutting the sciatic nerve, indicating that the potentials were generated by single muscle fibres close to the recording electrodes.

Methods. Adult male Wistar rats were anaesthetized with chloral hydrate and pentobarbital (Equithesin, 0.4 ml per 100 g). Four Teflon-coated platinum wires (outer diameter 0.25–0.50 μm), soldered to the ends of four flexible Teflon-coated multi-stranded steel wires, were guided by a thin needle and tube longitudinally into the centre portion of the edl or sol muscle. The distance between each cut end was ~100 μm. The steel wires continued under the skin, through an attachment fixed to the skull by screws and dental cement, into a flexible protective tube which connected the rat to rotating contacts and preamplifiers above it. Muscle action potentials were recorded between the ends of the two wires that gave the best spike isolation and signal-to-noise ratio. The action potentials were stored on tape, and reproduced later on a storage oscilloscope for examination of the entire 24-h recording. Only potentials that could be attributed confidently to the same unit for the entire 24-h period were accepted for further computer analysis. The recordings were usually best 2–3 days after implantation; thereafter, the potentials often declined in amplitude, but with occasional improvements. Such changes made it difficult to be sure that we were recording from the same unit for periods much longer than 24 h. From the time of implantation the rats were kept in the laboratory in large buckets where they moved freely, were more active during the night and showed apparently normal behaviour in terms of movement, feeding and sleeping.

If we are justified in assigning the firing patterns of edl-1, edl-2 and sol-1 units to FF, FR and S-type motor units, some interesting relations between firing pattern and contractile properties appear. First, low firing frequency characterizes slow motor units, whereas high firing frequency characterizes fast motor units. Second, motor units that are used frequently are more fatigue-resistant than those used infrequently. Third, motoneurones fire naturally at frequencies that give maximum control over the tension developed by the muscle fibres. Figure

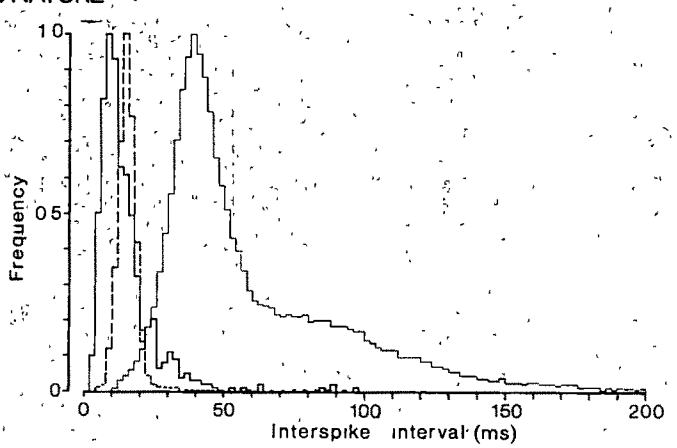

Fig. 2 Normalized frequency distribution of the interspike intervals obtained during a 24-h recording from the units shown in Fig. 1*a*–*c*. The thick solid line shows the distribution for the edl-1 unit; broken line, the edl-2 unit; and the thin continuous line, the sol-1 unit. The histograms contain, respectively, 686, 1,223 and 91,097 intervals and are typical of the three classes of motor units shown in Table 1. Intervals longer than 200 ms, representing only a very small fraction of the total, have been omitted. From such histograms, an impulse train was defined as starting (and stopping) when the duration of the preceding (and subsequent) intervals was at least 200 ms for edl units and 500 ms for sol units; this definition ensured that the tension produced by any preceding impulse declined to zero before another train was said to start.

3*a* shows the tension developed by stimulating soleus and edl muscles at different frequencies. In soleus muscle twitches begin to fuse at ~8 Hz and maximum tetanus is reached at ~100 Hz. In edl, similar force summation occurs between 30 and 200 Hz. The natural firing rates of soleus and edl units (Fig. 3*b*) show a striking correspondence to the rising portions of their respective tension–frequency curves (Fig. 3*a*), which cover the frequencies over which muscle force can be effectively modulated.

These relationships support recent evidence that the pattern of evoked muscle activity has an important role in the regulation of speed of contraction and fatigue resistance[11,12]. Thus, a large amount of low-frequency (10 Hz) stimulation of the nerve induces both slow contraction speed and high fatigue resistance in fast muscles[13,14]. Conversely, the slow soleus muscle contracts much faster when denervated and stimulated at high frequency (ref. 15 but see also ref. 11) and becomes less fatigue-resistant if the amount of stimulation is kept low[16]. Similar, but less pronounced, speeding up occurs if the nerve to the soleus is intact and the muscle continues to show tonic low-frequency activity in between the high-frequency stimulus trains (T.L. and R.H., unpublished). Mechanisms appear to exist, therefore, whereby the contractile properties of muscle fibres can be adjusted continually to the pattern of afferent impulse activity. Thus, effective performance can be maintained throughout life despite changes in the level and pattern of activity.

Certain features of the edl-1 firing pattern deserve special mention. First, edl-1 units rarely generated more than five or six impulses at a time: a single impulse was by far the most common event, two impulses per burst the next common event and so on. By varying the number of stimuli from 1 to 5 in a train of stimuli to the edl muscle, we found that the force output can be varied between ~15% and 80% of maximal tetanic tension. Hence, the force output of the motor unit must normally show considerable variation as a result of the observed variation in number of motoneurone discharges per burst. Second, although the total number of impulses in edl-1 units was 1–2 orders of magnitude lower than in edl-2 or sol-1 units, the edl-1 units nevertheless discharged trains of impulses on hundreds or thousands of occasions per day. Assuming that the edl-1 units are FF units, this suggests that FF units participate not only in relatively rare, high-force quick movements such as jumping,

Table 1 Firing patterns of individual motor units in the rat

Motor unit	Amount of activity		Burst characteristics			
	% Time occupied by bursts	No. of impulses per day	First interval (Hz)	All intervals (Hz)	No. of impulses per burst	Longest duration (s)
edl-1	0.04	2,600	250 (333–167)	91 (111–58)	3 (1–18)	0.83
	0.07	4,600	167 (333–125)	83 (111–67)	3 (2–16)	1.15
	0.09	5,600	143 (200–77)	77 (91–67)	13 (3–35)	3.9
	0.14	7,800	125 (200–77)	77 (83–53)	5 (2–12)	1.1
	0.22	11,200	91 (167–63)	67 (77–50)	4 (1–8)	1.15
edl-2	1.6	105,500	71 (125–46)	83 (100–67)	3 (1–11)	59
	2.0	89,500	50 (100–40)	53 (59–50)	25 (3–65)	120
	2.6	119,200	43 (56–30)	56 (67–40)	6 (2–18)	141
	3.5	139,400	36 (44–26)	48 (53–42)	4 (2–13)	89
	5.0	243,100	41 (67–29)	58 (67–53)	39 (6–56)	135
sol-1	22	309,500	13 (23–7)	21 (26–12)	5 (1–35)	300
	29	449,500	14 (24–6)	19 (26–14)	8 (1–39)	390
	31	453,400	14 (29–6)	19 (29–14)	7 (1–38)	548
	31	446,400	14 (25–6)	19 (23–13)	9 (1–35)	290
	32	482,500	15 (31–5)	21 (26–15)	10 (1–40)	510
	35	495,800	14 (23–6)	18 (25–13)	7 (1–36)	490

Columns 4 and 5 give median values for the instantaneous frequencies for certain intervals in all the bursts generated by one motor unit in one day. Column 4 refers to the first interval and column 5 to all intervals in each burst. Note that only in the edl-1 units is the frequency highest at the onset of a burst, in agreement with the frequent occurrence of initial doublets in these units (Fig. 1*a*, *d*). Numbers in parentheses are quartile values.

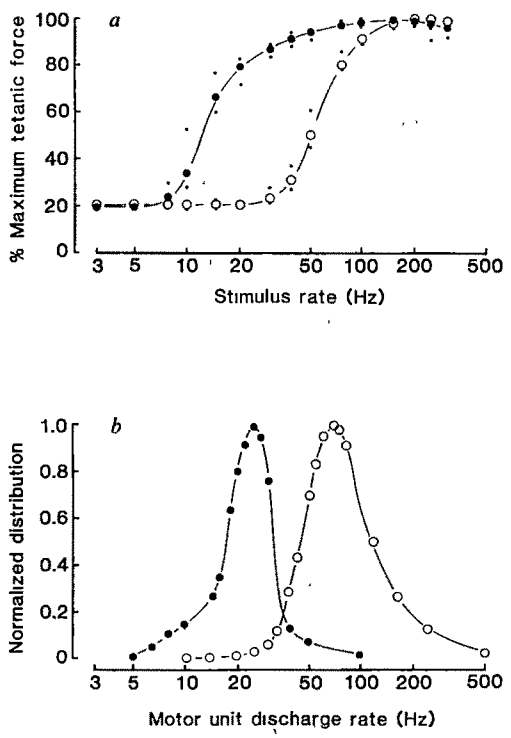

Fig. 3 Correspondence between tension-frequency curves (*a*) and motor unit firing rate (*b*) in soleus (●) and edl (○) muscles. The tension-frequency curves were obtained in acute experiments *in situ*, at 35 °C and at optimal muscle length by stimulating supramaximally the nerves to normal soleus and edl muscles. Each symbol represents the median isometric tension obtained from eight (sol) or six (edl) muscles and represents the highest tension produced regardless of when this occurred during a 1-s stimulus train at the frequencies indicated. Total ranges that extend beyond the symbols are indicated by dots. The curves in *b* were obtained from histograms of the type shown in Fig. 2 for all the units shown in Table 1. Each histogram was divided into segments of 5-ms duration, and the number of interspike intervals within each segment were counted, converted to frequency by taking the reciprocal values and expressed relative to the most commonly occurring frequency for all 6 units in soleus muscle and 10 units in edl muscle.

but also in more frequent, brief, inconspicuous contractions, possibly of a corrective nature, such as those described for high threshold units in humans[4]. The total amount of activity in edl-1 units, expressed as average firing rate over ⩾1 day, was only 0.03–0.13 Hz (Table 1). Even lower mean impulse rates prevent supersensitivity to acetylcholine and other abnormal responses in denervated muscles if the activity is evoked relatively often by direct stimulation, for example, by a brief 100-Hz stimulus train applied every 2 h (mean frequency 0.01 Hz; refs 16, 17 and unpublished observations). In contrast, denervated organ-cultured muscles, which fibrillate relatively intensely for ~20 h, then remain silent for 2–3 days before a new cycle is repeated, show much higher average firing rates (~1 Hz) and yet become both atrophic and supersensitive to acetylcholine[18]. This suggests that timing, rather than the amount of activity, is important for the maintenance of normal muscle function. The relatively frequent activation of edl-1 units may explain, therefore, why FF units retain normal properties despite high activation thresholds[19] and low total amounts of activity.

Stimulation of food intake in rats by centrally administered hypothalamic growth hormone-releasing factor

F. J. Vaccarino*, F. E. Bloom, J. Rivier†, W. Vale† & G. F. Koob

Department of Basic and Clinical Research, Scripps Clinic and Research Foundation, 10666 North Torrey Pines Road, La Jolla, California 92037, USA
† Peptide Biology Laboratory, The Salk Institute for Biological Studies, PO Box 85800, San Diego, California 92138, USA

Hypothalamic growth hormone-releasing factors (GRFs) have been purified recently from human pancreatic (hp) tumours[1,2] and from rat hypothalamus (rh)[3]. GRF peptides have strong homology with peptides of the glucagon, vasoactive intestinal polypeptide and PHI-27 family. Aside from their potent actions on release of somatotropin, no other biological actions of GRFs have been reported. GRF has been localized in neurones bordering the ventromedial hypothalamic nucleus (refs 4, 5; L. Swanson and P. Sawchenko, manuscript in preparation), a region associated frequently with experimental analysis of feeding behaviour[6]. We now report that intracerebroventricularly (i.c.v.)-administered rhGRF and hpGRF(1–40) in doses of 0.2, 2.0 and 20.0 pmol, produced an increase in food intake in hungry rats. This effect seemed to be specific to GRF as i.c.v. injections of a structurally related but physiologically inactive peptide[7] in the same doses had no effect on feeding. In addition, peripheral injections of rhGRF or growth hormone had no effect on food intake, suggesting that the present effects may be mediated centrally. Injections (i.c.v.) of rhGRF (0.2, 2.0 and 20.0 pmol) had no effect on general activity, suggesting that GRF does not produce nonspecific arousal.

Thirty-two male Wistar rats (250–300 g) were used and a 23-gauge guide cannula was implanted 1 mm dorsal to the right or left lateral ventricle of each rat (coordinates for the surgery using the Pellegrino and Cushman atlas[8]: 0.6 mm posterior to bregma, 2.0 mm lateral of the midline suture, 3.2 mm ventral of the dorsal surface of the skull). Rats were then returned to their home cages where they had free access to food and water and were allowed 1 week to recover from surgery. On the eighth day after surgery (day 1), rats were started on a food deprivation schedule consisting of depriving the rats of food for 23 h and then placing them in individual wire testing chambers (20 × 25 × 36 cm) where they had access to wet mash [ratio of water/food 7:5 (v/v)] for 30 min. Food intake during this period was determined by calculating the difference between pre- and post-test food weight (including spillage). Rats were then returned to their home cages and allowed a further 30 min access to their regular laboratory diet after which the food was removed, but water was still available throughout the 23 h of food deprivation. This procedure was repeated for 5 days; by day 5, rats had stabilized their food intake during the 30-min test session (± 10% of average of the last 2 days). On day 6, all rats were pretreated 30 min before the feeding test session with one of four doses of rhGRF (0.0, 0.2, 2.0 or 20.0 pmol) administered i.c.v. All injections were made in a 2-μl volume of 0.01% ascorbic acid with a 30-gauge injector using gravitational force. Rats were maintained on the deprivation schedule following the day 6 test session and again tested for food intake the following day. In a second experiment, 26 different rats were tested with hpGRF(1–40) for food intake using the same method.

Both rhGRF and hpGRF(1–40) had a stimulatory effect on food intake. Figure 1 shows that although there was little change in the amount of food intake in rats treated with vehicle alone, there was an increase in intake for hpGRF(1–40)- and rhGRF-treated rats. A one-way analysis of variance revealed that this effect is statistically significant for both the hpGRF(1–40)-treated rats ($F(3, 22) = 4.398$, $P = 0.014$) and the rhGRF-treated rats ($F(3, 28) = 3.159$, $P = 0.039$). (All individual group comparisons were carried out using the Duncan multiple range *a posteriori* test.) Individual group comparisons with vehicle-treated rats revealed significant increases in food intake at 0.2, 2.0 and 20.0 pmol for both the hpGRF(1–40)-treated rats ($P < 0.05$) and the rhGRF-treated rats ($P < 0.05$). The mean food intake (±s.e.m.) on control days was 21.3 ± 2.1 g for rhGRF-treated rats and 28.5 ± 2.2 g for hpGRF(1–40)-treated rats. Both hpGRF(1–40)- and rhGRF-treated rats returned to baseline levels of food intake on the day after GRF tests: $F(3, 22) = 0.387$, not significant (NS) and $F(3, 28) = 0.720$, NS, respectively.

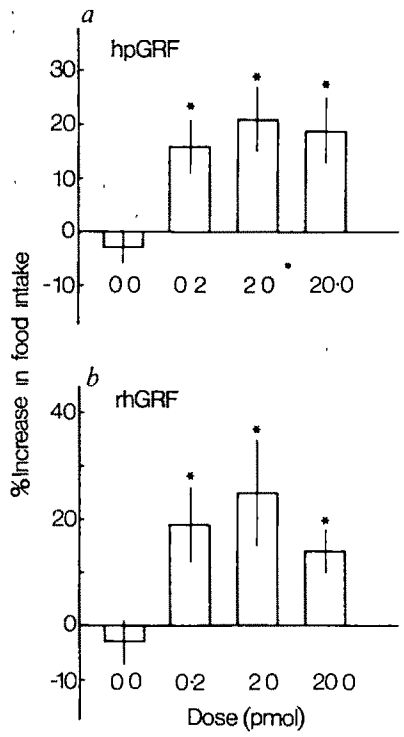

Fig. 1 The mean per cent increase in food intake after i.c.v. injections of *a*, hpGRF(1–40) ($n = 7$ for vehicle and 2.0-pmol groups, $n = 6$ for 0.2- and 20.0-pmol groups) and *b*, rhGRF ($n = 8$ for each group). 0.2, 2.0 and 20.0 pmol correspond to 1.0, 10.0 and 100.0 ng, respectively. Rats were assigned to their respective drug condition on the basis of their food intake on the previous 2 days such that the mean food intake before GRF treatment was approximately the same for all four drug treatment groups. Error bars represent the s.e.m. * Significantly different from vehicle-treated group, $P < 0.05$, Duncan multiple range *a posteriori* test.

In a third experiment using the same procedure, 24 rats were tested with GRF(3–40), a structurally related peptide completely unable to stimulate growth-hormone release[7], as a control for possible nonspecific effects of i.c.v. GRF injections. There were no effects of GRF(3–40) on food intake ($F(3, 20) = 1.007$, NS), suggesting that the facilitation in food intake observed in experiments 1 and 2 was probably not due to nonspecific effects of i.c.v. peptide administration.

Rats were maintained on the deprivation schedule following GRF(3–40) testing to investigate whether the increased food intake reflected an increased release of adenohypophyseal growth hormone or a direct result of peripheral responses that might also affect feeding. Thus, the same rats used for GRF(3–40) tests were re-divided into three groups and tested with rhGRF (0, 2.0 or 200.0 pmol) on day 8 by intraperitoneal (i.p.) injection in a 0.4-ml volume of 0.01% ascorbic acid. The peripheral injections of rhGRF had no significant effect on food intake ($F(2, 21) = 0.637$, NS). An additional six rats were subsequently tested with 0.2 pmol rhGRF injected i.p. Consistent

* Present address Scarborough Campus, University of Toronto, Division of Life Sciences, 1265 Military Trail, Scarborough, Ontario, Canada M1C 1A4

with the effects of 2 and 200 pmol, 0.2 pmol of rhGRF injected i.p. had no significant effect on food intake, $F(5) = 0.7$, NS. The fact that peripheral rhGRF did not influence food intake suggests that the GRF-induced facilitation of feeding is due neither to increased growth-hormone release nor to actions of GRF directly in the periphery.

To examine further the possibility that the present facilitatory effects of GRF on feeding are due to peripheral actions of GRF or increased growth-hormone release, the effects of peripheral injections of rat growth hormone were tested by the same procedure as experiments 1 and 2. On day 6, 24 rats were pretreated 30 min before the feeding session with one of four doses of rat growth hormone (0, 10, 50 and 250 μg per rat) administered i.p. These doses were chosen based on findings indicating that growth hormone values may normally reach 2 μg ml^{-1} in rat blood following endogenous GRF secretion (W.V., unpublished data). All injections were made in 0.4 ml of 0.03 M $NaHCO_3$ in 0.15 M NaCl and six rats were assigned to each growth hormone dose.

Our results demonstrated that rat growth hormone had no significant effect on food intake ($F(3, 20) = 0.313$, NS). The mean per cent control food intake (±s.e.m.) after 0-, 10-, 50- and 250-μg treatments was 104±10, 98±2, 100±7 and 95±3, respectively. The mean food intake (±s.e.m.) on control days was 25.8±1.1 g, suggesting that in the present conditions, the GRF-induced facilitation in food intake was probably not due to an increase in growth hormone release.

We tested the hypothesis that the increases in feeding observed following i.c.v. GRF treatment are the result of the general behavioural activating properties of GRF. Thus, 24 rats were tested for their locomotor response to one of the following doses of rhGRF: 0.0, 0.2, 2.0 or 20.0 pmol. rhGRF was administered i.c.v. as in experiment 1 and six rats were tested with each dose. Locomotor activity was measured as in previous studies[9]. We found no significant group effect of rhGRF on locomotor activity ($F(3, 20) = 0.399$, NS). Mean photocell beam interruptions (± s.e.m.) for the 0-, 0.2-, 2.0- and 20.0-pmol doses of rhGRF were 334±59, 438±87, 260±50 and 392±94, respectively. These results suggest that rhGRF, in the doses which produced a stimulation in food intake in the present study, do not produce general behavioural activation.

Our finding that low doses of centrally injected GRF can stimulate feeding is the first demonstration of a behavioural role for GRF. It is not yet clear whether the appetitive behaviour promoted by GRF is involved functionally in other peripheral actions initiated by central GRF secretion. Thus, the classic effects of growth hormone to promote growth of soft tissue in bone and cartilage[10], together with the central appetitive effect of GRF, suggest that central and peripheral factors may collectively underly growth processes in an integrated manner. Citing the actions of luteinizing hormone-releasing hormone, Moss and McCann[11] have proposed previously the concept of a central/peripheral integration of neuropeptide function. In the present study we add the actions of GRF as another possible case in point.

This research was supported by grant AM 26741 from the National Institute of Diabetes, Digestive Diseases and Kidneys. F.J.V. held a Natural Science and Engineering Research Council of Canada Postdoctoral Fellowship during this work.

Co-localization of $GABA_A$ receptors and benzodiazepine receptors in the brain shown by monoclonal antibodies

The most abundant inhibitory neurotransmitter in the central nervous system, γ-aminobutyric acid (GABA), exerts its main effects via a $GABA_A$ receptor that gates a chloride channel in the subsynaptic membrane[1]. These receptors can contain a modulatory unit, the benzodiazepine receptor, through which ligands of different chemical classes can increase or decrease $GABA_A$ receptor function[2,3]. We have now visualized a $GABA_A$ receptor in mammalian brain using monoclonal antibodies. The protein complex recognized by the antibodies contained high- and low-affinity binding sites for GABA as well as binding sites for benzodiazepines, indicative of a $GABA_A$ receptor functionally associated with benzodiazepine receptors. As the pattern of brain immunoreactivity corresponds to the autoradiographical distribution of benzodiazepine binding sites, most benzodiazepine receptors seem to be part of $GABA_A$ receptors. Two constituent proteins were identified immunologically. Because the monoclonal antibodies cross-react with human brain, they provide a means for elucidating those CNS disorders which may be linked to a dysfunction of a $GABA_A$ receptor.

Monoclonal antibodies were raised in mice immunized with a highly purified $GABA_A$ receptor/benzodiazepine receptor fraction from bovine cerebral cortex[4], a preparation characterized by: (1) the presence of binding sites for benzodiazepines as tested by ^{3}H-flunitrazepam (^{3}H-FNZ) binding; (2) high-affinity binding sites for GABA, assayed by ^{3}H-muscimol binding; and (3) low-affinity binding sites for GABA, monitored by the allosteric enhancement of benzodiazepine receptor affinity in micromolar concentrations of GABA[4]. The ligand specificity of these binding sites corresponds to that of the $GABA_A$ receptor/benzodiazepine receptor complex (receptor complex) in synaptic membranes[5]. The presence of low-affinity GABA binding sites coupled to benzodiazepine receptors is of interest as, electrophysiologically, the receptor complex is activated by micromolar concentrations of GABA[6-10]. We obtained a total of 22 monoclonal antibodies, with which 4 different epitopes of the $GABA_A$ receptor complex could be distinguished. We describe here two antibodies (bd-17 and bd-24) representative of the interaction with two of the receptor epitopes.

Antibodies recognizing the receptor complex would be expected to immunoprecipitate with a compound having the binding characteristics of the purified receptor. To test this premise, a bovine receptor complex fraction[4] was incubated with the antibody bd-17 or bd-24, followed by precipitation with goat/anti-mouse immunosorbent. As neither antibody inhibits the binding of ^{3}H-FNZ or ^{3}H-muscimol, the resuspended immunosorbent beads were tested in radioligand binding assays (Fig. 1). In controls without bd-17 or bd-24, no binding of ^{3}H-FNZ or ^{3}H-muscimol was found. When increasing concentrations of either bd-17 or bd-24 were added, however, increasing amounts of the binding sites for ^{3}H-FNZ and ^{3}H-muscimol were recovered, ≤90–95% of the total activity (Fig. 1). Binding of the benzodiazepine ^{3}H-diazepam (5 nM, 90 min, 4 °C) to the pellets was increased by 50±5% when tested in the presence of 10 μM GABA, indicating the presence of low-affinity GABA sites. The ligand specificity of these sites corresponds to that of membrane-bound $GABA_A$ receptors as benzodiazepine receptor binding was also enhanced by muscimol (1 μM), 3-aminopropanesulphonic acid and tetrahydroisoxazolopyridinol (THIP, 10 μM), but not by the $GABA_B$ receptor agonist

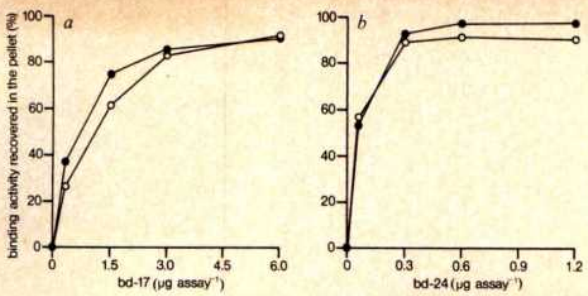

Fig. 1 Immunoprecipitation of binding sites for benzodiazepines and GABA with two monoclonal antibodies (*a*, bd-17; *b*, bd-24), recognizing different receptor epitopes. Filled and open circles represent specifically bound ^{3}H-FNZ and ^{3}H-muscimol, respectively

Methods. A partially purified $GABA_A$ receptor/benzodiazepine receptor preparation from bovine cerebral cortex (100 μl, ~30 μg ml^{-1}; ref. 4) was incubated for 2 h at 4 °C with 200 μl of bd-17 or bd-24 (previously purified by affinity chromatography on a sheep/anti-mouse antibody column), respectively. 200 μl immunosorbent (goat anti-mouse immunoglobulin G-agarose, Sigma A-6531, in phosphate-buffered saline (PBS), 0·2% Triton X-100 at a v/v ratio of 1:1) were added and the incubation continued for another 2½ h in the presence of 1% bovine serum albumin (BSA). After centrifugation, the pellet was washed once in 1 ml cold PBS, 0.2% Triton X-100, 1% BSA. The first supernatant and the final pellet were subjected to separate radioligand binding assays with ^{3}H-FNZ (10 nM, 60 min) and ^{3}H-muscimol (100 nM, 30 min). The radioligand binding assay for the supernatant was as described previously[21]. Radioligand binding to the pellet was performed in an Eppendorf tube on a turning wheel at 4 °C in 1 ml (final volume) of assay buffer (50 mM Tris/citrate *p*H 7.1 + 0.2% Triton X-100) containing the radioligand. After a short centrifugation, the resuspended pellet and rinse fluid of the tube were transferred onto a glass fibre filter and washed with 2 × 5 ml cold buffer. The radioactivity retained on the filter was measured using an external standard procedure. For each ^{3}H-FNZ and ^{3}H-muscimol binding experiment, nonspecific binding was determined in a parallel assay in the presence of 3 μM diazepam or 1 mM GABA, respectively. In controls which contained either no or an irrelevant antibody, only 7% of the binding activity was recovered in the pellet. This nonspecific precipitation was subtracted from all values. The results are expressed as % of total activity (100% = 100,000 d.p.m. ^{3}H-FNZ and 44,000 d.p.m. ^{3}H-muscimol, respectively): mean values of two experiments which differed <10% are given. Based on antibody concentration, the antigen-binding efficiency of bd-24 was about 10-fold higher than that of bd-17.

baclofen (100 μM), Thus, the immunoprecipitated material contained binding sites for benzodiazepines as well as low- and high-affinity binding sites for GABA, indicating that the antibody recognized the receptor complex. The same results were obtained with a purified receptor preparation from postmortem human cerebral cortex.

The presence of benzodiazepine receptors in the immunoprecipitated pellet was confirmed further by identifying the receptor protein with a covalently bound radioligand. When a purified bovine receptor sample was photoaffinity labelled with ^{3}H-FNZ (10 nM, 5 min ultraviolet; ref. 11) and immunoprecipitated subsequently with saturating amounts of either bd-17 or bd-24, 90% of the radioactivity incorporated into the protein was recovered in the pellet.

Benzodiazepine receptors in rat brain membranes consist of subunits of relative molecular mass (M_r) 50,000 and 55,000 (refs 11, 12). Similarly, a highly purified receptor complex from bovine brain contains two subunits of M_r 50,000–53,000 and 55,000–57,000, respectively[4,13–15]. We therefore expected these proteins to be recognized by the antibodies bd-17 and bd-24 in immunoblot experiments. In receptor preparations from postmortem human or bovine cerebral cortex, bd-24 labelled specifically a protein of M_r 50,000 and bd-17 a protein of M_r 55,000 (Fig. 2). Thus, each antibody apparently interacted with only one of the two putative constituent proteins of the receptor complex (Fig. 2). Both antibodies, however, were able to

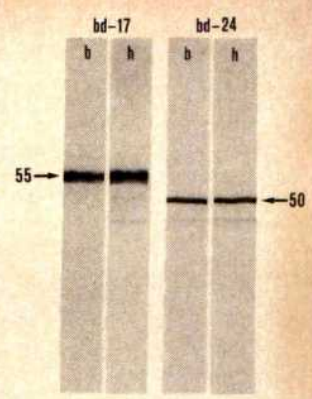

Fig. 2 Immunoblot of a bovine (b) and human (h) receptor complex preparation, showing the specificity of bd-17 and bd-24 for proteins of M_r 55,000 and 50,000, respectively. **Methods.** Partially purified receptor complex preparations from bovine or human cerebral cortex[4] were subjected to SDS-polyacrylamide gel electrophoresis. The resolved polypeptides were electroblotted onto a nitrocellulose membrane (HAWP, 0.45 μm pore size, Millipore) at 1 A for 90 min at room temperature in 25 mM Tris, 192 mM glycine and 20% (v/v) methanol, *p*H 8.3, according to Towbin *et al.*[22]. Unreacted sites on the nitrocellulose were blocked by three 10-min washes in 0.05% Tween-20 in PBS (PBS-Tween), according to De Blas and Cherwinski[23]. Strips of nitrocellulose were then incubated in bd-17 or bd-24 hybridoma supernatants, containing 0.05% Tween-20, at room temperature overnight under rocking. After three 10-min washes with PBS-Tween, the strips were incubated with ^{125}I-labelled sheep anti-mouse immunoglobulin (0.5–1.0 × 10^6 c.p.m. ml^{-1}; 30–60 ng ml^{-1}) in PBS-Tween, for 3 h at room temperature under rocking. Affinity purification and iodination of sheep anti-mouse immunoglobulins has been described previously[24]. Membrane strips were then washed 4× for 20 min in PBS-Tween and once in H_2O, dried and exposed to Kodak X-Omat AR film, using an intensifying screen (DuPont). M_r values of 50,000 and 55,000 are indicated by 50 and 55 respectively. The immunoreactive minor bands were presumably degradation products. All postmortem human brain was obtained through the Institutes of Pathology, Kantonsspital, Liestal and Basel (Switzerland).

immunoprecipitate the entire receptor population (Fig. 1), which suggests that the receptor complex has a mixed subunit composition. Furthermore, the immunoblot pattern (Fig. 2) excludes a simple proteolytic precursor–product relationship for the two proteins. No immunoreactivity was discovered in immunoblots using peripheral organs; when crude solubilizates of rat and bovine liver, heart and kidney were compared with crude solubilizates of brain containing a similar amount of protein, only the brain samples were immunoreactive with a pattern similar to that of the purified receptor.

As bd-24 and bd-17 seemed to immunoreact with a $GABA_A$ receptor complex, we attempted to localize it immunohistochemically. An identical pattern of immunological staining was obtained with bd-17 and bd-24 in bovine or human brain sections, whereas in the rat only bd-17 was immunoreactive. (The lack of immunoreactivity of bd-24 in the rat was confirmed by immunoblotting and immunoprecipitation using a purified receptor preparation from rat brain.)

Assuming that the observed immunoreactivity in grey matter represented a $GABA_A$ receptor associated with a benzodiazepine receptor, we expected the staining pattern to be similar to that of benzodiazepine receptors visualized autoradiographically[16,17] by radioligand binding. Indeed, when semi-adjacent sections were incubated with the benzodiazepine receptor ligand ^{3}H-Ro 15-1788, the regional distribution and intensity of binding were strikingly similar to that of the immune reaction (Fig. 3), indicating that most benzodiazepine receptors are part of $GABA_A$ receptors. This was shown in rat brain, spinal cord and retina as well as in bovine and postmortem human brain (Fig. 3). Areas which lacked benzodiazepine receptor sites also lacked immunoreactivity, for example, brain white matter, pineal gland and pituitary.

In the granular layer of the rat cerebellum and the ventrolateral thalamus (Fig. 3*a*), the intensity of the immune reaction was higher than expected from the density of benzodiazepine binding sites (Fig. 3*b*), corresponding more accurately to the density of high-affinity GABA binding sites visualized autoradiographically with ^{3}H-muscimol (Fig. 3*c*). Thus, in these two regions the receptor complex may occur in a conformational

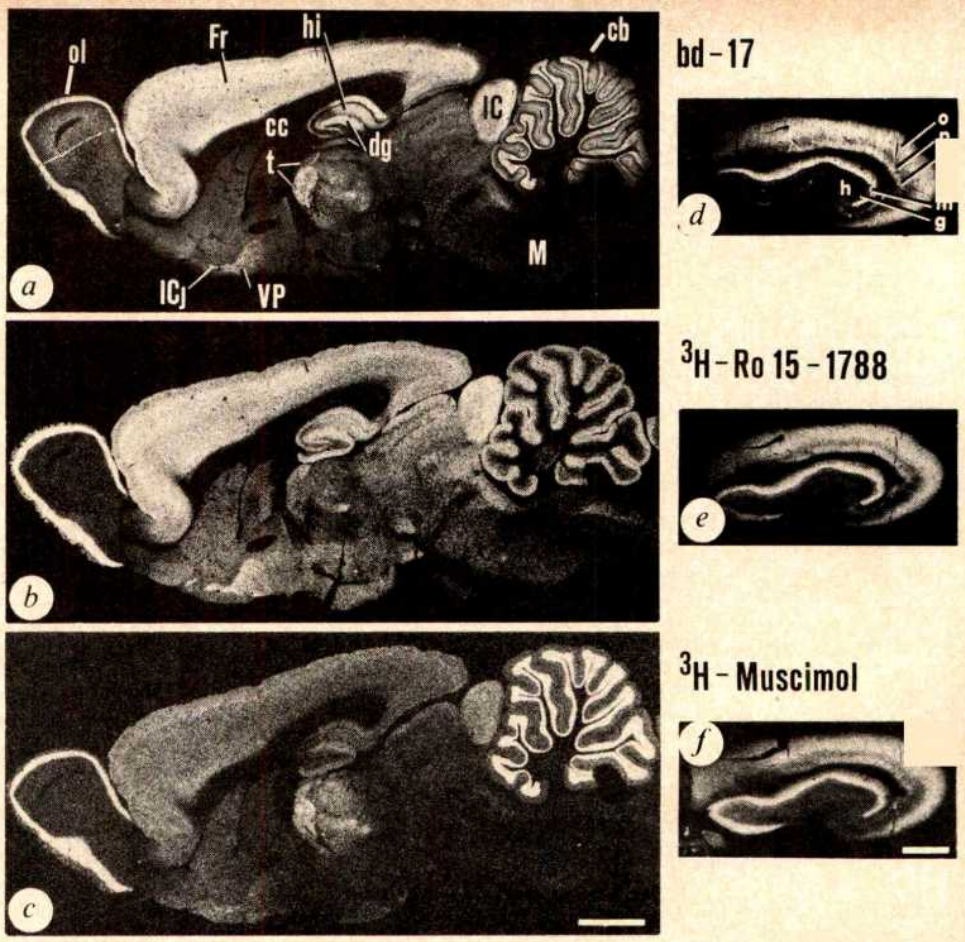

Fig. 3 Immunohistochemical localization of antigenic sites in rat brain (*a*, parasagittal section) and in postmortem human hippocampus (*d*, coronal section) using bd-17: comparison with the autoradiographic localization of benzodiazepine receptor sites (*b*, *e*; ^{3}H-Ro 15-1788 binding) and high-affinity GABA binding sites (*c*, *f*; ^{3}H-muscimol binding). In these negative images, white areas correspond to high densities of antigenic sites and radioligand binding sites.

Methods. *a*, *d*, For the immune staining the tissue was fixed with 2% formaldehyde + 0.1% glutaraldehyde in PBS. 10-μm cryostat sections were incubated, according to the indirect peroxidase/anti-peroxidase (PAP) technique[25], in sequence with: normal swine serum, hybridoma supernatant bd-17 (5–10 μg ml^{-1}), swine anti-mouse antiserum, PAP complex and finally diaminobenzidine/H_2O_2. In adsorption controls where bd-17 was preincubated with purified receptor complex, a nonspecific immunoreaction was observed, unless the receptor material was removed subsequently from the sample by a benzodiazepine receptor affinity resin[4]. Benzodiazepine receptor sites and high-affinity GABA binding sites were radiolabelled *in vitro* with 1 nM ^{3}H-Ro 15-1788 (*b*, *e*) and 5 nM ^{3}H-muscimol (*c*, *f*) respectively as described previously[16,20]. In the presence of 1 μM clonazepam and 10 μM GABA, binding of the respective radioligands was virtually absent. Abbreviations: cb, cerebellum; cc, corpus callosum; Fr, frontal cerebral cortex; dg, dentate gyrus; g, stratum granulosum of the dentate gyrus; h, hilus; hi, hippocampus; ICj, islands of Calleja; IC, inferior colliculus; M, medulla; m, stratum moleculare of the dentate gyrus; o, stratum oriens of the hippocampus; ol, olfactory bulb; p, stratum pyramidale of the hippocampus; r, stratum radiatum of the hippocampus; t, thalamus; VP, ventral pallidum. Scale bars, 2 mm.

state in which high-affinity GABA sites predominate and benzodiazepine binding sites are occluded. Alternatively, these areas may contain $GABA_A$ receptors not linked to benzodiazepine receptors but associated with Cl^- channels. The presumptive Cl^- channel ligand ^{35}S-*tert*-butylbicyclophosphorothionate[18], tested autoradiographically in rat cerebellum[19], showed the same pattern of distribution and density as the immune reaction in that brain region. If bd-17 and bd-24 cross-react with a $GABA_A$ receptor not linked to a benzodiazepine receptor, a structural homology between two types of $GABA_A$ receptors is suggested. The immunohistochemical staining does not seem to result from a nonspecific immune reaction, as preincubation of either antibody with the purified receptor fraction reduced the intensity of the immune reaction in a concentration-dependent fashion in all parts of the brain. Furthermore, controls with antibody-free medium or with an irrelevant antibody lacked immunoreactivity.

As benzodiazepines are used widely to treat anxiety states, sleep disorders, epileptic convulsions and muscle spasms, dysfunctions of the receptor complex may be involved in the aetiology of some of these disorders. Previous attempts to localize the receptor complex were restricted to the autoradiographical enhancement of radioligand binding to benzodiazepine receptors in micromolar concentrations of GABA[20], a technique of limited value for studies of postmortem human brain, as such receptor sites can be occupied through previous treatment with benzodiazepines. Furthermore, unknown amounts of endogenous GABA remaining in the tissue section could interfere with the enhancement of benzodiazepine receptor binding. In contrast, the immune reaction of bd-17 and bd-24 with the purified receptor remained unaltered in the presence of either GABA (5 mM) or diazepam (20 μM), as tested in a solid-phase antibody assay. Thus, an immunohistochemical investigation of postmortem tissue material can be performed irrespective of the presence of benzodiazepines or GABA and the structure containing the functionally relevant low-affinity GABA site can be visualized unequivocally with monoclonal antibodies. Furthermore, the resolution of the immunohistochemical localization of the receptor complex described here is superior to that of benzodiazepine receptor autoradiography, as single immu- noreactive cells with their processes can be visualized (J.G.R., in preparation). Thus, bd-17 and bd-24 may elucidate possible pathological alterations of the $GABA_A$ receptor/benzodiazepine receptor complex in postmortem human brain.

We thank M. Bixel, R. Schubenel and M. Willmann for technical assistance.

* Present address: Department of Genetics, University of Leicester, Leicester LE1 7RH, UK.

The *Drosophila melanogaster* male produces a species-specific courtship song by wing vibration. The most conspicuous feature of the song is a series of pulses with a 30–40-ms interpulse interval (IPI)[1,2] which oscillate in wild-type males with a period of 50–60 s (ref. 3). This short-term biological rhythm in IPI is influenced by several gene mutations at the *period* (*per*) locus, which alter the normal 24-h free-running period of the circadian clock[4] and have corresponding effects on the song cycle[3]. The present study reveals that, under restrictive conditions, temperature-sensitive mutations which affect neuronal membrane excitability seem to stop the biological clock underlying the fruitfly's song rhythm.

We have taken advantage of two temperature-sensitive mutations: nap^{ts} (no-action-potential temperature-sensitive) and $para^{ts1}$ (paralytic temperature-sensitive). Flies carrying these mutations are immobilized rapidly at temperatures >35 °C and 29 °C, respectively[5,6], but this paralysis is reversible, both mutants recovering within seconds when returned to 25 °C. At the higher restrictive temperatures, both mutants fail to generate action potentials[7]. These defects in nerve conduction may be caused by abnormalities associated with regenerative sodium channels. Our experimental design allowed individual nap^{ts} and $para^{ts1}$ males to begin courtship singing to normal females at 25 °C, then heat pulses were applied for 30 s to 'switch off' the male's nervous system. On recovery at 25 °C each male was permitted to continue his courtship. Pre- and post-treatment songs were then analysed to determine whether any phase shifts in the song cycle had occurred.

To control for the effects of the 30-s paralysis induced by failure of nerve conduction in the mutants, normal and mutant males were incapacitated for the same period of 30 s with short 7-s pulses of low temperature or CO_2 (see Table 1 and Fig. 1 legend). These control tests almost certainly do not obliterate membrane excitability except perhaps for a brief period within the 7-s pulse (see, for example, refs 8–11). In the analogous

Table 1 Induced phase shifts of the courtship song rhythm in *Drosophila* males

Genotype	Treatment	*n*	Mean phase shift (s) ± s.e.m. (advances = +, delays = −)	Range (s)
Experimental				
Wild type	30-s heat pulse (42 °C)	5	+1.5 ± 1.8	−4.9 to +5.0
nap^{ts}	30-s heat pulse (42 °C)	7	−31.2 ± 1.8	−38.2 to −26.1
$nap^{ts}cn$	30-s heat pulse (37 °C)	8	−28.9 ± 2.5	−39.1 to −21.3
$para^{ts1}$	30-s heat pulse (37 °C)	8	−31.0 ± 3.1	−39.0 to −16.1
$nap^{ts}cn$	15-s heat pulse (37 °C)	6	−16.2 ± 3.2	−25.2 to −2.0
$para^{ts1}$	15-s heat pulse (37 °C)	7	−13.0 ± 2.8	−23.8 to −3.9
$nap^{ts}cn$	45-s heat pulse (37 °C)	5	−48.4 ± 4.6	−59.3 to −36.3
$para^{ts1}$	45-s heat pulse (37 °C)	4	−47.5 ± 2.8	−53.9 to −40.8
Controls				
Wild type	Removed from female only	6	+1.0 ± 2.6	−6.7 to +9.9
$nap^{ts}cn$	Removed from female only	6	+0.5 ± 2.5	−9.9 to +7.0
$para^{ts1}$	Removed from female only	5	+1.3 ± 3.2	−8.0 to +8.0
Wild type	7-s cold pulse (0 °C)	4	+0.2 ± 2.4	−4.0 to +5.0
nap^{ts}	7-s cold pulse (0 °C)	4	−4.0 ± 1.3	−7.0 to −0.7
Wild type	7-s CO_2 pulse	5	−2.3 ± 1.2	−4.7 to +5.7
nap^{ts}	7-s CO_2 pulse	5	−1.8 ± 2.2	−7.1 to +5.3

Two strains carrying the chromosome 2 mutation nap^{ts} were used: one of these had been maintained at the California Institute of Technology at 25 °C and these flies were quickly immobilized at 42 °C. A second line, carrying the eye colour mutation *cinnabar* (*cn*) had been maintained at 18 °C by Dr Barry Ganetzky at the University of Wisconsin. The sex-linked $para^{ts1}$ mutation has also been maintained at 18 °C in Wisconsin, and both $nap^{ts}cn$ and $para^{ts1}$ flies showed nearly instantaneous paralysis at 37 °C. The males were placed in a preheated glass tube at either 37 °C or 42 °C and maintained at this temperature for 15, 30 or 45 s, as indicated. nap^{ts} and $para^{ts1}$ males became immobilized within 1–2 s at these temperatures and remained motionless for the duration of the heat pulse. The mutants were then removed from the tubes and replaced in the mating chamber at 25 °C where they regained full mobility within 2–5 s. The wild-type males did not 'pass out' during similar high-temperature treatment. Females were then re-introduced to the males. In the no-treatment controls, the male was simply removed from the female for 60 s and then returned. In this test the total time for which the male was removed from the female (including 20–25-s handling time) was 80–85 s, which corresponds to approximately $1\frac{1}{2}$ cycles of the normal 55-s song rhythm. Thus, if this treatment arrested the clock, the song rhythm would be approximately half a cycle out of phase when the male resumed his courtship. In a further control test, the male was immobilized in a chilled glass tube at 0 °C. All flies were immediately disabled at this temperature and usually remained in torpor for 25–35 s if the cold pulse was maintained for no longer than 7 s. Any male remaining motionless for less than 25 or more than 35 s was discarded. In a final control treatment, the courting male was removed from the female and placed in a small mating cell, into which CO_2 was blown for 7 s. Only those males that were anaesthetized and remained motionless for between 25 and 35 s were subsequently returned to the female. After each treatment males were allowed to continue their courtship for 5–8 min. Flies that had not resumed courtship 5 min after the end of the pulse were eliminated from further analysis. Males which did not sing vigorously either before or after the treatment were similarly discarded. Between 10 and 15 males were observed initially in each experiment but many did not court at all, either before or after the treatment, or sang so weakly that further analysis was not warranted. A vigorous courtship was operationally defined as one in which an average of 25 individual IPIs could be measured per 10 s of courtship time. Phase shifts were computed as described in Fig. 1 legend. Of the 170 songs analysed above (85 pre- and 85 post-treatment songs), 113 were significantly rhythmic beyond the 1% level (see ref. 3), 51 were significantly rhythmic beyond the 5% level and 6 just missed significance at 5%. In addition, 14 males sang vigorously but were arrhythmic in either their pre- or post-treatment songs. *n*, The number of males in each experimental group whose courtship song was analysed. Males were tested once only.

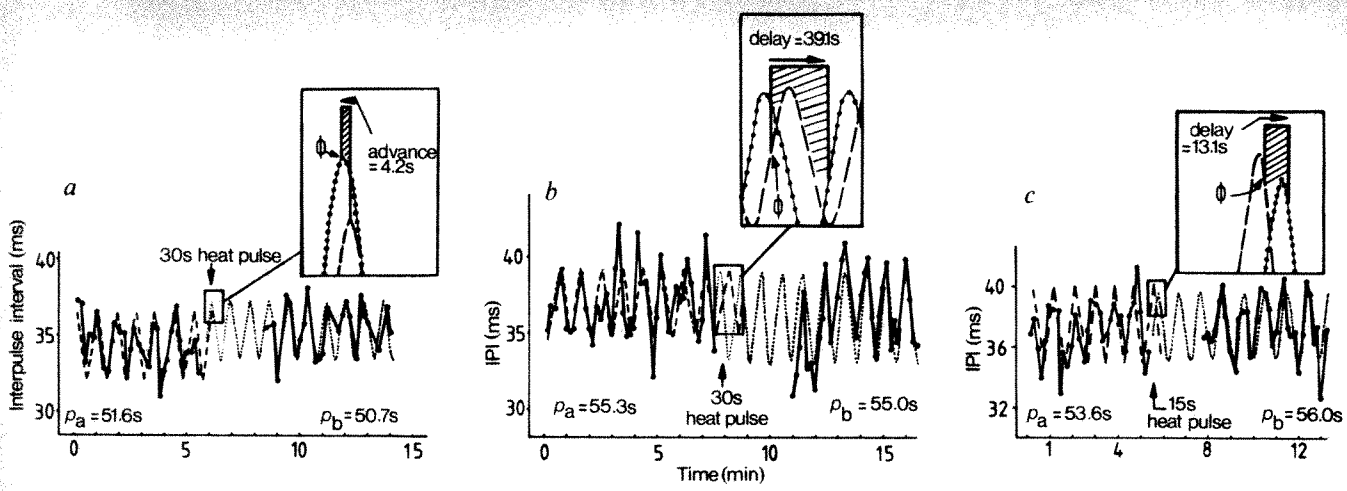

Fig. 1 Induced phase shifts of the song rhythms of *nap*^{ts}*cn* and wild-type *Drosophila* males. Each point represents the mean IPI per 10 s of courtship time (values of s.e.m. have been omitted for clarity, but 80% of all the s.e.m. values fall in the range 0.4–1.2 ms). Tape recordings of the courtship songs of 5-day-old males to 2-day-old virgin, attached-X chromosome females were made from a small mating cell using a ribbon microphone and were then input to an oscillograph to provide a visual record of the pulse trains[3]. IPIs were measured peak-to-peak with a ruler using minimum and maximum cut-off points of 15 and 65 ms, respectively. Song rhythms were obtained by calculating the mean IPI for successive 10-s time frames and placing these means into a computer together with approximate initial values for the parameters of a sine function. These parameters included the phase, period and amplitude of the rhythm, and the value around which the cycle oscillated. An iterative programme was run twice for each male's song, once to obtain the best-fitting sine wave for the pretreatment IPI means (dashed line) and then again for the post-treatment means (dotted line). The computer analysis was performed only after both sets of data (that is, pre- and post-treatment IPI means) had been calculated for each male. The goodness-of-fit of each set of data to its corresponding sine wave was examined using an *F*-test, yielding a measure of how 'sinusoidal' or 'rhythmic' the data were. Estimates of the various sine-wave parameters were used to calculate the phase shift between the pre- and post-treatment song rhythms. Because of the frequent small differences in the periods of the pre- and post-treatment songs (p_a and p_b, respectively), the phase shift between the two curves was calculated at the moment the treatment pulse was applied. ***a***, Song profile for a wild-type male subjected to a heat pulse (42 °C) for 30 s. The pretreatment song period, p_a, is 51.6 s: $p_b = 50.7$ s. The heat pulse was administered 370 s after the beginning of the courtship song, and when the pre-treatment song rhythm is extrapolated to this point, the phase at which the heat stimulus was applied, Φ, is 1.57 radians (this value is the peak of the cycle). Extrapolating the post-treatment song rhythm back to this point, the time coordinate which represents a phase of 1.57 radians for the post-treatment curve is 365.8 s. Thus the two peaks are 370 − 365.8 s, or +4.2 s, out of phase. This represents an advance of 4.2 s of the post-treatment song rhythm on that of the pretreatment. The shaded area in the inset represents this phase advance. ***b***, The song rhythm of a *nap*^{ts}*cn* male undergoing a paralysing 30-s heat pulse (37 °C) administered 470 s after the male initiated courtship singing. This time point corresponds to a phase of 5.95 radians on the pretreatment curve. The corresponding coordinates for Φ = 5.95 radians on the post-treatment curve fall at 454.1 s and then at 509.1 s on the following cycle, yielding phase shifts of either 470 − 454.1 = +15.9 s (advance), or 470 − 509.1 = −39.1 s (delay). We assumed initially that this phase shift was a delay (see text). The shaded area in the inset again represents the phase delay. ***c***, The song produced by a *nap*^{ts}*cn* male subjected to a 15-s paralysing heat pulse (37 °C), at 340 s. This time point represents Φ = 1.92 radians (again like ***a***, the heat pulse is initiated near the peak of the cycle) on the pretreatment curve. The corresponding time coordinate represented by this phase angle falls at 353.1 s on the post-treatment curve. The phase shift is therefore 340 − 353.1 = −13.1 s (delay).

mutant cases, action potentials are blocked for the duration of the paralysis. The no-treatment control represents a systematic test of our earlier observation that when a male resumes singing after previously interrupting courtship, the song cycles remain in-phase with those established earlier[3].

Table 1 summarizes the phase shifts induced by the various treatments and Fig. 1 illustrates some individual results. Mutant and wild-type males which received no treatment, except for a 60-s absence from the female, exhibited mean phase shifts of <2 s. Wild-type males subjected to 42° C pulses also showed small phase shifts. In the case of the mutants undergoing 30-s high-temperature pulses, we assumed initially that all phase shifts were delays; in these three groups the song rhythms were phase-delayed by ~30 s. In contrast, mutant and wild-type flies immobilized for between 25 and 35 s with 'cold' or CO_2 pulses showed small (<5-s) phase shifts. The small phase shifts in the controls can be classified clearly as advances or delays. The large (~30 s) phase shifts in the heat-pulsed mutants, however, are more difficult to categorize because 'delays' greater than half the song period can also be defined as advances. In Fig. 1*b*, which illustrates the song profile of a *nap*^{ts}*cn* male subjected to a 30-s heat pulse, the large 39.1-s delay could also be interpreted as an advance of 15.9 s. We therefore applied 15-s heat pulses to courting *nap*^{ts}*cn* and *para*^{ts1} males in the same conditions as before; we observed that all phase shifts could be unambiguously categorized as delays (that is, <180°), with the average phase shifts for the two mutant groups being ~15 s (see Table 1). Thus, we believe that the previous 30-s heat treatments similarly caused delays in the mutants. To confirm this interpretation of the data, we also applied 45-s heat pulses to courting *nap*^{ts}*cn* and *para*^{ts1} males. Our results supported the delay hypothesis in that large delays of ~45 s were observed in both groups (see Table 1). Thus, we conclude that 'shutting down' the nervous system in these mutants with heat pulses leads to a stoppage of the song clock proportional to the duration of the heat stimulus.

This is a novel result which does not have a parallel in the circadian literature. Circadian rhythms often reveal phase response characteristics when pulses of heat or cold are applied to a 24-h rhythm at various points in its cycle[12–14]. In the *nap*^{ts} and *para*^{ts} mutants, however, the song clock simply seems to 'stop' at restrictive temperatures and to start again when the fly is returned to the permissive temperature. Unfortunately, because of the small numbers of flies tested, it was difficult to determine whether there were any phase-response patterns in the songs of wild-type flies undergoing temperature pulses. Larger scale experiments using wider ranges of hot and cold pulses may be required if any phase-response curves are to be obtained for the song rhythm.

The *nap*^{ts} and *para*^{ts} mutations which we have used to block neuronal conductance act synergistically in that double mutants do not survive at any temperature[7], suggesting that the mutations share a common membrane excitability function. *nap*^{ts} seems to alter the density of sodium channels as deduced by tetrodotoxin (TTX) and saxitoxin binding studies[15–17], and wild-type flies given a sub-lethal dose of TTX, which blocks and therefore reduces the number of membrane-bound sodium channels, show temperature-sensitive paralysis similar to that of *nap*^{ts} flies[15]. Perhaps, therefore, the two mutations interrupt the

Drosophila song clock because of the direct[7] or indirect[15] effects of these genetic variants on the structure and function of sodium channels in neural membranes. Pharmacological manipulations of ionic fluxes change the phasing of a circadian oscillator localized in the *Aplysia* eye[18,19] but TTX does not phase-shift this neural rhythm[20]. In view of the latter result, it would be useful to examine whether the nap^{ts} and $para^{ts}$ mutations lead to a temperature-sensitive arrest of the circadian clock in flies. There is no reason to assume that every perturbation which affects the song clock will similarly affect the circadian clock, even though both rhythms share a common genetic mechanism via the effects of the *per* mutations[3]. For example, constant light disrupts the circadian clock, but not the song oscillation[3]. Therefore, the nap^{ts} and $para^{ts}$ mutations can be used to probe the differences as well as the similarities between short-cycling and circadian rhythms. The striking stoppage of the fly's song clock by block of neuronal conductance with the nap^{ts} or the $para^{ts}$ mutations indicates that this short-term rhythm is regulated by a neural oscillator. Genetic procedures[21] are available for localizing these presumptive neural 'foci', by constructing genetic mosaics which express nap^{ts} or $para^{ts}$ in their mutant tissues. Such studies may reveal whether these mutations lead to an interruption of the song cycle by affecting a small localized region within a ganglion or whether several sites (each perhaps containing a separate oscillator) must be simultaneously mutant in order for such arrests to be observed. In the latter case, communication may be blocked between oscillators which need to be coupled to regulate the phase of the rhythm; these foci may be the same or quite different from the sites of action of the *per* gene. Mosaic experiments on circadian behaviour have shown that the anatomical focus for the short-period per^s variant is localized in the fly's head[22]. Further work on the effects of the nap^{ts}, $para^{ts}$ and *per* mutations should help to elucidate the complex relationship between the mechanisms controlling short-term and circadian rhythms in *Drosophila*.

We thank John Ringo, Eve Marder and William Harris for their comments on the manuscript. The research was supported by SERC grant GRB 94595 to C.P.K. together with NATO and Advanced Fellowships, and USPHS grant GM-21473 to J.C.H. We also thank Seymour Benzer and Barry Ganetzky for providing the mutant stocks and Angela Reid for technical assistance.

Comparative chromosome mapping of a conserved homoeo box region in mouse and human

A. L. Joyner*, R. V. Lebo†, Y. W. Kan†, R. Tjian‡, D. R. Cox§ & G. R. Martin*

Specific genes are assumed to regulate pattern formation in the mammalian embryo, but as yet none has been identified unequivocally. It is possible that such genes in mammals may be identified by virtue of a conserved coding sequence, because many of the *Drosophila melanogaster* homoeotic and segmentation genes, which have crucial roles in the regulation of segmental pattern formation during embryonic development[1,2], contain a 180-base pair (bp) DNA sequence, the homoeo box[3-5], and that sequences homologous to the *Drosophila* homoeo box are also present in 6–10 copies in higher animals, including mammals[4-8]. Although the assumption that the homoeo box identifies genes responsible for pattern formation in mammals remains to be validated, it is a particularly attractive hypothesis given the strong conservation of homoeo boxes over vast evolutionary distances. Here we report the localization of a human homoeo box region[7], previously cloned and shown to contain two homoeo boxes within a sequence of 5-kilobases (kb), to the long arm of chromosome 17. We show that two single-copy homoeo box-flanking probes derived from this region strongly hybridize to single-copy restriction fragments in mouse genomic DNA and that these conserved homoeo box-flanking sequences map to mouse chromosome 11. This may be significant as several genes that map to chromosome 17 in human also map to chromosome 11 in the mouse, implying that a segment of mouse chromosome 11 is homologous to a region of human chromosome 17 (ref. 9). Taken together, these data suggest that the homoeo box region detected with our probes is highly conserved in human and mouse.

To determine the chromosomal location of the human homoeo box region, two single-copy probes were constructed. Figure 1 shows a restriction map of the cloned region of the human genome, containing two linked homoeo boxes[7] designated *Hu-1* and *Hu-2*, and illustrates the probes derived from it. One probe, H.1, is a 1.7 kb *Hin*dIII fragment containing the *Hu-1* homoeo box; the other probe, LF.2, is a 1.2-kb *Hin*dIII/*Eco*RI fragment containing sequences flanking the *Hu-2* homoeo box on the side opposite *Hu-1* or on the left side of *Hu-2* as the map is presented. Southern blot analysis has shown that the H.1 probe detects a single restriction enzyme fragment in human DNA when

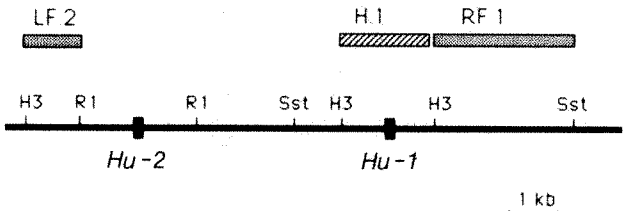

Fig. 1 Restriction map of the human homoeo box region studied. The probes used for the mapping studies are indicated. The restriction map was derived from two clones, λHu1 and λHu2, described elsewhere[7]. The horizontal line represents the human DNA sequence and the two small solid boxes represent homoeo boxes. The exact position of each of the homoeo boxes between the two restriction sites indicated has not been determined. The stippled and cross-hatched boxes above the restriction map represent the probes derived from this region. LF.2, or left flanking sequence to *Hu-2*, is a 1.2-kb *Eco*RI/*Hin*dIII fragment; H.1 is a 1.7-kb *Hin*dIII fragment containing the *Hu-1* homoeo box; and RF.1, or right flanking sequence to *Hu-1*, is a 2.4-kb *Hin*dIII-*Sst*I fragment. These fragments were subcloned into the vector SP65 and the recombinant plasmids (pLF.2, pH.1 and pRF.1) were used as probes. R1, *Eco*RI; H3, *Hin*dIII; Sst, *Sst*I.

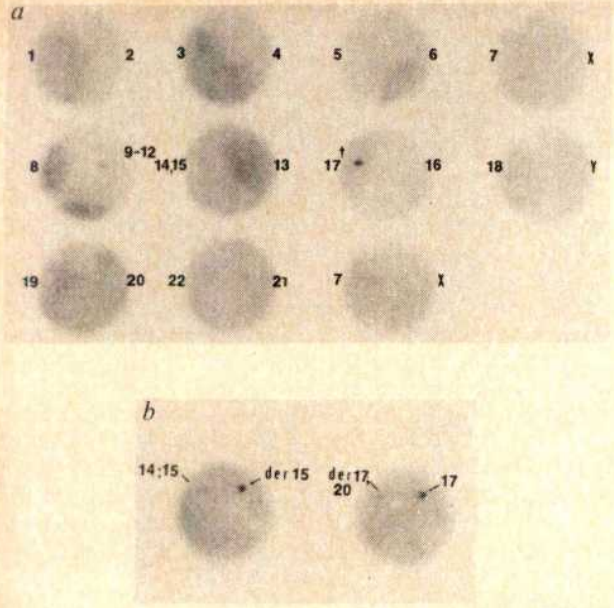

Fig. 2 Assignment of the human homoeo box region to the long arm of chromosome 17. *a*, Autoradiograph of a panel of spot blot filters containing flow-sorted human chromosomes hybridized to the LF.2 probe. *b*, Autoradiograph of spot blot filters containing flow-sorted chromosomes from a cell line containing a 15;17 reciprocal translocation hybridized to the LF.2 probe.
Methods. Chromosomes (30,000) of each type were either sorted directly onto spots on nitrocellulose filters, denatured and neutralized as previously described[10,11] or sorted directly into Leif buckets and identified by quinicrine-banding analysis. The filters were prehybridized overnight at 42 °C in 5×SSC, 5×Denhardt's solution, 250 μg ml^{-1} sonicated boiled salmon sperm DNA, 50 mM $NaPO_4$, *p*H 7, 0.1% SDS and 50% deionized formamide and hybridized for 48 h at 42 °C in the same solution containing nick-translated ^{32}P-labelled pLF.2 (3×10^6 c.p.m. ml^{-1}). After hybridization, the filters were washed three times for 5 min each at room temperature and twice at 50 °C for 30 min each in 2×SSC and 0.1% SDS, followed by one wash in 0.2×SSC for 30 min at 65 °C.

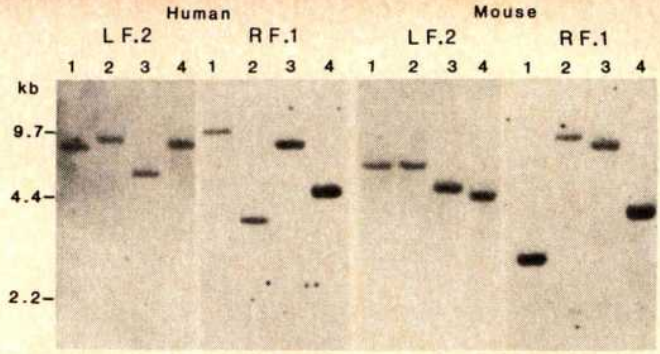

Fig. 3 Hybridization of the homoeo box flanking probes, LF.2 and RF.1, to human and mouse DNAs. The DNAs were restricted with the following enzymes: 1, *Eco*RI; 2, *Bam*HI; 3, *Hin*dIII; 4, *Sst*I.
Methods. Total cellular DNAs (10 μg) isolated from human and mouse tissues were cleaved with the restriction enzymes indicated. After gel electrophoresis and transfer to nitrocellulose, the baked filters were hybridized to pLF.2 and pRF.1 probes as described in Fig. 2 legend, except that the last wash in 0.2×SSC was at 50 °C and in some cases the filters were prehybridized and hybridized at 64 °C in 6.6×SSC, 10×Denhardt's, 0.1% SDS, 0.1% sodium pyrophosphate.

hybridized and washed in stringent conditions[7]. LF.2 also hybridizes to a single-copy sequence in human genomic DNA (see below).

To determine which human chromosome contains the homoeo box region, we used dual-laser chromosome sorting and spot-blot analyses[10,11]. Two panels of human chromosomes sorted directly onto nitrocellulose filters (spot blots) were hybridized with the H.1 and LF.2 probes and washed at high stringency (see Fig. 2 legend). Figure 2*a* shows an autoradiograph of a spot blot hybridized to LF.2. A specific signal is detected only in the fraction containing chromosome 17; the weak signal detected in the fraction containing a pool of chromosomes 9–12 is observed with most probes and is presumably nonspecific background which is more prominent in this dot owing to the presence of more DNA than in dots containing only one chromosome. As expected, hybridization of a similar panel of chromosomes to H.1 gives an identical result (data not shown).

In order to sub-localize the homoeo box-related sequences on chromosome 17, we sorted chromosomes from human fibroblasts heterozygous for a reciprocal translocation between the long arms of chromosomes 17 and 15 [46 XX, t(15; 17)(q22; q11)] (M. LeBeau and J. Rowley, personal communication). The normal chromosome 17 and the derivative 15 [der(15)], which contains the long arm of chromosome 17, are each sorted separately, whereas the derivative 17 [der(17)] which contains the short arm of chromosome 17, is sorted with chromosome 20 (not shown). Chromosomes 14 and 15 are sorted together and were spot-blotted as a negative control. Figure 2*b* shows an autoradiograph of the spot blot from this chromosome sort hybridized to the LF.2 probe. A specific signal is detected in the two fractions containing chromosome 17 and [der(15)]. Thus, these experiments localize the human homoeo box region shown in Fig. 1 to the long arm of chromosome 17.

Comparative gene mapping has demonstrated genetic homology between the long arm of human chromosome 17 and mouse chromosome 11, hence if the homoeo box region on human chromosome 17 is conserved in the mouse, it may map to mouse chromosome 11 (ref. 9). To test this hypothesis, we first demonstrated that DNA sequences homologous to the human chromosome 17 homoeo box region are present in mouse genomic DNA. In addition to the *Hu-2*-flanking probe LF.2, we constructed a 2.4-kb *Hu-1*-flanking probe (RF.1) containing sequences adjacent to *Hu-1* on the side opposite *Hu-2* or on the right side of *Hu-1* (see Fig. 1). The Southern blot experiments shown in Fig. 3 demonstrate that the LF.2 and RF.1 probes detect specific restriction fragments in human DNA cut with a variety of enzymes, indicating that each probe recognizes a different single-copy sequence in human DNA. The fragment sizes detected are those predicted from the restriction map of the human clones shown in Fig. 1. To demonstrate homology between these flanking probes and mouse DNA sequences, we hybridized a Southern blot of mouse genomic DNA restricted with a variety of enzymes to LF.2, and RF.1 under moderate stringency (see Fig. 3 legend). Figure 3 shows the results of such an experiment. The *Hu-1*- and *Hu-2*-flanking probes detect specific restriction enzyme fragments with each of the enzymes used.

To determine whether the single-copy mouse DNA sequences homologous to the probes LF.2 and RF.1 map to mouse chromosome 11, we used rat-mouse and Chinese hamster-mouse somatic cell hybrids. RTM9, a rat-mouse somatic cell hybrid clone, was formed by polyethylene glycol-mediated fusion of thymidine kinase-deficient Rat-2 cells with spleen cells from a mouse homozygous for an 11;13 robertsonian translocation chromosome, followed by selection in hypoxanthine-aminopterin-thymidine medium[12]. The murine 11;13 translocation chromosome is the only mouse chromosome in this hybrid clone and is present in over 90% of RTM9 metaphases analysed by standard trypsin-Giemsa banding techniques (data not shown). The mouse thymidine kinase gene is present on mouse chromosome 11. Thus, by growing RTM9 in medium containing 5-bromodeoxyuridine, we were able to isolate a subclone, RTM9-Bu, that lacks the mouse 11;13 chromosome but retains the same rat chromosome complement as the parental clone, as determined by karyotype analysis. We also tested a Chinese hamster-

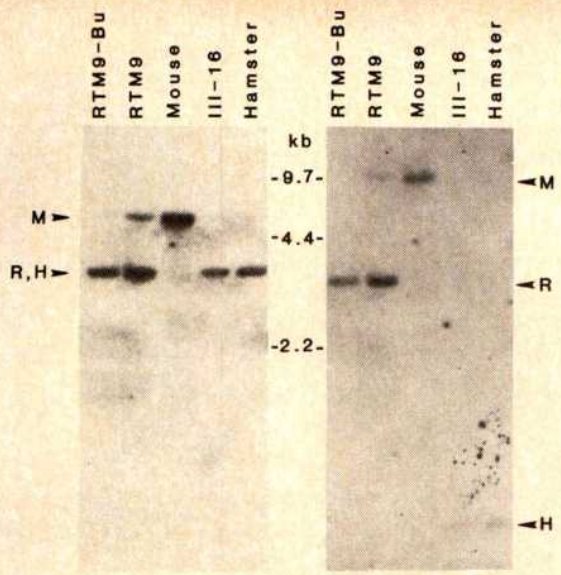

Fig. 4 Detection of mouse-specific LF.2 and RF.1 homologous sequences in DNA from the hybrid cell line RTM9, which contains mouse chromosomes 11 and 13, and demonstration of their absence from the cell hybrid III-16, which contains several mouse chromosomes including 13, but not 11. R, rat; M, mouse; H, hamster. **Methods.** Total cellular DNAs were isolated from normal mouse tissues, the rat–mouse somatic cell hybrid RTM9, the back-selected subclone RTM9-Bu, which contains no mouse chromosomes but retains the same complement of chromosomes as the parental clone, the Chinese hamster–mouse hybrid III-16, and the hamster cell line 380-6 that was used to construct III-16. These DNAs were cleaved with *Hin*dIII, Southern-blotted and hybridized to pLF.2 and pRF.1 probes as described in Fig. 3 legend.

mouse somatic cell hybrid, III-16 (ref. 12), containing mouse chromosome 13 as well as several other mouse chromosomes but lacking mouse chromosome 11. Genomic DNA was isolated from normal mouse tissues, RTM9, RTM9-Bu, III-16, and the Chinese hamster parental cell line 380-6 that was used to construct III-16. The murine DNA fragments detected by LF.2 and RF.1 were distinguished from the homologous hamster or rat DNA fragments on the basis of size after *Hin*dIII restriction enzyme digestion, followed by Southern transfer and hybridization at moderate stringency (see Fig. 3 legend). Figure 4 shows that the mouse-specific DNA fragments that hybridize with the LF.2 and RF.1 probes are present in RTM9 DNA, but not in DNA from RTM9-Bu or III-16. Results of a similar study using the H.1 probe were difficult to interpret because, in the moderate hybridization conditions used, this homoeo box-containing probe detects 6–8 DNA fragments in mouse, hamster and rat DNA. Taken together, these results demonstrate that the single-copy DNA sequences homologous to those in the human chromosome 17 homoeo box region are linked in the mouse, as they are in human, and map to chromosome 11.

The extent to which the homoeo box region is conserved between human and mouse will remain unknown until the homologous mouse *Hu-1*- and *Hu-2*-flanking sequences have been cloned and sequenced. The availability of the murine genomic clones should also make it possible to determine the number of homoeo boxes in this region. By analogy with human, we expect that this region of mouse chromosome 11 contains at least two homoeo boxes. This suggests that there may be clustering of homoeo boxes in mammals, as is the case in *Drosophila*. However, not all homoeo box-containing sequences map to mouse chromosome 11—at least one homoeo box sequence maps to mouse chromosome 6 (ref. 8), indicating that there is some dispersion of homoeo boxes in the mouse genome.

The fact that the human chromosome 17 homoeo box region is conserved in mouse suggests that this region is indeed part of a coding sequence in the mammalian genome. This conclusion is based on data from comparative sequence studies of gene families such as the globin genes, which demonstrate that coding regions are strongly conserved whereas introns and flanking sequences are generally not conserved[13]. Whether the genes found within this human/mouse homoeo box region have an important role in the control of mammalian development remains to be determined. In this context it may be relevant that two mutations that affect the number and form of the vertebrae have been mapped[14] to mouse chromosome 11: *vestigial-tail* is a viable recessive mutation, and *tail-short* is a dominant mutation which is viable in the heterozygous condition, but which causes embryonic death in the peri-implantation period when homozygous. It will be of interest to determine whether either of these mutations is allelic to the mouse cognate of the human homoeo box region that we have assigned to mouse chromosome 11.

The homoeo box is a 180-base pair (bp) DNA sequence conserved in *Drosophila* homoeotic genes, which regulate early development[1,2]. These DNA sequences are present in open reading frames and have been identified in specific gene transcripts in *Drosophila* and *Xenopus* embryos[3–5]; they possess structural features in common with genes encoding some DNA-binding proteins[6,7]. Homologous homoeo box sequences have been detected in species ranging from insects and annelids to vertebrates[2,5,8]. The high degree of sequence conservation (70–90%) among different species suggests a strong evolutionary relationship and implies a common role in embryonic development. To test this hypothesis, one approach we have used is to examine the patterns of genetic organization of homoeo box sequences in mouse and human for any similarities; the second approach is to localize the chromosomal map positions of homoeo box sequences in the two species. A similar genomic organization and chromosomal distribution of homoeo box sequences would argue for a conserved function and might shed light on their mechanism of action. Here, we describe experiments which show that two homoeo box loci map, respectively, to evolutionarily related regions on mouse chromosome 11 and human chromosome 17.

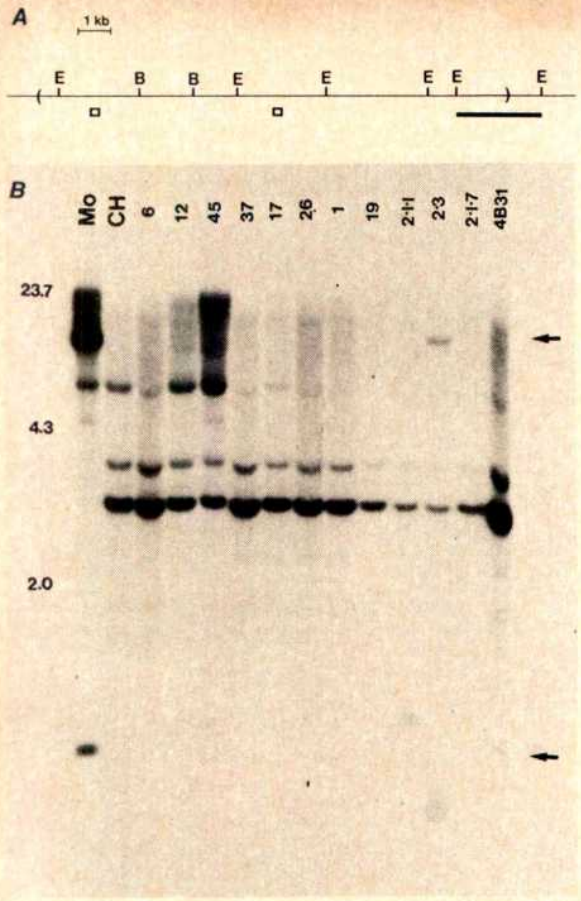

Fig. 1 *A*, Restriction map of the *Hox-2* recombinant phage insert. Boxes beneath the line indicate the two restriction fragments containing sequences homologous to the *Drosophila* homoeo box. The hybridization probe used for chromosomal mapping is underlined by the solid bar. The brackets indicate vector/insert cloning sites. B, *Bam*HI; E, *Eco*RI. *B*, Southern blot hybridization of mouse, hamster and mouse×hamster hybrid cell DNAs with the *Hox-2* DNA probe indicated in *A*. The *Hox-2* probe was nick-translated with ^{32}P-dCTP to a specific activity of 10^8 c.p.m. μg^{-1} and hybridized as reported previously[9]. The murine chromosome complement of the hybrid cell lines was determined by karyotyping and/or analysis of isozyme and DNA markers.

A recombinant phage clone containing murine DNA homologous to *Drosophila* homoeo box sequences was isolated from a mouse genomic library as reported previously[9]. Restriction site mapping of the murine DNA insert described here showed that this clone was not derived from the homoeo box locus (*Hox-1*) present on mouse chromosome 6 (ref. 9), hence we call this new region *Hox-2*. Southern blot hybridization of restriction enzyme-digested *Hox-2* DNA with a *Drosophila* homoeo box probe revealed two distinct regions of homoeo box sequence homology, 5 kilobases (kb) apart. This structural organization was similar to that reported for two linked homoeo boxes in the human genome (*Hu-1* and *Hu-2*)[8], and suggests that the *Hox-2* locus in the mouse and the region spanning the *Hu-1* and *Hu-2* probes in man may represent homologous genomic domains. As an initial step in the comparison of these homoeo box regions in mouse and human, we have mapped these loci to determine whether they are localized in evolutionarily related chromosomal regions.

To map the cloned mouse sequences, 20 mouse×hamster hybrid cell DNAs were probed with a 2.7-kb *Eco*RI fragment flanking the homoeo box regions of the *Hox-2* recombinant phage insert (Fig. 1*A*). The murine DNA contained in this fragment hybridizes with 0.9-kb and 10-kb *Hin*dIII fragments in a mouse genomic Southern blot. A strongly cross-hybridizing band of 3 kb is present in the hamster genome. In addition,

Table 1 Segregation of *Hox-2* in mouse-hamster hybrids (presence of chromosome/blot hybridization)

Mouse chromosome	Concordant +/+	Concordant −/−	Concordant Total	Discordant +/−	Discordant −/+	Discordant Total

Summary of the blot hybridization results for 21 mouse×hamster hybrid cell line DNAs probed with the *Hox-2* DNA fragment (see Fig. 1*A*). The presence or absence of mouse chromosome 11 is concordant with the presence or absence of the *Hox-2* diagnostic mouse bands.

other more weakly hybridizing bands are seen in both the mouse and hamster genomes (Fig. 1*B*). Scoring the hybrid cell lines for the *Hox-2* mouse-specific fragments assigns this genomic locus to mouse chromosome 11. Table 1 summarizes the data, showing no discordancies either for the presence or absence of chromosome 11 in the hybrids or for the presence or absence of the diagnostic murine restriction fragments.

The human homoeo box sequences, *Hu-1* and *Hu-2*, were regionally mapped by *in situ* hybridization to human metaphase chromosomes[10,11]. The chromosomes were identified by G-banding before hybridization. After hybridization and autoradiography, the distribution of silver grains over 73 previously photographed chromosome spreads was plotted on a histogram (Fig. 2*A*) in which a standard idiogram of the haploid human karyotype was divided into 238 units scaled to the average size of a silver grain (0.35 μm). Of 712 grains assigned to chromosomes, 140 (20%) were specifically localized to 17q11–q22, which represents 0.8% of the haploid genome length. Statistical evaluation (by Poisson distribution) of the number of grains per unit chromosome length confirmed a highly significant concentration of label within this region ($P \ll 0.001$). Figure 2*B* shows a representative chromosome spread hybridized with the *Hu-1* and *Hu-2* probes. Analysis of a further 24 labelled chromosomes 17 from 30 metaphase spreads (Fig. 2*C*) illustrates the localization of the *Hu-1* and *Hu-2* homoeo box probes to 17q11–q22.

Comparative mapping between mouse and human has revealed conservation of syntenic linkage associations for several chromosomes[12–14]. Here we present data indicating that two mouse and human homoeo box loci map to evolutionarily related chromosome regions in these species. The human *Hu-1* and *Hu-2* clones have been regionally localized to 17q11–q22; also present at this site are the pro-α1(I) collagen gene[15,16]; the thymidine kinase (TK) and galactokinase (GALK) genes, which have been shown to be tightly linked (within 1.2 centimorgans)[17–19]; a cluster of genes for growth-regulating hormones, including growth hormone and CSH[20,21]; and the cellular homologue of the *erb-A1* oncogene, which is believed to enhance the transforming potential of leukaemogenic cells[22,23]. The mouse *Hox-2* locus has been assigned to chromosome 11; the murine TK and GALK genes have previously been mapped 71 centimorgans from the centromere of this chromosome[24,25]. As

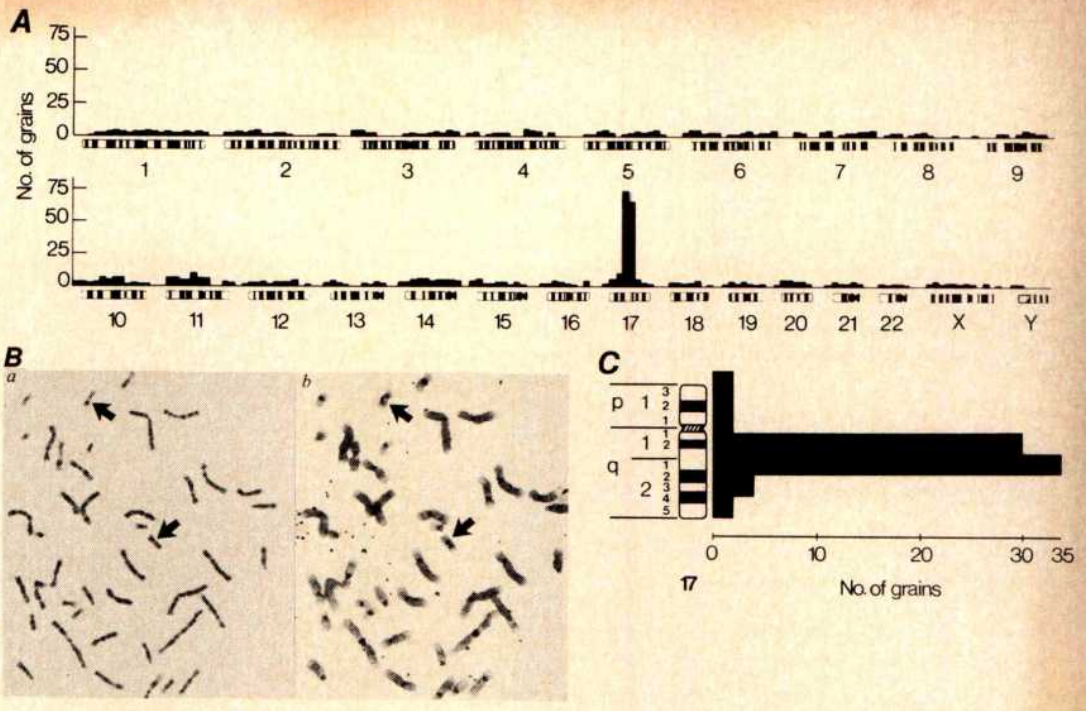

Fig. 2 Regional localization of the human *Hu-1* and *Hu-2* homoeo box sequences. *A*, Distribution of autoradiographic silver grains over 73 chromosome spreads after *in situ* hybridization with ^{125}I-labelled *Hu-1* and *Hu-2*. The data were plotted on a histogram representing the haploid human karyotype. If 712 grains appearing on chromosomes, 140 (20%) were localized within the region 17q11–q22. *B*, G-banded chromosome spread (JS cell line) before (*a*) and after (*b*) hybridization. The arrows indicate *Hu-1* and *Hu-2* signal on chromosome 17. *C*, Distribution of silver grains on labelled chromosomes 17 from 30 metaphase spreads, showing localization of the *Hu-1* and *Hu-2* homoeo box sequences to 17q11–q22.

Methods. Human metaphase chromosome spreads were prepared by standard techniques from cultures of karyotypically normal Epstein–Barr virus-transformed lymphoblastoid cell lines (JS, DB and PM). *Hu-1* and *Hu-2*, containing 1.7- and 2.1-kb human DNA inserts, respectively[8], were mixed 1:1 and nick-translated with ^{125}I-dCTP (2,000 Ci mmol^{-1}; Amersham) to a specific activity of 6.4×10^8 d.p.m. μg^{-1} (ref. 31). Unincorporated nucleoside triphosphates were removed by CF11 cellulose chromatography[32]. Chromosome preparations were hybridized with ^{125}I-labelled *Hu-1* and *Hu-2* probe mix (0.15 μg ml^{-1}) at 37 °C for 16 h and autoradiographed for 7–21 days as described previously[10,11].

linkage of the genes for TK and GALK has been conserved in both species, the mouse *Hox-2* locus probably maps close to these genes. These data also suggest that the *Hox-2* locus in the mouse is homologous to the genomic domain containing the human homoeo box regions *Hu-1* and *Hu-2*. It will be interesting to determine whether the murine *erb-1* gene which has been assigned to mouse chromosome 11, maps within this linkage group also.

Genetic mapping studies can suggest or eliminate possible allelism of the homoeo box loci with genomic loci known to affect mammalian development. In the mouse, a gene not ruled out by such comparison is *tail-short* which maps 65 centimorgans from the centromere of mouse chromosome 11 (ref. 26). Homozygotes for *tail-short* do not survive beyond day $5\frac{1}{2}$ of gestation; heterozygotes have skeletal abnormalities which include vertebral fusions, bilateral asymmetry of limb length, triphalangy and an additional pair of ribs. Fine-structure mapping of the *Hox-2* locus using restriction fragment length polymorphisms and recombinant inbred strains of mice could indicate a coincident map position and justify investigation at the molecular level of the relation between the *Hox-2* locus and the *tail-short* mutation. A similar rationale has been proposed to test for allelism between the *Hox-1* locus and hypodactyly, another mutation affecting morphogenesis, which both map to the same region on chromosome 6 (ref. 9). While the function of the mouse homoeo box loci remains speculative, the recent observation that they are transcriptionally active only at specific stages of mouse embryogenesis (C.P.H., Awgulewitsch and F.H.R., in preparation) indicates that their expression is subject to strict temporal regulation, as expected for a gene which in turn modulates morphogenetic patterns. Dysmorphic syndromes in humans include dyssegmental dysplasias[27] and anispondylic comptomicromelic dwarfism (dyssegmental dwarfism)[28,29], which are neonatally lethal genetic lesions characterized by vertebral segmentation defects. Recent evidence[30] suggests an association between dyssegmental dwarfism and defects in the metabolism of α1 collagen, the gene for which maps to the same region of chromosome 17 as the homoeo box loci reported here[15,16]. As these cases represent rare occurrences in the general population, there is insufficient genetic data to indicate involvement of homoeo box loci at present. To obtain a better understanding of the function of homoeo box regions during development, studies are under way to compare the temporal and spatial expression of homoeo box sequences during embryogenesis in mouse and man, by blot hybridization to mRNA purified from embryos obtained at progressive stages of gestation and by *in situ* hybridization to endogenous mRNAs in embryo tissue sections. If these genetic loci behave as predicted by analogy to the *Drosophila* homoeotic genes, such data will provide insights into the molecular events controlling mammalian development.

A *Drosophila* genomic sequence with homology to human epidermal growth factor receptor

Samuel C. Wadsworth, Walter S. Vincent III & Diana Bilodeau-Wentworth

Cell Biology Group, Worcester Foundation for Experimental Biology, Shrewsbury, Massachusetts 01545, USA

Vertebrate genomes contain an extensive family of genes possessing varying degrees of homology to the v-*src* oncogene. Most *src*-related proteins identified to date are intracellular and membrane-associated, although some are transmembrane proteins and function as receptors for peptide growth factors[1-6]. Three *Drosophila* gene sequences related to the v-*src* gene have been identified, each exhibiting a high degree of homology to one or more of the *src*-family members encoding an intracellular protein[7-9]. We have isolated a panel of cloned *Drosophila* sequences exhibiting weak v-*src* hybridization and were interested to determine whether any members of this group represented homologues of additional known *src*-family genes, especially those functioning as growth factor receptors. As we report here, four of these clones, representing overlapping portions of the same genomic segment, hybridized preferentially with the v-*erb-B* oncogene and were further characterized. The deduced amino-acid sequence from a portion of this *Drosophila* genomic segment is 77% homologous to the kinase domain of human epidermal growth factor (EGF) receptor, a substantially greater degree of homology than was observed with any other known *src*-family member. By hybridization with a human EGF receptor complementary DNA clone probe[10], we demonstrate that the same genomic segment showing homology with the kinase domain also contains sequences related to the extracellular domain of the EGF receptor gene.

By screening a *Drosophila* genomic library using hybridization with v-*src* sequences, two types of clones were isolated, exhibiting respectively strong and weak homology with v-*src*. Each of the clones in the former group represented one of the three major *Drosophila src*-related sequences characterized previously[7-9]. To exclude the possibility that the members of the group showing weak homology to v-*src* were repeat isolates of the previously characterized *Drosophila src*-related sequences, DNA from these clones was hybridized in stringent conditions with probes representing each of the three major *Drosophila src*-related genes; none of the clones reacted with any of these sequences. As the *src* gene family in vertebrates contains many divergent members, we wished to test whether the clones showing low homology to v-*src* contained other known vertebrate *src*-family sequences. The first *src*-family oncogene chosen for secondary screening of these clones was v-*erb-B*, which contains a portion of the avian EGF receptor gene[6]. DNA from each of the 11 clones in the low-homology group was tested by Southern blot[11] hybridization with the 0.56-kilobase (kb) *Bam*HI segment of v-*erb-B*[12]. This portion of the v-*erb-B* sequence encodes the kinase domain, the most highly conserved region of *src*-family genes. A variable-sized *Eco*RI segment and a 1-kb *Taq*I fragment from each of the clones Dsrc13, Dsrc16, Dsrc25 and Dsrc42 hybridized more strongly with the v-*erb-B* probe than did DNA from the other seven clones. The 1-kb *Taq*I fragment also hybridized weakly but reproducibly with the 0.54-kb *Bam*HI/*Eco*RI segment of v-*erb-B*, adjacent to and downstream from the 0.56-kb *Bam*HI fragment of v-*erb-B*[4] (Fig. 1).

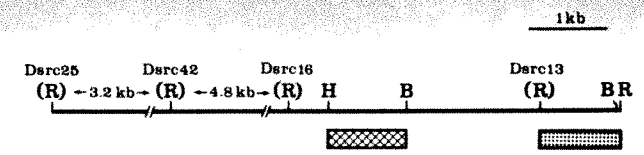

Fig. 1 Restriction endonuclease cleavage map of clones Dsrc13 and Dsrc16. R, *Eco*RI sites; B, *Bam*HI; H, *Hin*dIII. The v-*erb-B*-complementary *Eco*RI segments of Dsrc13 and Dsrc16 were subcloned into pUC8 for sequencing and restriction mapping. The *Eco*RI sites in parentheses are not genomic sites but are a result of the introduction of linkers during cloning. The dotted box below the map indicates the region that hybridized with v-*erb-B* *Bam*HI and *Bam*HI/*Eco*RI probes, while the cross-hatched box indicates the region that hybridized with the *Eco*RI/*Nae*I probe specific for the extracellular domain of the human EGF receptor. Hybridizations with the heterologous probes were conducted as follows. Southern blots were pre-hybridized for 3 h at 60 °C in 4×SET (1×SET is 0.15 M NaCl, 0.03 M Tris-HCl *p*H 8.0, 2 mM EDTA), 10×Denhardt's solution[18], 0.1% SDS and 0.1% sodium PP_i and for an additional hour in the same solution containing denatured calf thymus DNA (Sigma) at 50 μg ml^{-1}. After overnight hybridization in the latter solution in the presence of denatured ^{32}P-labelled probe, the filters were washed according to the following schedule: 1 h at 60 °C in the hybridization solution; three 45-min intervals at 60 °C in 3×SET, 0.1% SDS and 0.1% sodium PP_i; 45 min at 60 °C in 0.3×SET, 0.1% sodium PP_i, 0.1% SDS and a final wash in 4×SET at room temperature.

Because these clones were isolated by low-stringency hybridization, it was important to determine the nucleotide sequence of a portion of the *Drosophila* DNA so as to demonstrate significant structural homology with the vertebrate EGF receptor gene. The 1-kb *Eco*RI segment of Dsrc13 which hybridized with v-*erb-B* probes was therefore subcloned into plasmid pUC8 and further subcloned into phage M13 mp8. Figure 2 shows the nucleotide sequence and the deduced amino-acid sequence of a portion of the Dsrc13 clone. The *Drosophila* sequence begins at the left end of Dsrc13 (Fig. 1) and corresponds to the cDNA sequence of human EGF receptor[10] at positions 2,383–2,742. This region represents the first 60% of the v-*erb-B* *Bam*HI fragment used as hybridization probe to identify the *Drosophila* clones.

There are several points of note about the sequence data. First, overall there is 64% nucleotide sequence homology between the two sequences. The longest region of extensive homology, 70%, is from position 166 to the end of the sequence. As the sequence of the *Drosophila* clone further downstream exhibits less homology with the EGF receptor sequence (data not shown), it is apparent that the region shown was responsible for the observed hybridization with the v-*erb-B* *Bam*HI probe. Second, this region of the avian c-*erb-B* gene is interrupted by at least two introns totalling ~4,600 base pairs[13]. As the *Drosophila* DNA sequence and human cDNA sequences are co-linear, this region of the *Drosophila* gene lacks the two introns present in the avian gene. The structure of the analogous region of the human EGF receptor gene has not been documented. Third, at the amino-acid level, there is 62% homology between the *Drosophila* and human sequences. However, at position 166–360, the amino-acid sequence homology is 77%. It is perhaps noteworthy that the lysine residue at position 295 in the v-*src* protein, which is highly conserved in *src*-family proteins, is also conserved in the *Drosophila* sequence (encoded by nucleotides 37–39, Fig. 2). The analogous amino acid in cyclic AMP-dependent protein kinase is thought to be located in the nucleotide-binding site of the enzyme[14-16].

Because the kinase domain of *src*-family genes is highly conserved, it was important to demonstrate that the homology between the EGF receptor sequence and the Dsrc13 sequence

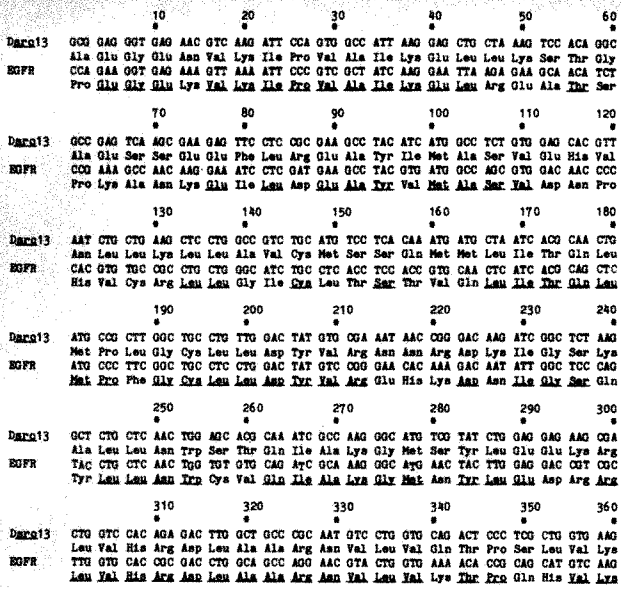

Fig. 2 Nucleotide sequence of a portion of the subcloned *Eco*RI segment from Dsrc13 and the deduced amino-acid sequence. Sequencing was performed by the chain-terminator method[19] using M13 mp8 templates generated by cleavage with *Eco*RI, *Msp*I or *Sau*3A. The sequences were aligned and translated using computer programs[20]. The sequence of the human EGF receptor was taken from ref. 10. Position 1 in the *Drosophila* sequence corresponds to nucleotide 2,383 in the human sequence. Underlined amino acids in the human sequence indicate amino acids conserved in the *Drosophila* sequence.

was significantly higher than that between other *src*-family genes. For this, we selected the region of the *Drosophila* sequence exhibiting the greatest homology with the EGF receptor sequence, nucleotides 166–360. Figure 3 compares the *Drosophila* amino-acid sequence with the sequences of other *src*-family genes. The finding that the homology between the *Drosophila* sequence and the EGF receptor exceeds the next highest comparison by 25% indicates that the Dsrc13 sequence is significantly more closely related to the kinase domain of the EGF receptor than to other known *src*-family genes. Comparisons of the Dsrc13 sequence with v-*raf*, v-*mos* and v-*fgr* are not shown, as the homologies were even lower than those shown in Fig. 3.

The relationship of the cloned *Drosophila* sequences to genomic sequences was defined by a series of Southern blot hybridizations. As noted above, *Eco*RI segments of varying sizes were detected in these clones by v-*erb-B* hybridization, the largest being >12 kb in clone Dsrc25. This suggested that the *Eco*RI site terminating the left-hand end of clone Dsrc13 (as well as Dsrc16 and Dsrc42) was not a genomic site and therefore Dsrc13 and v-*erb-B* probes should hybridize to a genomic *Eco*RI fragment of 12 kb or larger. In addition, as the v-*erb-B* probe detected a *Taq*I fragment common to each of the clones, a similar *Taq*I fragment should be present in genomic DNA. When *Drosophila* genomic DNA restricted with either *Eco*RI or *Taq*I was hybridized in low-stringency conditions with the v-*erb-B Bam*HI probe (Fig. 4*a*), two *Eco*RI segments of 22 and 13.5 kb and two *Taq*I segments of 1 and 0.5 kb were detected. The two *Eco*RI segments hybridized with similar efficiency, while the smaller *Taq*I segment hybridized weakly and is not visible as reproduced here. The 1-kb *Taq*I fragment was equivalent in size to the *Taq*I fragment from each of the Dsrc13, 16, 25 and 42 clones which was also detected by v-*erb-B* hybridization. The same genomic blot was subsequently hybridized with a probe from the subcloned *Eco*RI segment of Dsrc13 (Fig. 1) in high-stringency (Fig. 4*b*) and low-stringency conditions (Fig. 4*c*). In high-stringency hybridization conditions, the Dsrc13 probe detected only the 22-kb *Eco*RI segment and the 1-kb *Taq*I segment. Thus, the larger of the two genomic *Eco*RI segments contains the sequences represented by the overlapping set of clones that we have identified by v-*erb-B* hybridization. In low-stringency hybridization conditions, the Dsrc13 probe still hybridized primarily with the larger of the *Eco*RI and *Taq*I bands, although weak hybridization to the v-*erb-B*-complementary 13.5-kb *Eco*RI segment and at least one additional *Eco*RI segment was observed. These results suggest that there is a single-copy genomic segment represented by the set of overlapping clones Dsrc13, 16, 42 and 25 identified by hybridization with v-*src* and v-*erb-B* probes. The presence of additional genomic sequences showing homology to v-*erb-B* is suggested by the smaller *Eco*RI segments that hybridized with the v-*erb-B* and Dsrc13 probes in less stringent conditions. We believe that some of the additional genomic sequences detected by v-*erb-B* hybridization represent *Drosophila src*-family sequences related to the kinase domain of the v-*erb-B* oncogene. Confirmation of this hypothesis awaits the isolation of the remainder of the v-*erb-B*-complementary genomic segments.

Although the above results documented a degree of homology between Dsrc13 and the cytoplasmic domain of the human EGF receptor, we could not conclude that the *Drosophila* sequences represented a true homologue of the vertebrate gene. In addition to the kinase domain, the EGF receptor contains a short transmembrane domain and a large extracellular domain that is responsible for EGF binding[10], and it was important to determine whether other portions of the vertebrate gene were represented on one or more of our *Drosophila* clones. An *Eco*RI/*Nae*I fragment from the human EGF receptor cDNA clone was isolated as a hybridization probe specific for the extracellular domain of EGF receptor; this fragment starts at position 293 from the extreme 5′ end of the amino-acid-coding region and stops short of the transmembrane domain by 100 nucleotides[10]. Hybridization of clones Dsrc16, 42 and 25 with the *Eco*RI/*Nae*I probe revealed the same *Eco*RI segments that hybridized with the v-*erb-B Bam*HI probe (data not shown, see Fig. 1). These *Eco*RI segments vary in size due to the introduction of *Eco*RI linker sites during construction of the library[17]. DNA from clone Dsrc13 did not hybridize with the *Eco*RI/*Nae*I probe, a not unexpected finding considering the sequence and arrangement of this clone. To characterize further the homology of the *Eco*RI/*Nae*I probe to *Drosophila* sequences, the pattern of hybridization to cloned and genomic sequences was determined. In the cloned DNA, *Eco*RI/*Nae*I probe hybridization was limited to a 1-kb *Hin*dIII/*Bam*HI segment (Fig. 4*d*). The pattern of *Eco*RI/*Nae*I probe hybridization to genomic DNA

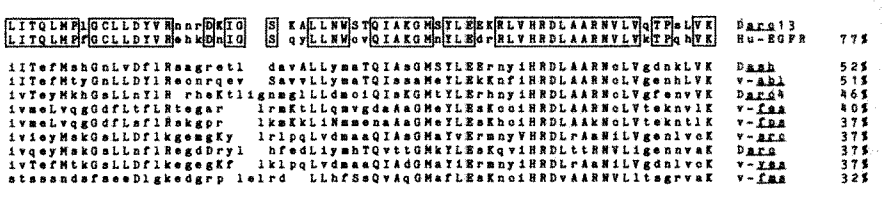

Fig. 3 Alignments of deduced amino-acid sequences of Dsrc13, EGF receptor and other *src*-family members. The sequence of Dsrc13 for amino acids 56–120 was aligned with the analogous region of various *src*-related proteins. The gaps in some of the sequences were introduced manually to achieve maximal alignment of the most highly conserved regions. Only the matches between Dsrc13 and EGF receptor are boxed. Positions in the other sequences that match the Dsrc13 sequence are shown in capital letters. Lower-case letters in the Dsrc13 sequence indicate that no other sequence matches at that position. The numbers on the right-hand side indicate the homology of that sequence with Dsrc13. The sources of the sequence data were as follows: D*ash*, ref. 7; v-*abl*, ref. 7; Dsrc4, ref. 9; v-*fes*, ref. 21; v-*fps*, ref. 22; v-*src*, ref. 23; Dsrc, ref. 7; v-*yes*, ref. 24; v-*fms*, ref. 25.

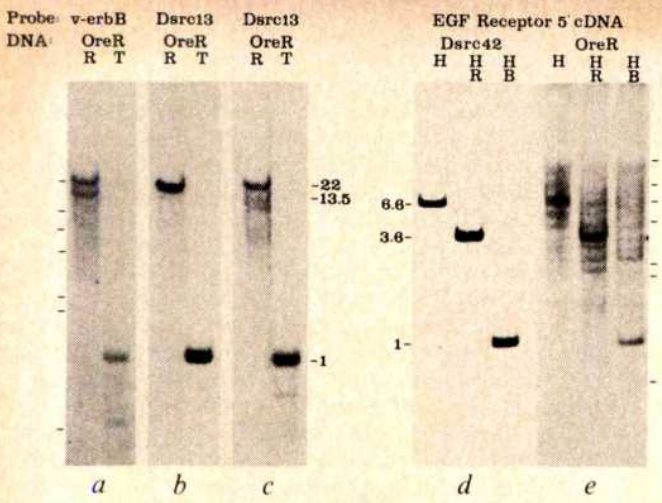

Fig. 4 Southern blot hybridization analysis of cloned and genomic sequences. In *a–c*, Southern blots of Oregon R genomic DNA cleaved with either *Eco*RI (R) or *Taq*I (T) were hybridized with the v-*erb-B* *Bam*HI fragment probe or the Dsrc13 *Eco*RI fragment probe. In *d* and *e*, respectively, Southern blots of whole phage DNA from the Dsrc42 clone (see Fig. 1) or Oregon R genomic DNA cleaved with *Hin*dIII (H), *Hin*dIII plus *Eco*RI (HR) or *Hin*dIII plus *Bam*HI (HB) were hybridized with the *Eco*RI/*Nae*I probe specific for the extracellular domain of the human EGF receptor cDNA clone. With the exception of *b*, hybridizations were conducted as described in Fig. 1 legend; for *b*, the hybridization conditions were identical except that the temperature of hybridization was 67 °C. The dashes on the left and right sides of the figure indicate the positions of λ DNA cleaved with *Hin*dIII. The approximate sizes of the hybridizing DNA fragments noted in the text are also shown.

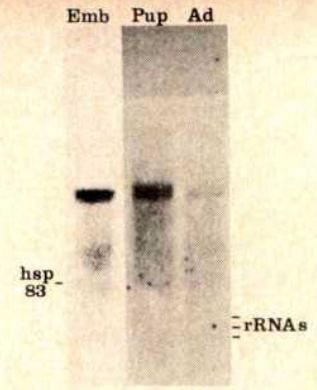

Fig. 5 RNA expression of Dsrc13 sequences. Approximately 5-μg samples of poly(A)-containing RNA from an 18-h collection of *Drosophila* embryos (Emb), mid-metamorphic stage animals (Pup) and adult flies (Ad) were electrophoresed through formaldehyde/agarose gels, blotted and hybridized with Dsrc13 probe as described previously[26]. The positions of the rRNA species (2 kb, 1.9 kb and 1.7 kb) were determined by staining of the nitrocellulose filter. The position of the *hsp83* mRNA (3.05 kb) was determined by hybridization with cloned *hsp83* gene sequences[27].

was essentially the same as in the cloned DNA (Fig. 4*e*). In each digest, the unique band of hybridization in the cloned DNA corresponded in size to the major band of hybridization in genomic DNA. We therefore conclude that the major genomic sequence detected by hybridization with the extracellular domain probe of EGF receptor is located on the same cloned DNA segment that has homology with the kinase domain of the EGF receptor. Additional nucleotide sequencing experiments are in progress to confirm the identity of the sequences in the region of our *Drosophila* clones which hybridize with the *Eco*RI/*Nae*I probe. Hybridization of the *Eco*RI/*Nae*I probe to additional genomic sequences was also observed (Fig. 4*e*), but their nature is unknown. However, the v-*erb-B* probe also detected genomic sequences not present on our cloned DNA segments (Fig. 4*a*). Taken together, these results suggest that other genomic sequences related to both domains of the EGF receptor may be responsible for the observed hybridization.

As the Dsrc13 probe contains sequences from an amino-acid-coding region and does not contain repeated sequences detectable in high-stringency hybridization conditions (Fig. 4*b*), this probe was used to test for RNA expression of the putative EGF receptor gene, and readily revealed a poly(A)-containing transcript of 6 kb in embryos, pupae and adults (Fig. 5). In pupal RNA, this band seems to be a closely spaced doublet. These results suggest that the sequences exemplified by the Dsrc13 clone represent a functional *Drosophila* gene.

In vertebrate cells, the mitogenic activity of EGF is transmitted through the EGF receptor. Because of its different developmental programme, the study of these sequences in *Drosophila* offers a different perspective of EGF receptor function. For the first 2 h of *Drosophila* development, there are virtually continuous rounds of chromosome and nuclear divisions although there are no cells and no cell divisions. At the blastoderm stage, the fate of cells is determined such that some cells, the imaginal cells, will divide mitotically until the adult is formed during metamorphosis. Other cells that give rise to larval tissues will not divide during the 4 days of larval life although chromosome duplication does continue. Thus, there are fluctuations in the mitotic states of cells in *Drosophila* that have no counterpart in vertebrate systems. We plan to exploit these differences to enhance our understanding of EGF receptor structure and function and its involvement in *Drosophila* development.

We thank W. Bender for providing the *Drosophila* λ phage library, A. Mahowald for providing the *Drosphila* embryos, J. M. Bishop for the use of the recombinant plasmid containing v-*erb-B* sequences, and A. Ullrich for the use of the plasmid containing EGF receptor sequences. This work was supported by grants to S.C.W. from the National Cancer Institute and the March of Dimes Birth Defects Foundation. Central research facilities at the Worcester Foundation for Experimental Biology were supported in part by grants from the NCI (CA-12708) and the Mimi Aaron Greenberg Memorial Cancer Research Fund.

Note added in proof: Nucleotide sequence analysis of the Dsrc16 clone centred around the leftmost *Bam*HI site (Fig. 1) has revealed a region having amino-acid sequence homology with the extracellular domain of the human EGF receptor. Within a 260-base pair region, the overall amino-acid sequence homology is ~32% but includes a region in which 9 of 11 amino acids match (amino acids 373–383 in the human sequence[10]).

The introduction of cloned probes to follow the segregation of DNA restriction fragment length polymorphisms (RFLPs) has led to a revival of mendelian genetics in attempts to map the human genome[1]. In the mouse, however, it has often proved difficult to detect an RFLP with a DNA probe between different inbred strains of the laboratory mouse. To circumvent this problem, we have used two species, *Mus musculus domesticus* and *Mus spretus*[2] which interact as sympatric species[3] but can be interbred under laboratory conditions[4]. Because of the relative evolutionary distance between these species, they exhibit polymorphism at many more loci than do different strains of the usual *M. m. domesticus* laboratory mouse[2]. This is also observed at the DNA level when the sizes of restriction fragments encoding a specific gene are compared[5]. We have used these RFLPs between *M. m. domesticus* and *M. spretus* to follow the segregation of genes encoding different isoforms of myosin alkali light chains in the backcross progeny between these species and to compare this with that of other contractile protein genes. No linkage between these genes was observed.

We have characterized several DNA sequences which serve as specific probes for genes encoding different isoforms of myosin alkali light chains in the mouse, including the isoforms of fast skeletal muscle ($MLC1_F/MLC3_F$)[5], cardiac ventricular muscle ($MLC1_V$), which is also the major isoform expressed in slow skeletal muscle ($MLC1_S$)[6], and cardiac atrial muscle ($MLC1_A$), also expressed in fetal skeletal and ventricular muscle ($MLC1_{emb}$)[7,8]. The two light chains, $MLC1_F$ and $MLC3_F$, are encoded by a single functional locus, from which a processed pseudogene has been generated in some mouse species (for example, *Mus musculus*); this is absent from *M. spretus*[5]. The other isoforms are encoded by unique loci[6,8]. These probes reveal fragments of different sizes in the DNA of inbred lines of *M. spretus* (SPE/Pas) and of *M. musculus* (DBA/2) on restriction with many different enzymes, which thus characterize allelic forms of the genes.

The segregation of the myosin light-chain (MLC) alleles in 42 offspring from a back-cross is presented in Table 1 and analysed in Table 2. An example of such an experiment with the $MLC1_A$ ($MLC1_{emb}$) gene is shown in Fig. 1. There is no co-segregation of the genes encoding $MLC1_F/MLC3_F$, $MLC1_A$ ($MLC1_{emb}$) or $MLC1_V$ ($MLC1_S$), thus, there is no genetic linkage. In this backcross analysis, linkage would have been detected for genes up to 30 centimorgans (cM) apart, with a 99% confidence limit[9]. Twenty-one previously localized polymorphic markers[10], covering about half of the mouse genome, have been analysed for their segregation in the same back-cross. Comparison with the segregation of the myosin light-chain genes demonstrates linkage of the gene for $MLC1_F/MLC3_F$ to *Idh-1* (chromosome 1), for $MLC1_V$ ($MLC1_S$) to *Es-14* (chromosome 9) and for $MLC1_A$ ($MLC1_{emb}$) to *Es-3* (chromosome 11). Therefore, these myosin light-chain genes are located on different mouse chromosomes.

The localization of the $MLC1_F/MLC3_F$ gene was confirmed by the analysis of B × D recombinant inbred strains derived from

Table 1 Segregation of the contractile protein genes and of biochemical markers in the back-cross

The animals are scored as homozygous for the *musculus* alleles (−) or heterozygous (+). ND, not determined. Animals 1-20 are females, 21-42 are males. *Idh-1*, *Es-3* and *Es-14* were analysed as described in ref. 20. The segregation of *Hba* was analysed using a *Hin*dIII RFLP detected with an α-globin cDNA[21]; see Fig. 1. Similarly, the $MLC1_F/MLC3_F$ gene was analysed using *Eco*RI or *Bcl*I (blot washing at 45 °C), the $MLC1_V$ ($MLC1_S$) gene using *Bam*HI (blot washing at 45 °C), the MHC_F gene using *Bgl*I (blot washing at 72 °C), the α-cardiac actin gene using *Bcl*I or *Sac*I (blot washing at 65 °C) and the α-skeletal actin gene using *Xba*I or *Bgl*I (blot washing at 72 °C). The $MLC1_A$ ($MLC1_{emb}$) gene was analysed using *Bam*HI as illustrated in Fig. 1.

Fig. 1 *a*, Outline of the backcross strategy between inbred strains of *M. m. domesticus* (DBA/2) and *M. spretus* (SPE/Pas). 42 offspring were analysed for the segregation of RFLPs and 37 for the segregation of biochemical markers. The F_1 males are sterile[22] because of a limited number of loci (J.-L.G., unpublished results). *b*, An example of the segregation of the RFLPs for the $MLC1_A$ ($MLC1_{emb}$) gene. DNA was extracted from the spleen of the parental animals and of the offspring, restricted and analysed on blots as described in ref. 23; 5 μg of each DNA sample were restricted with *Bam*HI and blotted onto nitrocellulose. Blots were probed with the $MLC1_A$ ($MLC1_{emb}$) cDNA labelled by nick-translation as described in ref. 23, then washed in 0.1×SSC at 65 °C before autoradiography. Lanes DBA/2 and Spretus correspond to the parental DNA samples, lanes 1 to 14 to the first 14 back-crosses analysed.

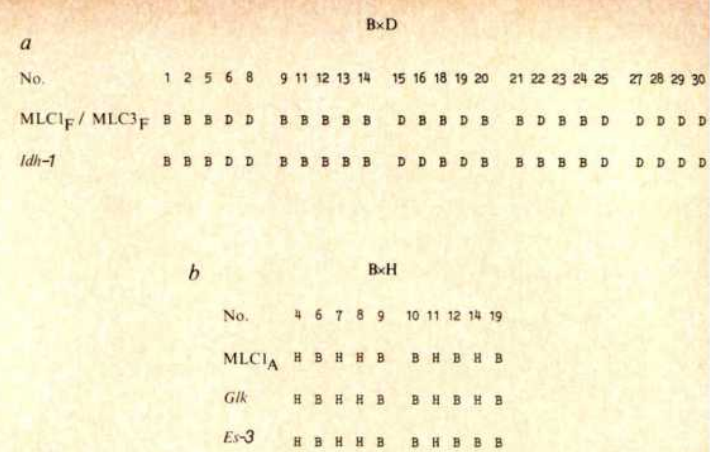

Fig. 2 *a*, Co-segregation of the $MLC1_F/MLC3_F$ and *Idh-1* loci in the B×D recombinant inbred strains. *b*, Co-segregation of the $MLC1_A$ ($MLC1_{emb}$), *Glk* and *Es-3* loci.
Methods. *a*, A *Pst*I RFLP was defined for the myosin light-chain locus between the parental strains. DNA samples of the 24 recombinant inbred strains were purchased from the Jackson laboratory (Bar Harbor) and analysed as described in Fig. 1 legend. *b*, A *Hin*fI RFLP for the MLC locus was used in the same way to follow the segregation of the gene in the 10 B×H recombinant inbred strains. The segregation pattern of *Idh-1*, *Glk* and *Es-3* in these recombinant inbred strains is described in ref. 10.

C57BL/6J (B) and DBA/2J (D) *M. m. domesticus* parental strains[9], in which allelic forms of *Idh-1* segregate[10] (Fig. 2). Of 24 recombinant inbred strains analysed, only two do not show a co-segregation between $MLC1_F/MLC3_F$ and *Idh-1*, indicating a genetic distance of ~2 cM between these loci[9]. Similarly, in B×H recombinant inbred strains derived from C57BL/6J (B) and C3H/HeJ (H)[9], the $MLC1_A$ ($MLC1_{emb}$) locus co-segregates with *Glk* and, with one exception, with *Es-3* (Fig. 2).

The segregation of the genes encoding the α-skeletal and α-cardiac actins[11,12] and a fast skeletal muscle isoform of the myosin heavy chain (MHC_F)[13] was analysed in the same back-cross. Our results confirm that these genes segregate independently, as expected from the analysis of somatic cell hybrids, which allocates them to different mouse chromosomes[14–16]. In addition, we show that they are not linked to myosin light-chain genes in the mouse genome, except for a loose linkage (70% co-segregation) between the MHC_F and $MLC1_A$ ($MLC1_{emb}$) loci, which are both allocated to chromosome 11 (Tables 1, 2). This linkage suggests that the MHC_F gene lies in the middle of chromosome 11 and that the genes are arranged in the order *Hba*/MHC_F/$MLC1_A$/*Es-3* from the centromere on this chromosome.

We conclude, therefore, that the co-expression of contractile protein genes in an adult or fetal, skeletal or cardiac muscle[17] does not require a structural proximity of these genes. Furthermore, the genes coding for different alkali myosin light-chain isoforms, which have probably arisen by gene duplication, have been dispersed in the mouse genome, in contrast to some other multigene families such as that of the β-globin genes[18].

This represents the first report of gene mapping based on the analysis of RFLP segregation in crosses between different mouse species. It is important to show that the evolutionary distance between them does not introduce a bias. For the following reasons, we argue that this is not the case. First, no gross reorganization of the chromosomes has been observed between these species by cytological methods (H. Winking, personal communication). The fact that they breed and give rise to viable and fertile offspring supports this observation. Second, the genes linked on the mouse genetic map co-segregate in our crosses and those which are not linked do not (for example, there are only 8/37 recombinants between *Amy-1* and *Adh-1* (chromosome 3) and 8/37 between *Pgm-1* and *Alb-1* (chromosome 5); see also ref. 19). In addition, our localizations for the $MLC1_F/MLC3_F$ and $MLC1_A$ ($MLC1_{emb}$) genes have been confirmed using recombinant inbred strains.

The type of analysis presented here has several advantages over the use of recombinant inbred strains: (1) The use of

Table 2 Analysis of the segregation of alleles in the back-cross

	$MLC1_A$	$MLC1_V$	α-Skeletal actin	α-Cardiac actin	MHC_F	*Idh*-1	*Es-3*	*Es-14*	*Hba*

Numbers refer to the numbers of co-segregants per total number of animals analysed.

back-crosses extends the analysis over longer distances (30 cM), whereas recombinant inbred strains tend to keep linked only those loci that are very close together[9]. (2) During the generation of recombinant inbred strains, certain associations of genes may be favoured or selected against, resulting in a nonrandom segregation of loci not observed in a back-cross. (3) The use of distantly related species increases the probability of finding an RFLP for a given gene, so that any gene for which a complementary DNA (cDNA) is available can be analysed.

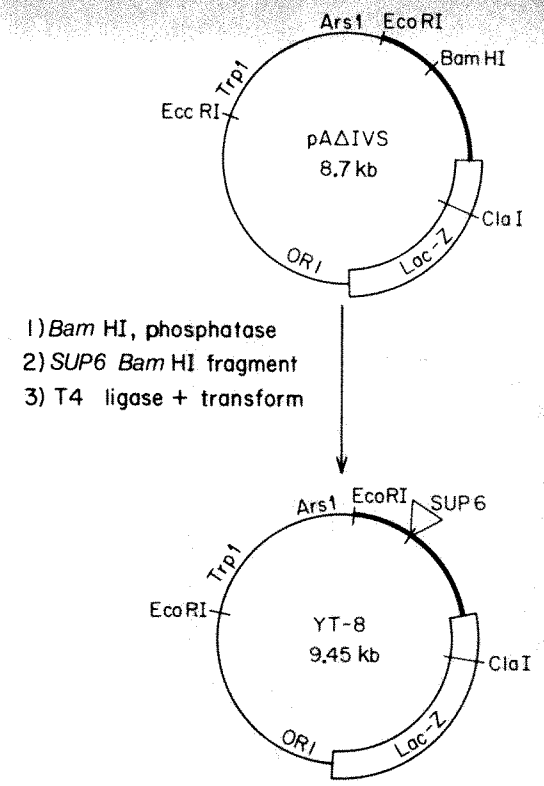

Fig. 1 Construction of plasmid YT-8. Construction of the actin/β-galactosidase fusion plasmid with the actin intron removed (pAΔIVS) has been reported elsewhere[8]. Plasmid YT-8 was constructed by inserting a 0.75-kb *Bam*HI fragment containing the *SUP6* tRNA gene into the *Bam*HI site of pAΔIVS. The thick line indicates the segment containing the yeast actin gene and its flanking sequences.

A test for intron function in the yeast actin gene

Many eukaryotic genes contain intervening sequences (IVS)[1,2], but the rationale for their existence remains a mystery. Previous studies done in our laboratory demonstrated that the intron in a yeast tRNA^{Tyr} gene, *SUP6*, does have a function[3,4]. We used the same approach to determine the role of introns in nuclear genes encoding messenger RNAs. A single actin gene with one intron exists in *Saccharomyces cerevisiae*[5,6]. The level of actin in yeast appears to be crucial to viability: either too much or too little actin inhibits growth[7]. Therefore, small effects on synthesis of actin protein resulting from the removal of the actin gene intron would be expected to cause measurable changes in cell growth. In the present study, an intron-deleted actin gene was constructed *in vitro* and was used to replace the single resident actin gene in a haploid strain. Analysis of the cells carrying the intron-deleted actin gene shows that the intervening sequence is not essential for actin gene expression.

§ Present address: Laboratorium für Molekulare Biologie—Genzentrum, Martinsried, FRG.

Deletion of the intron from a yeast actin/β-galactosidase fusion gene (in pAΔIVS) has been reported previously[8]; this plasmid was modified further by inserting a 750-base pair (bp) *Bam*HI fragment containing the *SUP6* tRNA gene into the unique *Bam*HI site upstream of the actin gene (Fig. 1). *SUP6*, a tyrosine-inserting ochre suppressor, provides a selectable marker for chromosomal integration (Fig. 1) through selection for Leu$^+$ and His$^+$ transformants by *SUP6* suppression of the ochre mutation in those genes. Plasmid DNA from YT-8 (plasmid pAΔIVS with the *SUP6* gene inserted in the *Bam*HI site) was digested with the restriction enzymes *Eco*RI and *Cla*I, then used to transform the haploid yeast strain DBY874 [*α his5-2* (oc), *leu2-1* (oc), *can1-100* (oc), *ura3-52*, *trp5-48* (oc)]. Transformants were initially selected on the basis of their ability to grow on leucine-deficient media. To distinguish from possible Leu$^+$ revertants, the candidates were rescreened for their ability to grow on histidine-deficient media. An alteration of the actin locus could be generated by either genetic recombination (a double crossover between the incoming fragment and the homologous region on the actin gene) or gene conversion (heteroduplex formation between the incoming actin sequences and genomic DNA at the actin locus); either of these mechanisms, or a combination of the two, can be invoked to explain the changes observed in the recombinant actin genes[9].

To determine whether an intron-deleted actin gene had been created by this procedure, genomic DNAs from candidate transformants and from the untransformed parent were compared by Southern blot analysis (Fig. 2). When wild-type yeast DNA is digested with *Eco*RI and *Hin*dIII, two fragments of 1.6 and 2.2 kilobases (kb) are generated which hybridize with a radioactive actin-specific probe[5,6]. As the 1.6-kb fragment contains only the 3′ half of the actin gene, it will remain unchanged in the transformants. The 2.2-kb fragment includes the 5′-flanking

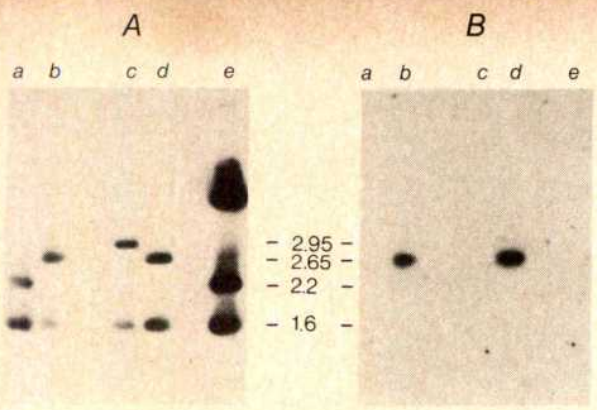

Fig. 2 Southern blot analysis of genomic DNA from DBY874 and transformants 513-A, -V and -L. *A*, Genomic DNA was digested with the restriction enzymes *Eco*RI and *Hin*dIII. After electrophoresis in a 1% agarose gel, DNA was transferred to a nitrocellulose filter and hybridized with nick-translated pYact1 (3.8-kb *Eco*RI fragment containing the actin gene in pBR322; refs 5, 6). All tested strains have the smaller 1.6-kb *Eco*RI/*Hin*dIII fragment in common, whereas the size of the larger *Eco*RI/*Hin*dIII fragment (upper band) differs: *a*, DBY874, 2.2 kb (same size as the wild-type fragment in pYact (*e*); *b*, *d*, 513-A and 513-V, respectively, 2.65 kb (insertion of the *SUP6* gene and deletion of the actin intron); *c*, 513-L, 2.95 kb (insertion of the *SUP6* gene, but with the actin intron present). *B*, The filter in 2*A* was reprobed with a [5'-^{32}P]-labelled 17-base oligonucleotide specific to the actin exon–exon junction.

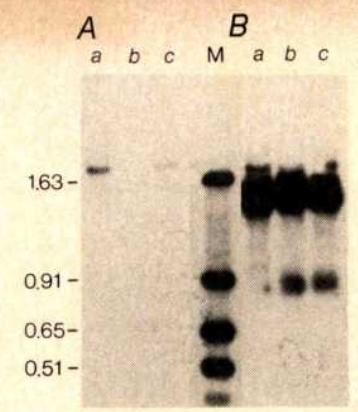

Fig. 3 Northern blot analysis of poly(A)$^+$ RNA from DBY874 and transformants 513-A and 513-L. *A*, Hybridization of poly(A)$^+$ RNA with a nick-translated actin intron-specific fragment (204-bp *Xho*I/*Cla*I fragment of pYact I[5,6]). Actin precursor mRNA (~1,700 nucleotides) is detected only in DBY874 (*a*) and the transformant 513-L (*c*). No actin precursor mRNA is found in strain 513-A (*b*). *B*, The filter used in *A* was rehybridized with nick-translated actin DNA (3.8-kb *Eco*RI fragment of pYact I). Actin mRNA (~1,400 nucleotides) is present in similar amounts in all strains tested. (The probe pYact I also contains a region which hybridized with RNA from the YP2 gene, 800 nucleotides long[11,12].)

Methods. RNAs from DBY874 (*a*), 513-A (*b*) and 513-L (*c*) were isolated from cells grown to mid-logarithmic phase (A_{600} = 2–5) by hot phenol extraction. Poly(A)$^+$ RNA was obtained by oligo(dT)-cellulose chromatography. Glyoxylated poly(A)$^+$ RNA (10 μg) from each strain was electrophoretically separated on a 1.8% agarose gel in 10 mM phosphate buffer[13]. Nucleic acids were transferred to nitrocellulose filters and hybridized according to the procedure of Thomas[14]. Lane M corresponds to 5'-labelled *Alu*I and *Hin*fI fragments of pBR322 serving as size markers.

region and a large portion of the actin gene; the size of this band will vary in transformants because it contains the inserted *SUP6* gene and the actin intron region. Two different classes of transformants were found based on the size of the larger *Hin*dIII/*Eco*RI fragment (Fig. 2*A*): (1) a 2.95-kb band (in 513-L, which has the *SUP6* gene inserted upstream of the actin gene but still contains the actin intron) and (2) a 2.65-kb band (in 513-A and 513-V, which have the *SUP6* gene inserted and no longer contain the intron). No plasmid sequences were present in the transformants (data not shown). Definitive proof of the removal of the actin intron was obtained by hybridization of genomic DNA digested with *Hin*dIII and *Eco*RI with a [5'-^{32}P]-labelled 17-base oligonucleotide specific to the actin exon–exon junction[8]. Only the intron-deleted strains hybridized with the labelled oligonucleotide (Fig. 2*B*).

Expression of the intron-deleted actin gene was analysed by Northern blot analysis of actin-specific mRNA from the wild-type strain and from transformed strains (Fig. 3). Using a nick-translated restriction fragment specific for the actin intron, no actin precursor mRNA could be detected in RNA prepared from the transformant 513-A, whereas it was present in RNA from wild-type strains and from the strain 513-L (Fig. 3*A*). Hybridization of actin-specific DNA, labelled by nick-translation, with poly(A)$^+$ RNA showed that the relative amounts of actin mRNA were roughly equivalent in the strains with and without the actin intron and *SUP6* gene (Fig. 3*B*); however, the level of actin has not been analysed. Further, the strains 513-A and 513-V grew at a rate similar to that of their counterpart 513-L (their doubling times are within 5% of each other).

As the level of actin protein is critical for cell survival, strains 513-A and 513-V must have normal amounts of actin protein[7]. Thus, the deletion of the intervening sequence does not affect the level of actin mRNA in the cell. However, small differences in the level of mRNA and/or actin cannot be ruled out. In addition, there is no apparent effect on sporulation. Diploid cells homozygous for the intron-deleted actin gene sporulate to generate four viable spores (R. Parker, personal communication).

We conclude from this experiment that the intron in the yeast actin gene does not have an observable function. It is possible that the role of the intron is too subtle to be observed in laboratory conditions of growth or that the intron, while having evolutionary significance, has no present role. To conclude that this is true for all yeast genes that contain introns would of course be premature, but there exist strains in which mitochondrial introns have been removed[10] with no observable effect.

Insertion of a selectable marker upstream of the gene of interest may serve as a general method for efficiently transferring mutations into the yeast genome.

DBY874 was from D. Botstein's laboratory. We thank R. Parker for sharing his sporulation results, and P. Johnson for his helpful advice. This research was supported by NIH grant GM 32637. H.D. was a recipient of an EMBO fellowship.

Does *Paramecium primaurelia* use a different genetic code in its macronucleus?

François Caron & Eric Meyer

Centre de Génétique Moléculaire,
Centre National de la Recherche Scientifique,
91190 Gif-sur-Yvette, France

It has long been known that messenger RNAs (mRNAs) of ciliates and in particular of *Paramecium* are not translated well in heterologous *in vitro* translation systems[1–4]. Recently, we have demonstrated for *Paramecium primaurelia* that this phenomenon results from the presence of well-defined blocking sites in the coding sequences of almost all mRNAs, and that these sites are an intrinsic feature of the primary as opposed to the secondary structure of the mRNAs[5]. Here we show that both the gene and the mRNA for the G surface antigen of *P. primaurelia* contain numerous TAA and TAG codons scattered throughout their coding sequences. We propose that these codons do not represent termination codons in *P. primaurelia* but instead code for glutamic acid or glutamine and that the *in vitro* translation of *Paramecium* mRNAs is blocked by their presence.

The G surface antigen is one of the set of surface antigens expressed by *P. primaurelia* in a mutually exclusive manner[6,7]. It is a highly abundant protein covering the whole surface of the cell, and comprises a unique polypeptide chain of relative molecular mass 250,000–300,000 (refs 8, 9). Its mRNA is ~8 kilobases (kb) long and can be detected readily on an RNA gel[4,5,10]. From a genomic library of macronuclear DNA, two *Eco*RI fragments of 5.6 and 1.2 kb, EG1 and EG2, respectively, were selected[5]. Direct proof that the EG1 and EG2 fragments contain sequences coding for the G surface antigen was obtained by selectively hybridizing them with G-antigen mRNA[5,10] and by the direct expression in *Escherichia coli* of subfragments of EG1 and EG2 sequences (E.M., F.C. and A. Baroin, in preparation, and see below for EG2): at least two subfragments, shown in Fig. 1, code for antigenic determinants of the G antigen.

Southern blotting of genomic DNA shows that the G-antigen gene is situated between a *Bam*HI site and the end of a macronuclear chromosome 15.5-kb away; this region is unique in the genome (its restriction map is given in Fig. 1). The gene is oriented with its 3′ end towards the end of the chromosome. By Northern blotting of total RNA from G-expressing paramecia, EG2 is shown to be the most downstream *Eco*RI fragment of the macronuclear chromosome hybridizing to the mRNA of the G antigen (not shown). The precise location of the 3′ end of the transcript was determined by S_1 mapping (not shown) and it is found to lie 70 bp downstream from the *Eco*RV site of EG2 (see Fig. 1). Upstream from this point, the EG2 sequence is completely protected by the mRNA in S_1 protection experiments (not shown).

The entire EG2 fragment was sequenced by the Maxam–Gilbert technique[11]. The strategy used for sequencing is shown in Fig. 1, as is the noncoding strand. This sequence is remarkable in that two regions can be distinguished clearly on the basis of their A+T content (see Fig. 1): the A region at the 5′ end (the first 1,137 base pairs, bp) contains 62% A+T with a marked 3-bp periodicity in their distribution (see Fig. 2*b*) whereas the last 105 bp at the 3′ end (the B region) yields the significantly higher value of 82% A+T and no such periodicity. In organisms having A+T-rich genomes, coding regions usually have a much lower A+T content than noncoding regions and most

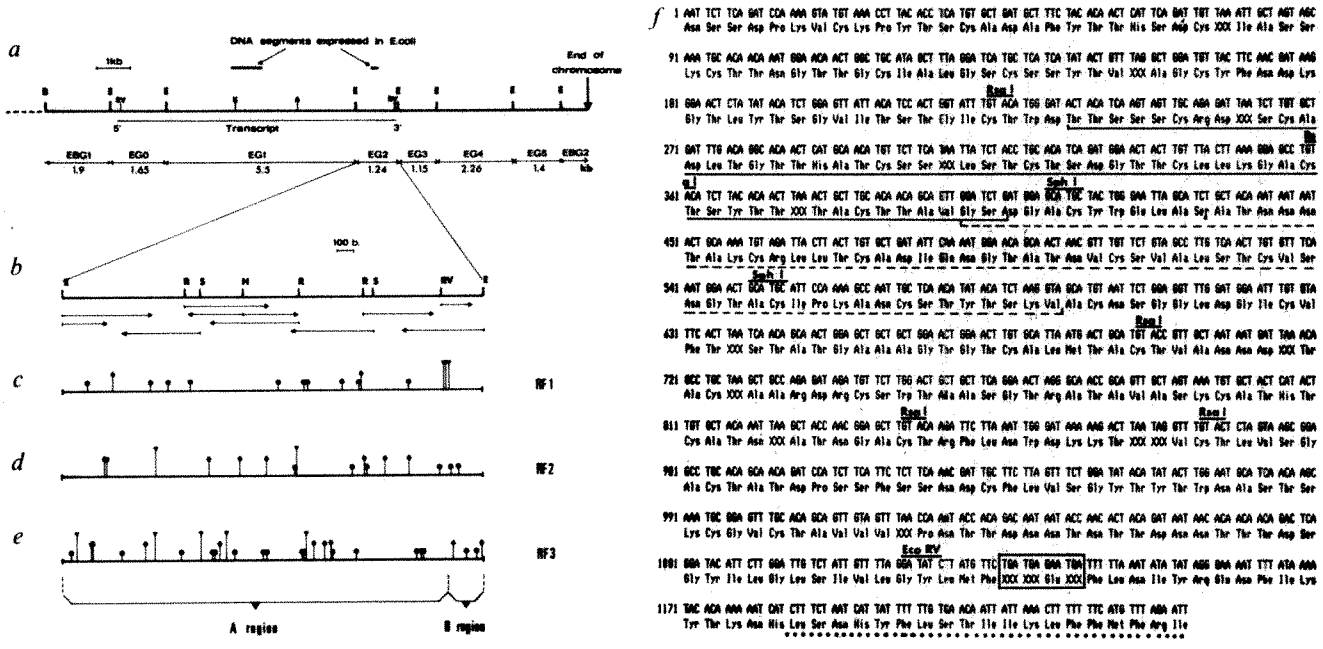

Fig. 1 Structure of the G surface antigen gene and sequence of its 3′ end. *a*, Map of the region of the macronuclear chromosome containing the G surface antigen gene (E, *Eco*RI; B, *Bam*HI; RV, *Eco*RV; A, *Ava*I; K, *Kpn*I; H, *Hin*dII; S, *Sau*3A). After addition of a synthetic *Bam*HI linker to the end of the macronuclear chromosome, we were able to clone the 15.5-kb *Bam*HI fragment in λ EMBL3 (ref. 24). The different *Eco*RI fragments of the cloned 15.5-kb fragment, named (from left to right) EBG1, EG0, EG1, EG2, EG3, EG4, EG5 and EBG2, were subcloned separately in plasmid pUC12 or pBR328. The position of the transcript was determined by S_1 mapping according to ref. 25: the 5′ end is localized in the EG0 fragment, and the 3′ end in the EG2 fragment. The EG2 fragment, which contains the 3′ end of the message, was sequenced (*f*) by the Maxam and Gilbert procedure[11]; the sequencing strategy is shown in *b*. *c–e*, The positions of the stop codons in the three possible reading frames: ●, TAA; ◆, TAG; and ▼, TGA. On the basis of % A+T content, two regions can be distinguished: the A region with 62% A+T and the B region with 82% A+T. *f*, The EG2 sequence. The 1,242-base DNA strand shown is the noncoding strand and the reading frame is RF1. The dotted line indicates the part of the EG2 sequence that is not protected by the mRNA; the dashed line indicates the DNA subfragment containing an antigenic determinant of the G surface antigen (see Fig. 3); solid line, the RNA sequence determined from the *Sph*I/*Sph*I fragment by the primer extension method (see Fig. 4). A cluster of three TGAs near the 3′ end (boxed) is located at the junction between the A and B regions.

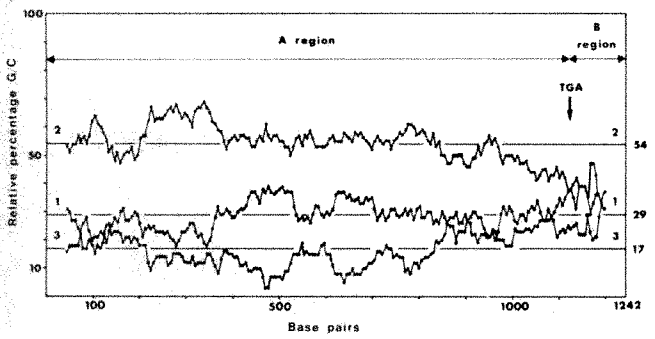

Fig. 2 Codon usage and frequency of G/C bases in the EG2 sequence. *a*, The codon usage in the A region is given for the three possible reading frames RF1, RF2 and RF3. Only RF1 displays a strong bias in favour of A or T at the third position. *b*, The frequency of G/C bases at the three triplet positions. Each point represents the mean value calculated for a 30-triplet fragment (curves 1, 2 and 3 give the relative percentages of G/C at the first, second and third positions, respectively, of the codons in RF1). The three lines are distinct in the A region of the sequence and tend to overlap in the B region. RF1 has the lowest percentage of G/C at the third position.

importantly are characterized by a 3-bp periodicity in A+T richness. As EG2 contains the 3′ end of the mRNA, the existence of these two very distinct regions suggests that region A could be the end of the coding sequence. However, the three possible reading frames RF1, RF2 and RF3 all contain scattered TAA, TAG and TGA codons, found every 80 bp on average (see Fig. 1). Yet, if one looks more carefully at the other codons used in the short open reading frames (in between two stop codons) in the A region, one finds that RF1, but not the other two reading frames, shows the following characteristics: (1) The 3-bp periodicity mentioned above falls so that the third base of each codon shows the strongest bias for A and T (see Fig. 2), characteristic of coding sequences in A+T-rich genomes. (2) The ratio of RNY to YNR codons, where R is a purine, N any base and Y a pyrimidine, is equal to 2.5 for the reading frame FR1 and 0.4 and 0.9 for RF2 and RF3 (see Table 1). It has been observed[12,13] that in many prokaryotic and eukaryotic genomes this ratio is >2 for coding frames and <1 for noncoding frames. (3) The amino-acid composition deduced from RF1 is remarkably close to that of the entire G surface antigen (see Table 1). χ^2 values calculated from the amino-acid composition of G surface antigen[14] are 47 for RF1, 740 for RF2 and 650 for RF3. The same calculation for the last 110 bp of the EG2 sequence (region b), whatever the reading frame, yields higher χ^2 values than for any 110-bp stretch of the A region in RF1 (see Table 1, column *i*, in which a comparison is made with the first 110 bp of the A region). (4) The nature of the stop codons in RF1 is also peculiar as only TAA and TAG codons are present in region A and a cluster of three TGA codons is located at the junction between A and B (see Fig. 1).

The above arguments, especially those concerning the RNY/YNR ratio, the 3-bp periodicity and the χ^2 values, strongly support the notion that, despite the presence of TAA and TAG triplets in RF1, the A region codes for part of the G antigen.

To obtain direct proof that the A region contains coding sequences and that RF1 is the proper reading frame, we used direct expression of DNA subfragments of EG2 in the expression vector λ gt11 to determine whether they code for antigenic determinants which can be recognized by antibodies against G surface antigen. EG2 was cleaved with the restriction enzyme *Rsa*I (see Fig. 1), and digested with exonuclease *Bal*31 to generate DNA subfragments of various lengths, which were then

Table 1 Amino-acid compositions of A and B regions of EG2 sequence

Amino-acid compositions deduced for the A region (columns *b*, *c*, *d*) and the B region (columns *f*, *g*, *h*) of the EG2 sequence in the three reading frames RF1 (*b*, *f*), RF2 (*c*, *g*) and RF3 (*d*, *h*) and for the first 110 bp of the EG2 sequence in RF1 (column *i*). The amino-acid composition of the G antigen[15] is given for comparison in columns *a* and *e*. χ^2 values and the RNY/YNR ratio are also given.

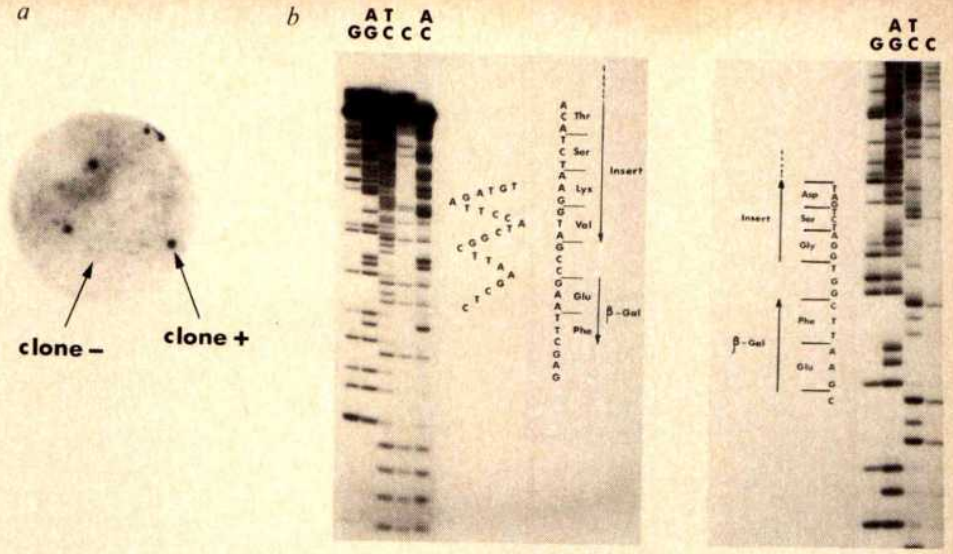

Fig. 3 Determination of the reading frame of the coding sequence of the G surface antigen. 50 μg of plasmid pEG2 (recombinant pBR328 plasmid containing the EG2 sequence at the *Eco*RI site) were digested to completion with the restriction enzyme *Rsa*I and then with 1 unit of *Bal*31 nuclease (Boehringer) at 37 °C. Aliquots of the reaction mixture were removed after 1, 2, 3, 4, 5, 6, 8 and 10 min of digestion, phenol-extracted and pooled for ethanol precipitation. After repair of the fragments with *E. coli* DNA polymerase, synthetic ^{32}P-labelled *Eco*RI linkers (P.L. Biochemicals) were ligated to their ends. After digestion with excess *Eco*RI, the DNA fragments (separated from the *Eco*RI linkers by two successive G50 column chromatography steps) were used to produce an expression library in the λ gt11 vector[15] at the *Eco*RI site. The library was screened with antisera-purified antibodies against purified G surface antigen, depleted of any anti-*E. coli* activities. Many positive recombinants were obtained and subcloned twice. ***a***, Positive (+) and negative (−) clones from a nitrocellulose replica of phage plaques after incubation with these antibodies, followed by labelling with ^{125}I-protein A (Amersham). The insert of one of the positive clones was subcloned in the two possible orientations in the pUC12 vector and its sequence determined by the Maxam and Gilbert technique[11] from both ends; it corresponds exactly to the sequence indicated by a dashed line in Fig. 1. Special care was taken to establish the sequence around the two *Eco*RI junctions as it gives the reading frame of the coding sequence of the insert (see text): the two recombinant plasmids bearing the insert in either of the two possible orientations were labelled at the *Bam*HI site, which is contained in the pUC12 polylinker 18 bases from the *Eco*RI site, and were sequenced from the *Bam*HI site towards the *Eco*RI site by the Maxam–Gilbert technique[11]. The two 20% acrylamide sequencing gels in ***b*** show that the reading frame of the insert is RF1, as deduced from that of the β-galactosidase.

inserted into the λ gt11 β-galactosidase expression vector[15]. Recombinants synthesize hybrid proteins made up of β-galactosidase and part of the polypeptide chain of the G surface antigen, provided the subfragments encode part of the G antigen and are inserted in the correct orientation and reading frame. Furthermore, if the expressed part of the G surface antigen contains an antigenic determinant, the clones synthesizing hybrid proteins can be detected directly by using antibodies against G antigen.

We obtained recombinant clones synthesizing polypeptides that reacted with antibodies against G antigen; one of these clones has been analysed in detail (see Fig. 3). The sequence of the insert is indicated by a dashed line in Fig. 1; this sequence is unique in EG2 and in the entire 15.5-kb fragment. By sequencing the junctions around the *Eco*RI sites, the reading frame of the insert can be deduced from that of β-galactosidase. From the sequences shown in Fig. 3, we conclude that RF1 is the correct reading frame of the G antigen.

Although it is clear that the sequence marked by a dashed line in Fig. 1 contains an antigenic determinant of the G surface antigen and that the open reading frames surrounding this fragment are probably part of the coding sequence as shown above, the punctuation of the coding sequence with TAA and TAG stop codons remains puzzling. One possible explanation is that they are removed by splicing. In order to demonstrate that this is not the case, we sequenced the cytoplasmic mRNA by the primer extension method[16], using as primer the *Sph*I/*Sph*I fragment included in the fragment expressed in *E. coli* (see Fig. 1). The sequence of the mRNA (Fig. 4) corresponds exactly to the sequence underlined with a solid line in Fig. 1. We conclude from these data that TAA and TAG codons are present in the reading frame of the coding sequence of the G-antigen mRNA.

Thus, TAA and TAG do not represent termination codons in *P. primaurelia*. The simplest explanation of the results is that they code for amino acids; other possible interpretations seem highly unlikely. For example, it could be argued that the gene we have cloned is a pseudogene[17] and that the true gene does not contain TAA and TAG triplets. This interpretation is not plausible for the following reasons: (1) Our S_1 mapping (not shown) and RNA sequencing experiments indicate that the cloned gene is transcribed abundantly. (2) If the cloned gene is a pseudogene, it must share large segments of homology with the true gene[17]. S_1 protection experiments (not shown) performed with EG1, EG2 or subfragments of these have never yielded anything other than a single protected fragment, indicating that the cloned gene and the true gene would differ at most by local changes not revealed by S_1 protection experiments. The 195-bp *Sph*I/*Sph*I primer, which does not contain TAA and TAG codons and which is, moreover, included in a 336-bp fragment coding for an antigenic determinant of the protein, should also hybridize with the mRNA of the true gene. As the sequence of the cloned gene alone is read and as it is read without ambiguity (see Fig. 4), the true gene should be transcribed at a much lower rate than the cloned gene (that is, at an undetectable level), which is highly unlikely for such an abundant protein. (3) Southern blots of total DNA of *Paramecium* and of the 15.5-kb cloned fragment cut with various restriction enzymes and probed with EG1 or EG2 fragments have always been found to be identical (not shown); this is at variance with the frequent observation that pseudogenes and true genes give rise to different sets of bands on Southern blots[17]. (4) The 10 TAA and 2 TAG codons in the EG2 sequence do not seem to be generated by the random mutations expected in a pseudogene. Indeed, despite their presence, the reading frame is unchanged over the whole length of the coding sequence.

Our results lead us to the following conclusions: (1) The fact that TAA and TAG codons are interspersed in the coding sequence (see accompanying paper[18]) may explain the blocking of *in vitro* translation of *Paramecium* mRNAs. (2) The localization of the three TGAs in a cluster of four codons just before the end of the transcript, and at the junction between the A and B regions of the gene, suggests strongly that TGA is a termination codon in *Paramecium*. Note that the few genes sequenced to date in ciliates[19–21] all use TGA termination codons. (3) If TAA and TAG are coding triplets in *Paramecium*, we propose that they code for glutamic acid or glutamine on the basis of their important contributions (30%) to the χ^2 value. We do not think that many other changes in the *Paramecium* codon assignment

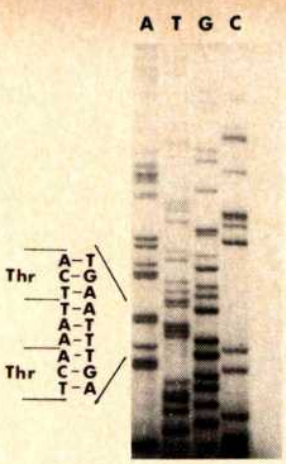

Fig. 4 RNA sequencing gel obtained from the *Sph*I/*Sph*I fragment by the primer extension method. Plasmid pEG2 (15 μg) was cut with *Sph*I and the fragments generated were labelled at their 5′ ends with [γ-^{32}P]ATP using polynucleotide kinase. The 138-bp long *Sph*I/*Sph*I fragment contained in EG2 (see Fig. 1) was purified on a polyacrylamide gel; 25% of the recovered probe and 75 μg of total RNA from G-expressing paramecia were ethanol-precipitated and resuspended in 80 μl of 80% formamide hybridization buffer[16]. The solution was warmed to 80 °C before being transferred quickly to a 60 °C water bath, the temperature of which was allowed to cool down to 30 °C over 2–3 h. Nucleic acids were precipitated with ethanol and polymerization was performed with reverse transcriptase (Life Science) and a mixture of the four deoxy- and dideoxynucleotides[16]. Part of the 6% acrylamide sequencing gel shown gives the RNA sequence around the first TAA codon upstream of the primer.

have occurred as translation of the EG2 sequence according to the universal code leads to a good overall agreement with the amino-acid composition of the G antigen. Direct proof that the TAA and TAG triplets encode amino acids in *Paramecium* has yet to be obtained, and would best comprise a direct comparison of the sequence of a protein with that of its gene, and the demonstration that transfer RNAs bearing anticodons to TAA and TAG triplets exist.

Some evidence that TAA encodes an amino acid in *Tetrahymena*[22] and *Stylonichia*[23] has been reported recently; this deviation from the universal code might be peculiar to all ciliates. It would be interesting to know whether it is linked to the existence of nuclear differentiation in ciliates and in particular whether the micronuclear and macronuclear copies of the genes are identical in this respect. This first example of an altered genetic code apart from that in mitochondria may provide new clues as to the evolution of the genetic code.

We thank John Preer, Claude Jacq and Michaël Katinka for helpful discussions and advice and Linda Sperling for critical reading of the manuscript. This work was supported in part by CNRS grant 900301. E.M. was supported by a fellowship from the MRI.

Deviation from the universal code shown by the gene for surface protein 51A in *Paramecium*

J. R. Preer Jr, L. B. Preer, B. M. Rudman & A. J. Barnett

Department of Biology, Indiana University, Jordan Hall 138, Bloomington, Indiana 47405, USA

The immobilization antigens (i-antigens) of *Paramecium*, large polypeptides of relative molecular mass ~300,000 (ref. 1), are located on the cell surface. Each i-antigen is encoded by a different unlinked gene, and no more than one gene is expressed at a time. The proteins and the mRNAs and genes encoding them are readily isolated[2,3]. Here we report the nucleotide sequence of three regions of the A i-antigen gene from stock 51 of *Paramecium tetraurelia*. Surprisingly, all reading frames contain TAA and TAG stop codons, even though there is evidence that one reading frame of these sequences codes for the i-antigen. We suggest that in *Paramecium* UAA and UAG code for amino acids, instead of serving as translational stops as they do in all other organisms.

λ SA-1 contains the whole transcribed portion of the A gene, ~8.4 kilobases (kb), together with the 5′ and 3′ flanking regions[3]. We sequenced 681 bases at the 5′ end of the gene and ~400 bases farther downstream (Fig. 1). The start of transcription has been localized previously in an S_1 protection experiment to a point ~450 bases to the left of a *Hin*dIII site[3]. In a similar S_1 nuclease experiment, using a shorter fragment and determining more precisely the size of the protected fragment on a sequencing gel (data not shown), the start of transcription was more precisely located 470 bases to the left of the *Hin*dIII site.

Each of the reading frames subsequent to the first ATG (+15) after the start of transcription (+1) has TAA or TAG stop codons

Table 1 Analysis of reading frames

Region of gene	Reading frame	No. of stop codons TAA	TAG	TGA	Fit to protein	RNY:YNR
−181 to +14	1	3	1	3	182	18:18
	2	5	0	3	102	16:20
	3	5	0	3	108	22:15
+15 to +681	1	4	2	0	26	76:34
	2	5	3	3	503	36:65
	3	5	5	12	404	52:64
+1,126 to +1,291	1	1	0	0	13	21:7
	2	2	0	0	205	4:15
	3	5	1	2	113	13:17
+5,486 to +5,692	1	3	1	0	17	30:8
	2	0	0	0	173	18:22
	3	4	1	5	147	6:24

Each of three possible reading frames is analysed for four regions of the 51A genes. The last three regions are believed to be translated. The number of stop codons, χ^2 fit to overall protein composition and ratio of RNY to YNR codons are given (R is purine, Y is pyrimidine and N is any base).

Fig. 1 Restriction map of the *Paramecium* DNA inserted into λ SA-1, and the nucleotide sequence of four regions of the 51A gene. H refers to *Hin*dIII; R is *Eco*RI. The arrow below the restriction map represents the transcribed portion of the gene. Sequences were obtained by using the Maxam-Gilbert technique[15] with minor exceptions both strands were sequenced at least twice.

(Table 1), except for the second reading frame of the 205 bases starting at position +5,485. It is our contention that all these regions (except for the sequences from −181 to +15 or somewhat beyond) are transcribed and their messages translated. For each region the true reading frame is thought to be the first one listed in Table 1, for the following reasons. (1) The presence of introns is unlikely as judged by S_1 nuclease experiments. In addition to the S_1 experiments already cited, comparable experiments (data not shown) have ruled out the possibility of introns in the first 2,900 bases. Indeed, the whole 8.4-kb transcribed region of the gene is just large enough to code for the poly(A)RNA with which it hybridizes[2,3], and either a TAA or a TAG occurs on average once every 100 bases. Moreover, the characteristic sequences at the boundaries of introns are not found.

(2) It is unlikely that the gene sequenced is a pseudogene or a regulatory gene. Correlations between the size and abundance of the i-antigens and a series of poly(A)$^+$ RNAs provide strong evidence that the RNAs code for the i-antigens[2]. The sequences in λ SA-1 hybridize to the RNA judged to be the mRNA for i-antigen A. Genomic Southern transfer experiments indicate that there is probably only one copy of the sequences in the SA-1 genome[3]. Furthermore, there are deletion mutations that eliminate these sequences and simultaneously eliminate the ability of stock 51 to produce i-antigen A[4]. We have crossed a strain of stock 51 bearing a deletion of the gene found in λ SA-1 with another stock of *P. tetraurelia* (stock 29) bearing the A allele. Alleles 29A and 51A determine i-antigens that can be distinguished serologically[1]. Antigen 29A and the deletion were found in the F_2 offspring in a 1:1 ratio, as expected if the deletion included the sequences responsible for serological specificity of the A protein. These results provide strong evidence that the gene found in λ SA-1 codes for the A protein.

Table 2 Amino acid frequencies

	Obs.	Exp.		Obs.	Exp.
Val	19	15	His	3	2
Leu	19	13	Asn + Gln	26	35
Ile	6	8	Ser	28	33
Phe	5	5	Thr	52	55
Ala	37	40	Gly	13	23
Pro	8	6	Cys	41	37
			Tyr	11	9
Trp	6	5			
Met	4	1	TAA	8	
Asp + Asn	46	39	TAG	3	
			TGA	0	
Glu + Gln	12	20			
Lys	20	15			
Arg	4	4			

Comparison of numbers of amino acids predicted from observed (obs.) codons with numbers expected from amino acid analysis of whole protein (exp.).

(3) It is unlikely that the sequences result from cloning artefacts. We have sequenced a small region of an independently isolated clone, λ SA-2, and find that it agrees with the sequence from +360 to +469 of λ SA-1 (Fig. 1), and includes a TAA and a TAG triplet.

(4) One of the three reading frames predicts an amino acid composition very similar to that estimated for immobilization antigen 51A by conventional amino acid analysis[5,6]; the fit was computed as a χ^2 value calculated from the observed composition of the whole protein and the composition of a given fragment deduced from the sequence (omitting TAA and TAG codons). These values are given in Table 1 for each reading frame for each region. As the sequences represent a significant portion of the whole protein and some of the classes of amino acids overlap, the assumption of independence does not hold, and a true χ^2 distribution is not expected. Nevertheless, χ^2 is a useful measure of the fit. In each case the first reading frame in each translated region has a very low χ^2 value and the other two frames predict a composition very far from the known composition of the whole protein.

(5) Codon usage suggests that the first reading frame is the correct one. Codon usage in all organisms is restricted such that the initial base in each codon is frequently a purine (R), the last base a pyrimidine (Y), while the middle base may be any base (N)[7]. The ratio of RNY to YNR codons is almost always ≥2:1 in true reading frames. The RNY/YNR ratios in Table 1 indicate that the first reading frame of each region represents the translated sequence.

To explore possible amino acid assignments for TAA and TAG, the frequencies of amino acids predicted by the observed codons for all three translated regions are given in Table 2, together with the numbers expected from the overall amino acid composition of i-antigen A. Ignoring TAA and TAG, the χ^2 for these observed and expected values is 23.0. If TAA and TAG are assigned to specific amino acids, only three of the 20 possible assignments result in lower χ^2 values: Glu ($\chi^2 = 19.9$), Gly (18.8) and Gln (16.5). Therefore, the data show that the best fit is obtained if glutamine is encoded by TAA and TAG. Normal codons for glutamine are CAA and CAG, both of which are found in our sequences. The data of Caron and Meyer[8] show that the level of Glu + Gln is low. Helftenbein[9] reports a TAA that appears to specify glutamine in several α-tubulin genes in *Stylonychia*, and Horowitz and Gorovsky[10] have found a TAA specifying glutamine in a histone gene in *Tetrahymena*. Perhaps TAA specifies glutamine in all ciliated protozoa. Finally, the total of 345 codons in reading frame 1 includes 8 TAA, 3 TAG and 0 TGA, suggesting that UGA alone is used as a translational stop by *Paramecium*.

The use of UAA and UAG codons by ciliates should make their mRNAs poor templates for *in vitro* protein synthesis in heterologous systems, indeed numerous workers have found this to be the case [2,11-13]. Meyer *et al.* have concluded recently that the primary structure of the mRNAs from *Paramecium* is at fault[14].

We conclude that UAA and UAG do not represent stop codons in *Paramecium*; the only other deviations from the 'universal' genetic code have been found in mitochondria.

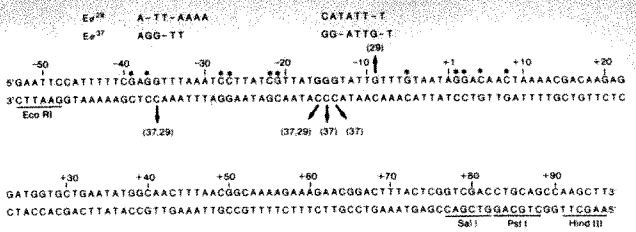

Fig. 1 Structure of the *ctc* promoter region, showing the nucleotide sequence of the *ctc* promoter region which was cloned into M13 mp9 and then recloned into pUC8. Transcription proceeds from left to right, with the lower strand representing the transcribed strand. The start point of transcription is indicated as nucleotide +1. Asterisks represent the positions at which base substitutions (transitions) have little effect on the utilization of this promoter by $E\sigma^{37}$ (ref. 6) or $E\sigma^{29}$. The arrows indicate those positions at which single base transitions more dramatically affect the utilization of the promoter by $E\sigma^{37}$ or $E\sigma^{29}$ as indicated (arrows pointing down indicate a decrease in utilization and the arrow pointing up indicates an increase in utilization). The nucleotide sequences shown above the *ctc* promoter sequence are the sequences (non-transcribed strand shown) which are conserved in promoters recognized by $E\sigma^{37}$ or $E\sigma^{29}$ as indicated[6,8].

Utilization of one promoter by two forms of RNA polymerase from *Bacillus subtilis*

Kathleen M. Tatti & Charles P. Moran Jr*

Department of Microbiology and Immunology,
Emory University School of Medicine, Atlanta, Georgia 30322, USA

***Bacillus subtilis* possesses several forms of RNA polymerase, each differing in its σ subunit and its specificity of promoter recognition[1,2]. The sequential appearance of σ subunits, which change the promoter recognition specificity of RNA polymerase, may have a key role in controlling the temporal pattern of gene expression required for endospore development in *B. subtilis*[3]. Several genes that are expressed over relatively long periods of time during the developmental cycle are transcribed by more than one form of RNA polymerase, which initiate transcription from either tandem or overlapping promoters[2,4]. The promoter region for the *ctc* gene is interesting because transcription is initiated at or near the same position by both σ^{37} RNA polymerase ($E\sigma^{37}$), a minor form in growing cells, and σ^{29} RNA polymerase ($E\sigma^{29}$), a form which appears ~2 h after the initiation of sproulation[5]. Here we report that several base substitutions in the *ctc* promoter differentially affect the utilization of the promoter by $E\sigma^{37}$ or $E\sigma^{29}$.**

We have reported previously the use of site-directed bisulphite mutagenesis to construct a series of single and multiple base substitutions in the *ctc* promoter[6]. For this purpose, we cloned a 130-base pair (bp) DNA fragment containing the *ctc* promoter into the *Escherichia coli* phage M13 mp9 to produce phage M13-31 (Fig. 1). After mutagenesis and transfection[6], the 143-bp *Eco*RI/*Hin*dIII DNA fragment containing the promoter region was excised from each phage DNA and ligated between the *Eco*RI and *Hin*dIII restriction sites of plasmid pUC8 (ref. 7). The structure of each plasmid was confirmed by determining the nucleotide sequence of the *Eco*RI/*Hin*dIII DNA fragment (Table 1).

To test the function of the mutant promoters, we assayed their ability to direct transcription by $E\sigma^{29}$ and $E\sigma^{37}$ in an *in vitro* run-off assay. Template DNA was prepared by cutting the plasmid DNA at the unique *Hin*dIII restriction site 95 bp downstream from the startpoint of transcription (Fig. 1). $E\sigma^{37}$ or $E\sigma^{29}$ RNA polymerase was incubated with an excess of the cut template DNA and the discrete run-off transcripts visualized by autoradiography after electrophoresis in a polyacrylamide/urea gel. Figure 2 shows the transcripts generated from a series of mutant promoters with single base substitutions at positions occupied by guanine in the non-transcribed stand of the wild-type promoter. As we had shown previously using phage replicative-form DNA as template[6], the single base pair substitutions causing the greatest reduction in promoter utilization by $E\sigma^{37}$ were at positions −36, −16, −15 and −14 (Fig. 2, lanes *d*, *f*, *g*, *h*, respectively, and Table 1).

Each of the cut templates was also transcribed by an equal amount of $E\sigma^{29}$ in reactions that otherwise were identical to the $E\sigma^{37}$ transcriptions. Transcription of the wild-type template by $E\sigma^{29}$ results in a 95-base transcript which co-migrates during electrophoresis in a high-resolution nucleotide sequencing gel with the 95-base transcript generated by $E\sigma^{37}$ (K.M.T. and C.P.M. Jr, unpublished data). We also observed some non-specific transcription products that migrate more slowly than the 95-base run-off transcript (Fig. 2, lane *k*). The intensity of this nonspecific background did not correlate with the intensity of the run-off transcript (Fig. 3, compare lanes *f* and *g*).

Transcription of this series of cut templates by $E\sigma^{29}$ revealed that the base substitution at position −15, which greatly reduced transcription by $E\sigma^{37}$, had little effect on transcription by $E\sigma^{29}$ (Fig. 2, lane *q*). This template was an aliquot of the same cut template used for transcription by $E\sigma^{37}$ (Fig. 2, lane *g*), thereby providing additional evidence that the inefficiency of transcription of this template by $E\sigma^{37}$ was not caused by the quality of the template preparation (also see mixing experiments in ref. 6). The base substitution at position −9 had little or no effect on transcription by $E\sigma^{37}$, but we observed a slight enhancement of transcription from this template by $E\sigma^{29}$ (Fig. 2, lane *s*).

Promoters containing single base substitutions at positions −36 or −16 directed less transcription by $E\sigma^{29}$ (Fig. 2, lanes *n*, *p*; Table 1). Mixing experiments were used to eliminate the possibility that these template preparations contain an inhibitor of $E\sigma^{29}$. When *Pst*I-cut wild-type template was mixed with each *Hin*dIII-cut mutant template in pre-binding transcription reactions with $E\sigma^{29}$, the mutant templates did not inhibit transcription from the wild-type template (data not shown).

We have also tested promoters containing multiple base substitutions in similar pre-binding transcription reactions (Table

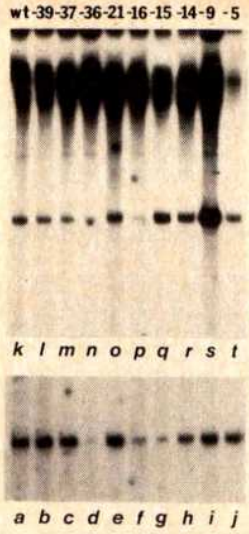

Fig. 2 Run-off transcripts from mutant promoters. $E\sigma^{37}$ from *B. subtilis* JH646 (*spoOA*) was purified as described elsewhere[6] and was shown to contain no contaiminating $E\sigma^{32}$ or $E\sigma^{29}$ by *in vitro* transcription of plasmids pCB1291 and pMB9, which contain promoters utilized uniquely by $E\sigma^{32}$ and $E\sigma^{29}$, respectively[2,5]. The results were reproduced with $E\sigma^{37}$ isolated from *B. subtilis* (SMY). $E\sigma^{29}$ was purified on two different occasions from *B. subtilis* (SMY) by gradient elution from DNA-cellulose as described by Haldenwang *et al.*[5] and shown to be free of contaminating $E\sigma^{32}$ and $E\sigma^{37}$ by transcription of pCB1291, which contains promoters used uniquely by $E\sigma^{37}$ and $E\sigma^{32}$ (ref. 2). We have not excluded the possibility that in addition to their sigma subunits, these holoenzymes differ by modifications that cannot be detected by electrophoresis in SDS-polyacrylamide gels. Addition of a mixture of $E\sigma^{37}$ and $E\sigma^{29}$ to a mutant template has the expected additive effect; therefore, the differential effects are not due to impurities in the polymerase preparations. RNA was transcribed as described previously[6] by $E\sigma^{37}$ (lanes *a–j*) or $E\sigma^{29}$ (lanes *k–t*) from the following templates that had been cleaved at the *Hin*dIII site 95 bp downstream from the *ctc* promoter: pUC8-31, lanes *a, k*; pUC8-39, lanes *b, l*; pUC8-37, lanes *c, m*; pUC8-36, lanes *d, n*; pUC8-21, lanes *e, o*; pUC8-16, lanes *f, p*; pUC8-15, lanes *g, q*; pUC8-14, lanes *h, r*; pUC8-9, lanes *i, s*; pUC8-5, lanes *j, t*. The number above each lane refers to the position of the base substitution in the *ctc* promoter region of the template. The asterisks denote the position of the 95-base run-off transcript generated by $E\sigma^{37}$ or $E\sigma^{29}$ as indicated. The transcripts were visualized by autoradiography after electrophoresis in a 7 M urea/9% (w/v) polyacryalamide gel.

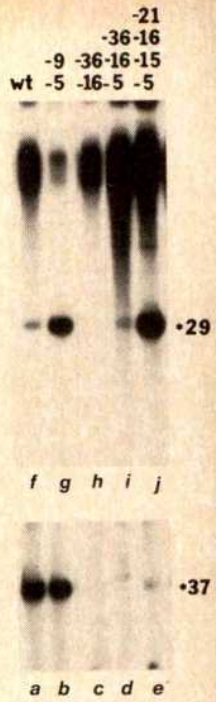

Fig. 3 Run-off transcripts from mutant promoters. RNA was transcribed with $E\sigma^{37}$ (lanes *a–e*) or $E\sigma^{29}$ (lanes *f–j*) from the following plasmid templates that had been cleaved at the *Hin*dIII site 95 bp downstream from the *ctc* promoter: pUC8-31, lanes *a, f*; pUC8-313, lanes *b, g*; pUC8-3111, lanes *c, h*; pUC8-3118, lanes *d, i*; pUC8-3146, lanes *e, j*. The number above each lane refers to the positions of the base substitutions in the *ctc* promoter region of the template (see Table 1). The asterisks denote the position of the 95-base run-off transcripts generated by $E\sigma^{37}$ or $E\sigma^{29}$ as indicated. The transcripts were visualized by autoradiography after electrophoresis in a 7 M urea/9% (w/v) polyacrylamide gel.

1, Fig. 3). Promoter 3146, containing base substitutions at positions −21, −16, −15 and −5, directed little or no transcription by $E\sigma^{37}$ (Fig. 3, lane *e*), but directed transcription by $E\sigma^{29}$ more efficiently than did the wild-type *ctc* promoter (Fig. 3, lane *j*). Promoter 313, with transitions at positions −9 and −5, was also used more efficiently by $E\sigma^{29}$ than the wild-type *ctc* promoter (Fig. 3, lane *g*). Two promoters (3111 and 3118), containing multiple base substitutions including positions −36 and −16, were used less efficiently than the wild-type *ctc* promoter by both $E\sigma^{37}$ and $E\sigma^{29}$ (Fig. 3, lanes *c, d, h, i*).

Although $E\sigma^{37}$ and $E\sigma^{29}$ use the *ctc* promoter to initiate transcription at or near the same position[5,8], the present results support a model in which these two forms of RNA polymerase utilize the *ctc* promoter by interacting with different nucleotides within the *ctc* promoter region. The most dramatic demonstration that a single base pair within the promoter is critical for utilization by one form of RNA polymerase, but not the other, is the base substitution at position −15. This base substitution severely limits utilization of the promoter by $E\sigma^{37}$, but not $E\sigma^{29}$. Promoter 3146, which has multiple base substitutions, also demonstrates the differential effects of base substitutions on promoter utilization by $E\sigma^{37}$ and $E\sigma^{29}$.

Can we identify those sequences that signal recognition by each type of RNA polymerase? We have proposed that $E\sigma^{37}$

Table 1 Activity of mutant *ctc* promoters

Plasmid	Positions of base substitutions (transitions)	Transcription relative to wild-type *ctc* promoter (%)

recognizes its cognate promoters by interaction with the nucleotides near the −10 region (10 bp upstream from the startpoint of transcription) and the −35 region (35 bp upstream from the startpoint of transcription) of these promoters[6]. The nucleotide sequence GG-ATTG-T and AGG-TT (non-transcribed strand shown) at the −10 region and −35 region, respectively, are conserved among promoters recognized by $E\sigma^{37}$ (see Fig. 1), and methylation protection experiments reveal that these sequences are in close contact with bound $E\sigma^{37}$ (ref. 9). Finally, the base substitutions that severely affect utilization of the *ctc* promoter by $E\sigma^{37}$ alter bases at positions −36, −16, −15 and −14 (ref. 6).

The sequences CATATT-T and A-TT-AAAA (non-transcribed strand shown) at the −10 and −35 region, respectively, are highly conserved among the four promoters known to be used by $E\sigma^{29}$ (Fig. 1)[8]. The base substitutions affecting the utilization of the *ctc* promoter by $E\sigma^{29}$ (positions −36, −16 and −9) do not replace conserved nucleotides, but may act by affecting $E\sigma^{29}$ contacts with neighbouring conserved nucleotides.

A base substitution at position −36 or −16 decreases utilization of the *ctc* promoter by both $E\sigma^{29}$ and $E\sigma^{37}$, whereas other mutations differentially affect utilization of the promoter. We therefore conclude that these two RNA polymerases utilize the *ctc* promoter by interacting with two different but overlapping sets of nucleotides. According to this model, the *ctc* promoter region is a composite of two overlapping promoters, one set of nucleotides signalling recognition by $E\sigma^{37}$ and an intercalating set signalling recognition by $E\sigma^{29}$.

Control of germ cell nuclear behaviour at fertilization by *Tetrahymena* intermediate filament protein

Osamu Numata*, Toshiro Sugai† & Yoshio Watanabe*

† Department of Biology, Ibaraki University, Mito, Ibaraki 310, Japan

Intermediate filament protein [relative molecular mass (M_r) 49,000 (49K)] from the ciliated protozoan *Tetrahymena* has been shown to resemble intermediate filament proteins from mammalian cells in several respects[1], and to have a possible role in the oral morphogenesis preceding binary fission in *Tetrahymena*[2]. Here, based on immunofluorescence localization of the 49K protein in *Tetrahymena* during the early stages of conjugation, we suggest that the protein is involved in some nuclear events[3–5], such as the production of four haploid nuclei by prezygotic divisions (meiosis), selection of one of the four meiotic products, formation of the gametic pronucleus by the mitotic division of the selected meiotic product, transfer of the gametic pronucleus across a cell–cell junction, and zygote formation by pronuclear fusion.

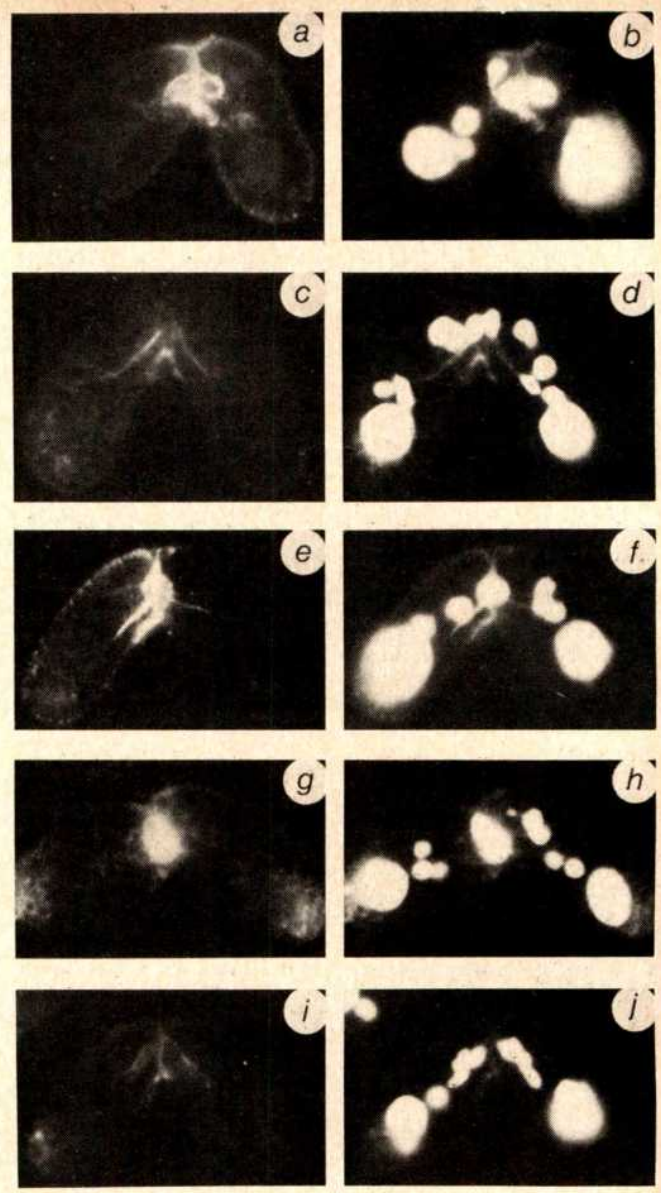

Fig. 1 Immunofluorescence localization of 49K protein in relation to the nuclear events of fertilization in *Tetrahymena*. The conjugation of *Tetrahymena thermophila* (BII and BIII) was synchronized by using a modification of the method of Sugai and Hiwatashi[14]. Detergent-extracted cells with conjugating pairs were prepared as described by Goodenough[6] and air-dried on slides. These unfixed cells were subjected to indirect immunofluorescence staining with anti-49K protein antiserum (diluted 1:160 in phosphate-buffered saline, PBS) and rhodamine-conjugated goat anti-rabbit IgG (diluted 1:200 in PBS; Miles). The macro- and micronuclei were stained with 0.5 μg ml^{-1} DAPI. *a, c, e, g, i*, Fluorescence photomicrographs of extracted cells stained with anti-49K protein antiserum. *b, d, f, h, j*, Extracted cells stained with anti-49K protein antiserum and DAPI (double exposure). *a* and *b* were taken at 5.75 h, *c* and *d* at 6.5 h, *e* and *f* at 7.0 h, *g* and *h* at 7.25 h, and *i* and *j* at 7.5 h after mixing of complementary mating-type cells. For an explanation of the dotted fluorescence in the cortical regions, see ref. 2.

By using immunofluorescence, we localized the 49K protein in *Tetrahymena* cells at various stages of synchronous conjugation, using an antiserum against 49K protein. Immune blotting experiments have shown that the antiserum is highly specific for 49K protein[2]. Using the monospecific antiserum, we observed that after pair formation in *Tetrahymena*, immunofluorescence appeared in some filamentous structures and/or in an eyeglass-like structure around the cell–cell junction. We were interested

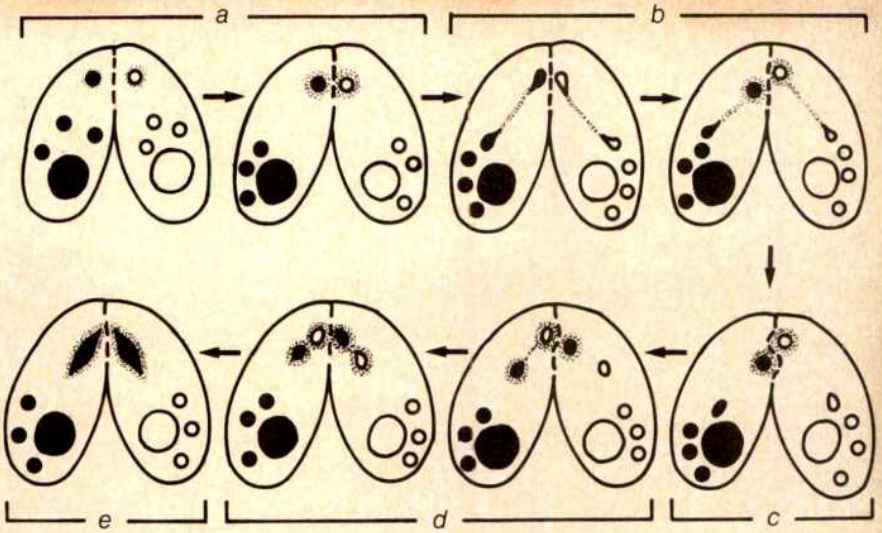

Fig. 2 Schematic diagram of the change in the distribution of 49K protein at conjugation in *Tetrahymena*: *a*–*e* represent the stages of conjugation. *a*, Only one of four meiotic products approaches the junction of the two cells (see Fig. 1*a*, *b*). *b*, This product divides mitotically to yield the migratory and stationary pronuclei (see Fig. 1*c*–*f*). *c*, The migratory pronucleus moves across the cell junction (refer to Fig. 1*g*, *h*). *d*, The stationary pronucleus moves towards the incoming migratory pronucleus (Fig. 1*i*, *j*). *e*, Two gametic pronuclei fuse to generate a fertilization nucleus. The fine black dots show the localization of the 49K protein.

in these fluorescence patterns because they seemed to reflect the behaviour of germ cell nuclei at conjugation. Because the behaviour of the nucleus can be considered as a form of cell motility and since the 49K protein is thought to constitute the cytoskeleton responsible for cell motility, immunofluorescence staining was performed on detergent-extracted cells prepared by the method of Goodenough[6]. The fluorescence patterns of these extracted cells, taken from various stages of conjugation, were essentially the same as those of whole cells, a finding that suggests strongly the importance of cytoskeletal 49K protein. Furthermore, cytoskeletal 49K protein and germ cell nuclei are located close to each other, as revealed by extracted cells double-stained with rhodamine-conjugated antibody and DAPI(4′,6-diamidino-2-phenylindole dihydrochloride) (see Fig. 1).

Next, we determined the sequence of the stages showing the various immunofluorescence patterns by measuring the frequency of occurrence of each stage (data not shown); fluorescence in the functional oral apparatus disappeared 2 h after mixing of the complementary mating-type cells. The first and second prezygotic divisions (meiosis) occurred ~4 h and 4.5 h, respectively, after mixing, and resulted in the production of four haploid nuclei. At a later stage of the second prezygotic division, filamentous structures linking the separating nuclei showed transitory fluorescence (results to be published elsewhere). At 5.75 h after mixing, one of the four meiotic products had approached the junction of the two cells; the periphery of this product fluoresced strongly, whereas the peripheries of the other three products showed no fluorescence (Fig. 1*a*, *b*). The former is known to become the functional germ nucleus and the latter three the relic nuclei. At 6.5 h, only the functionally active nucleus divided mitotically to give rise to the migratory and stationary gametic pronuclei. At the separation stage of mitosis, a filamentous structure linking the two pronuclei fluoresced conspicuously (Fig. 1*c*, *d*); immediately after this, the periphery of the presumptive migratory pronucleus fluoresced again and the filament between the pronuclei began to show diminished fluorescence (Fig. 1*e*, *f*). At 7.0 h after mixing, the migratory pronucleus was about to move across the cell junction; intense fluorescence was observed around the migratory pronucleus, whereas fluorescence from the filamentous structure disappeared (Fig. 1*g*, *h*). At 7.25 h, corresponding to the stage just after pronuclear exchange but before pronuclear fusion, a filamentous structure linking the incoming migratory nucleus and the stationary nucleus fluoresced again (Fig. 1*i*, *j*) and the peripheries of the gametic pronuclei also fluoresced. At this stage, we found a remarkable difference between the stationary pronucleus and the relic nuclei in terms of immunofluorescence. The filamentous structure shortened as the pre-fusion process progressed. At 7.5 h after mixing, the gametic pronuclei fused to form the fertilization nucleus.

It has long been thought that in *Tetrahymena* and *Paramecium*, the determination, differentiation and behaviour of germ nuclei during conjugation result from localized differences in the cytoplasm surrounding them[3,7–10], but there is no evidence of such cytoplasmic controlling factors. The present study provides some important clues for solving this problem: *Tetrahymena* intermediate filament protein (49K protein) is presumably involved in the germ nuclear events (see Fig. 2, which summarizes the results of the present experiments schematically). From the immunofluorescence localization of 49K protein, we believe that the protein is involved to some extent in: (1) the selection of one functional nucleus from four haploid nuclei generated by meiosis (Fig. 2*a*); (2) the division of the functional nucleus to generate migratory and stationary pronuclei (Fig. 2*b*); (3) the determination of the migratory pronucleus (Fig. 2*b*); (4) the migratory pronuclear exchange (Fig. 2*c*); (5) the selection of two gametic pronuclei from five nuclei (including three relic nuclei) to form the fertilization nucleus (Fig. 2*d*); and (6) the fusion of gametic pronuclei (Fig. 2*d*, *e*).

It is known that gametic pronuclear exchange is blocked by inhibitors of microtubule assembly[11]. Recently, Orias *et al.*[12] showed that each migratory pronucleus is surrounded by a microtubular meshwork. We speculate that, as well as the microtubular meshwork, the cytoskeletal 49K protein has a crucial role in the transfer of gametic pronuclei across the cell junction, and that 49K protein interacts with the microtubules. As the microtubules are observed at the time of separation of the germ pronuclei (T. Yasuda, personal communication), the 49K protein may also be present owing to its association with the microtubules. Such an association does not, however, hold true for all the cases in which microtubules are present in large numbers: ciliary axonemes, most parts of the oral apparatus, cortical microtubular bands, and the micronucleus at the crescent stage of meiotic prophase[13] showed no anti-49K protein immunofluorescence. Thus, we conclude that *Tetrahymena* intermediate filament protein may have crucial roles in fertilization either alone or in association with some microtubules having specialized functions.

Reversible cyclic AMP-dependent change in distribution of myosin thick filaments in *Dictyostelium*

Shigehiko Yumura & Yoshio Fukui

Department of Biology, Faculty of Science, Osaka University, Toyonaka, Osaka, 560 Japan

Myosin is thought to act as a major mechanochemical transducer in non-muscle cell motility[1], but the *in situ* organization of the molecules has not yet been determined. Here we report the localization of myosin 'rods', analogous to the thick filaments of muscle, by ameliorated immunofluorescence and demonstrate the dynamic translocation of these rods in response to exogenously added cyclic AMP, which is a chemoattractant for *Dictyostelium* amoebae. On addition of cyclic AMP, we observed instantaneous shedding of the endoplasmic myosin followed by an increase in cortical rods, the original distribution being recovered in a few minutes. We conclude that myosin filaments mediate *Dictyostelium* cell movement, probably by an assembly/disassembly cycle of the molecules in response to a chemotactic stimulus.

We established a hybridoma that produces a monoclonal antibody (IgG) against *Dictyostelium* myosin. This antibody recognizes myosin heavy chain, using immunoblotting techniques[2]. Immunogold staining of purified *Dictyostelium* myosin shows that the antibody is reactive to reconstituted myosin thick filaments (Fig. 1*a*, *b*). We have modified our 'agar-overlay' immunofluorescence technique, which enables us to localize *Dictyostelium* actin, myosin and tubulin[2,3]. Our improved fixation protocol allows the specific visualization of fluorescent rod-like shapes (Fig. 1*c*). The rods are uniform in size (0.1–0.2 μm wide, 0.7 μm long) and identical to those found with immunofluorescent staining of reconstituted thick filaments of *Dictyostelium* myosin (Fig. 1*d*). The presumptive myosin rods are localized at the cortical region of vegetative cells, shown by fluorescence micrographs taken at several focal planes (Fig. 2*a*–*d*).

We believe that our fixation procedure reflects the *in situ* form of the molecules as: (1) the samples were fixed instantaneously in cold methanol-containing formalin and (2) once fixed, the rods did not dissolve even when the phosphate-buffered saline (PBS) was replaced with myosin solubilizing solution (containing 0.6 M KCl). We found no thick filaments in transmission electron micrographs of thin sections of cells prepared for the immunofluorescence experiments. We next investigated the possible disruption of the thick filaments by our fixation method (Table 1). Fixation with 0.1% OsO_4 for 10 min at 4 °C destroyed the rod-like structures, leaving only weak dot-like fluorescence. Thus, non-muscle myosin thick filaments are susceptible to chemical fixation, which may be the reason for the controversy about their existence in non-muscle cells[4,5].

A vegetative cell undergoes cytokinesis every 3 h. At this stage, the cortical fluorescence mostly disappears except in part of the cleavage furrow. The myosin rods are aligned in parallel with each other, forming a circular and peripheral ring-shaped fluorescence (Fig. 2*e*–*h*). This suggests the presence of a contractile ring[6] of microfilaments at the constricting portion of the dividing cells.

When the amoebae start development, their motile activity increases. During the initial 2 h of development, myosin rods increase in number and appear in the endoplasm side by side in the cortex (Figs 2*k*; 3*a*, *c*). In polarized cells undergoing

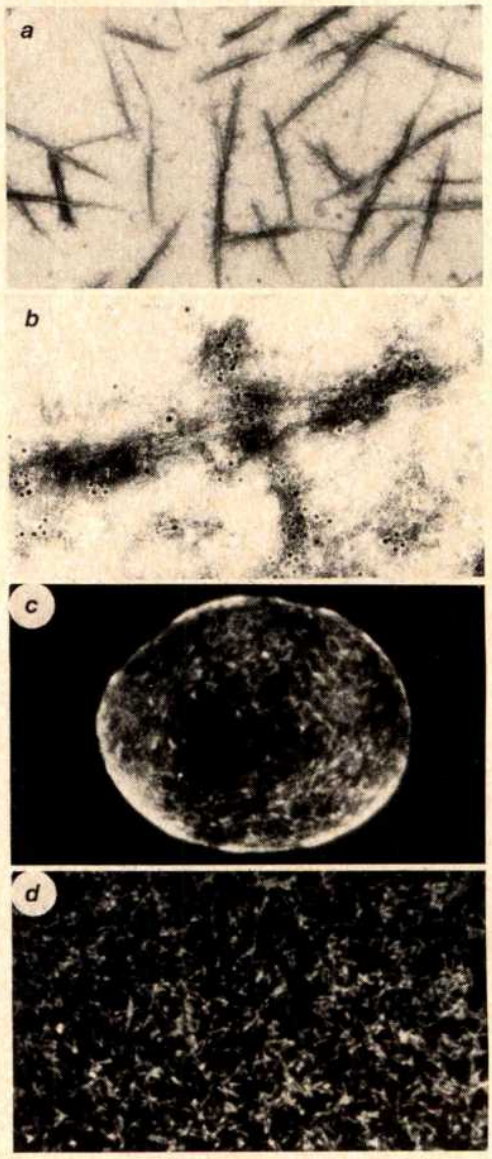

Fig. 1 Electron and immunofluorescence micrographs of reconstituted thick filaments of *Dictyostelium* myosin and *in situ* localization of presumptive thick filaments by agar-overlay immunofluorescence[2]. *a*, Negative staining of reconstituted thick filaments, ×29,600. Assembled myosin molecules form spindle-shaped bipolar filaments. *b*, Immunogold staining of purified myosin filaments, ×118,400. *c*, Immunofluorescence micrograph of a *Dictyostelium* cell prepared by agar-overlay immunofluorescence, ×1,739. *d*, Immunofluorescent staining of purified myosin thick filaments, ×1,739.

Methods. *Dictyostelium* myosin was purified by the method of Mockrin and Spudich[15] and the thick filaments formed by dialysis against a low salt buffer (50 mM KCl, 1 mM EDTA, 10 mM $MgCl_2$, 1 mM dithiothreitol (DTT), 10 mM imidazole, *p*H 6.5). *b*, Reconstituted thick filaments were placed on a poly-L-lysine-coated grid, incubated with our myosin antibody and stained with colloidal gold-conjugated second antibody (GAM-G5, Janssen). The monoclonal anti-*Dictyostelium* myosin binds to the thick filaments. *c*, Cells were placed on a coverslip, overlaid with a thin agarose sheet and immediately immersed into methanol containing 1% formalin at −15 °C, then fixed for 5 min. After washing with PBS, the cells were incubated with the anti-*Dictyostelium* myosin for 30 min and then fluorescein isothiocyanate (FITC)-labelled goat anti-mouse IgG (Miles-Yeda) for 30 min at 37 °C. *d*, Reconstituted thick filaments were placed on a poly-L-lysine-coated coverslip, incubated with our antibody and stained with FITC-labelled second antibody.

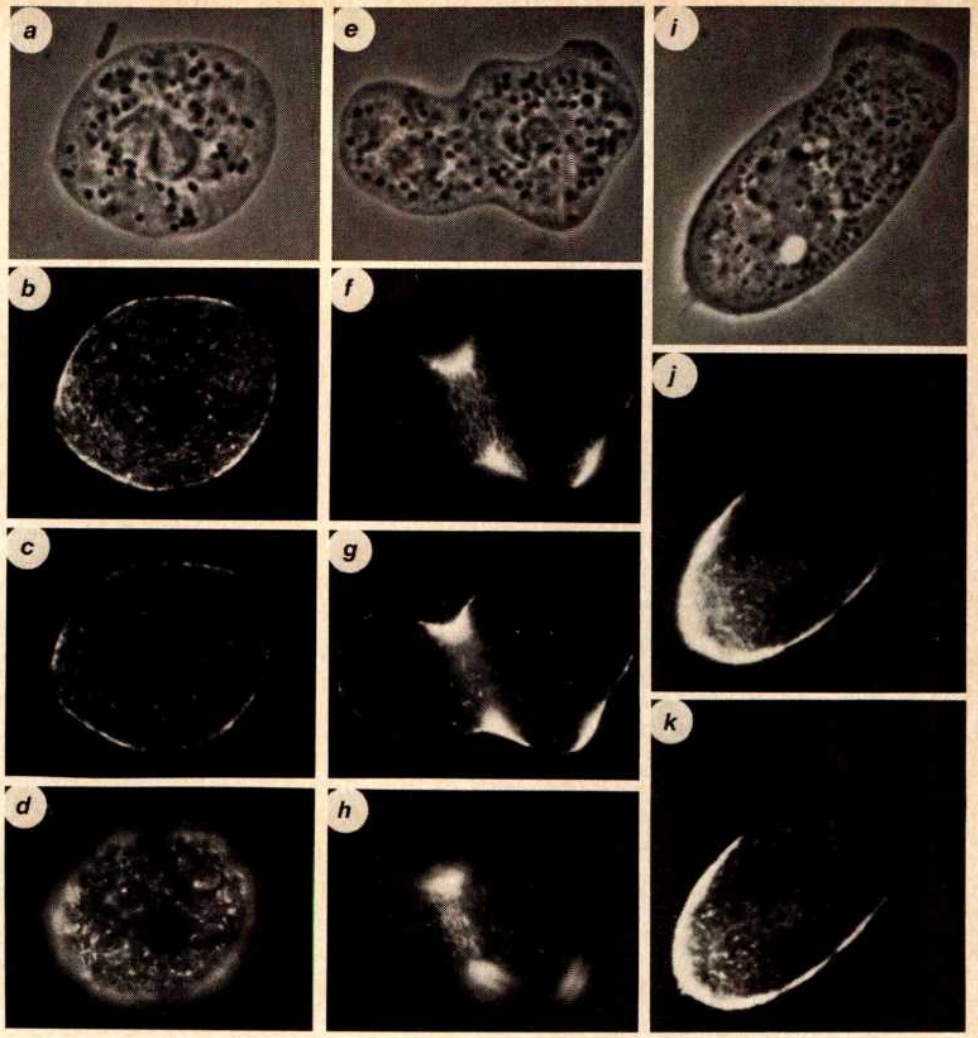

Fig. 2 Specific distribution of myosin rods in *Dictyostelium discoideum* amoebae shown by agar-overlay immunofluorescence[2]. *a–d*, Phase-contrast (*a*) and fluorescence (*b–d*) micrographs showing specific localization of myosin rods at the cortical region of a vegetative cell. ×1,572. Immunofluorescence micrographs taken at three different focal planes of the cell verified that the rods were localized only at the upper (*b*) and lower (*d*) cortices. Note that the rods are aligned in parallel with the cortex. *e–h*, Phase-contrast (*e*) and fluorescence (*f–h*) micrographs showing the distribution of myosin rods aligned in parallel forming a contractile-ring-like array. ×1,443. *f–h*, Immunofluorescence micrographs taken at three different focal planes of the cell performing cytokinesis. The micrographs taken at the upper (*f*), middle (*g*), or lower (*h*) plane confirmed that the rods were arranged in a peripheral circular ring at the cleavage furrow. The number of rods at the cell cortex other than the constricting portion have decreased. *i–k*, Phase-contrast (*i*) and immunofluorescence (*j*, *k*) micrographs showing that the myosin rods are localized specifically in the posterior cortex of a polarized cell and form linear alignments. *j*, *k*, Immunofluorescence micrographs taken at the upper (*j*) or middle (*k*) plane demonstrate that the rods are localized in the endoplasm (*k*) as well as in the cortex (*j*) at this stage. ×1,572.

Table 1 Effects of chemical fixation on the disruption of *in situ* myosin rods of *Dictyostelium*

Glutaraldehyde %	OsO_4 %	Myosin rods
0	0	+
1	0	?
2	0	−
0	0.01	+
0	0.1	??
1	0.01	−
2	0.1	−

A stock solution of glutaraldehyde (25%; Electron Microscopy Science) was diluted with PBS (138 mM NaCl, 2.7 mM KCl, 8 mM phosphate buffer, *p*H 7.2). The sample was fixed for 30 min at 25 °C. Stock solution of OsO_4 (8%; Merck) was diluted with PBS and the sample fixed for 10 min at 4 °C. The degree of fluorescent staining of myosin rods was judged as follows: −, no specific rod-like fluorescence detectable, partially because of autofluorescence from glutaraldehyde; +, normal rod-like fluorescence; ?, faint rod-like fluorescence identified against the bright autofluorescence; ??, fluorescent dots were seen instead of rod-like shapes.

directed locomotion with the anterior pseudopod, we find that the rods accumulate in the posterior cortex. Occasionally, some near alignments of the rods occur just beneath the cortex (Fig. *i–k*). This evidence supports the suggestion that the force for moeboid movement is generated by contraction of the posterior cortex[2,7].

The assembly of *Dictyostelium* myosin is thought to be regulated by heavy-chain phosphorylation; dephosphorylation would cause the monomeric myosin to form thick filaments with much actin-activated ATPase[8], in contrast to the situation in mammalian myosins[9,10]. Malchow *et al.*[11] found that the addition of the chemoattractant cyclic AMP to the aggregation-competent cells induced the rapid and transient phosphorylation/dephosphorylation cycle of myosin heavy chains. Do thick filaments perform cyclic changes of disassembly/assembly in response to the cyclic AMP signal? Here, we find that the myosin rods disappear from the endoplasm and accumulate in the ectoplasm within 2 min of treatment with 10^{-6} M cyclic AMP at 5 °C. After 1 min, the rods have redistributed throughout the endoplasm (Fig. 3*a–c*). This change in distribution is dramatic and occurs in almost all of the observed cells within 1 min after the addition of cyclic AMP at 11 °C; it is too fast to follow at 23 °C.

If cyclic AMP is applied locally, the cell extends a pseudopod in the direction of the signal within several seconds[12]. Our results described here suggest that translocation of the endoplasmic myosin rods is coincident with this response to a chemotactic stimulus. As the accumulation of rods in the cell cortex is transient, we asked whether a cell without these endoplasmic rods could contract. We prepared Triton-insoluble ghosts of cells with endoplasmic rods depleted by treatment with cyclic AMP and examined their contractility in response to ATP. SDS-gel electrophoresis shows that the ghosts are composed mainly of actin and myosin, comprising up to 25% and 50% of the total cellular proteins (Fig. 3*f*). When 1 mM ATP is added to the ghosts, the cortex contracts in a few seconds (Fig. 3*d*, *e*). This suggests that the cortical myosin rods are organized in such a way to generate the force required for amoeboid movement.

The myosin rods described here are much larger than found normally in non-muscle cells[4]. We believe that the rod-shaped

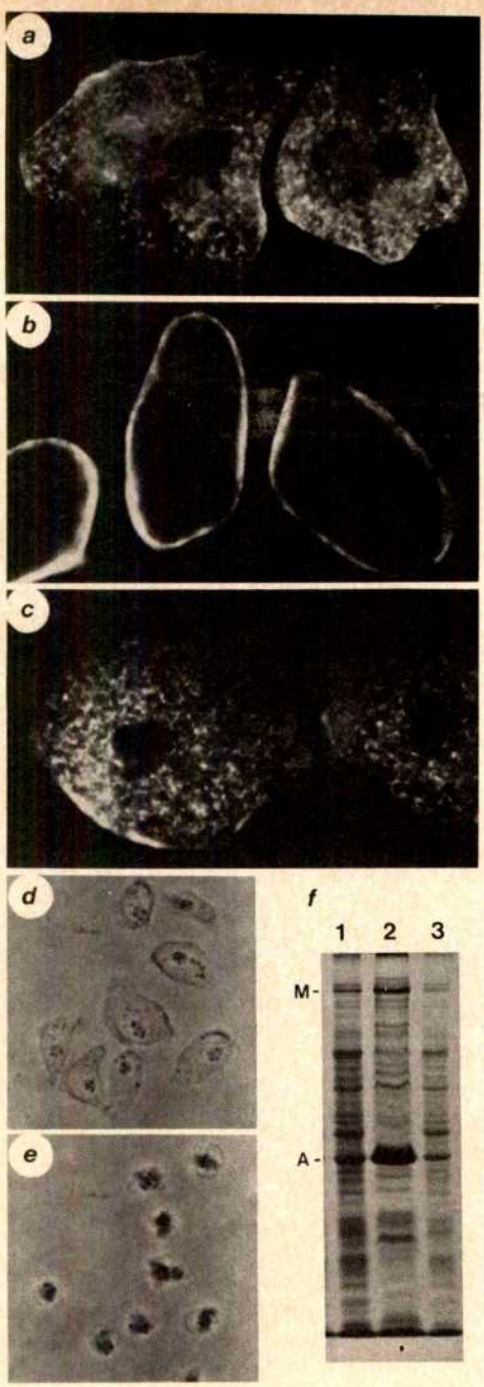

Fig. 3 Changes in the distribution of myosin rods in response to exogenously added cyclic AMP and the contractility of the cell cortex. A 10^{-6} M cyclic AMP solution in PBS buffer (15 mM, *p*H 6.5) was added to aggregation-competent cells overlaid with a thin agarose sheet at 5 °C. After the indicated time, the cells were plunged into −15 °C methanol containing 1% formalin and prepared for the agar-overlay immunofluorescence[2]. *a*, Control cell; *b*, 2 min; *c*, 3 min after cyclic AMP application ×1,350. Note the disappearance of the endoplasmic rods and their accumulation at the cortex in *b* and their reappearance in *c*. The same batch of cells was overlaid with a thin agarose sheet and treated with 10^{-6} M cyclic AMP at 5 °C. After 2 min, when the endoplasmic rods disappeared as shown in *b*, the cells were permeabilized with P buffer (10 mM PIPES, 50 mM KCl, 1 mM $MgCl_2$, 10 mM EGTA, 1 mM DTT, 0.2 mM phenylmethylsulphonyl fluoride, *p*H 7.6) containing 0.5% Triton X-100 for 10 min at 0 °C, then extracted with P buffer for 5 min. Phase-contrast micrograph (*d*) shows that the Triton-insoluble ghosts contain the cell cortex, nucleus and some cytoplasmic debris. *d*, *e*, Contracted ghosts a few seconds after application of P buffer containing 1 mM ATP. ×417. For SDS-polyacrylamide gel electrophoresis, a suspension of aggregation-competent cells was treated with 10^{-6} M cyclic AMP for 2 min at 5 °C, then permeabilized with P buffer containing 0.5% Triton X-100 for 10 min on ice. After 5 min centrifugation at 10,000 r.p.m. the pellet and supernatant were separated and boiled for a few minutes in SDS sample buffer (0.25 M Tris-HCl, 4% SDS, 20% glycerol, 10% 2-mercaptoethanol, *p*H 6.8). The whole-cell lysate was prepared by solubilizing the cells with pre-warmed SDS sample buffer. SDS-polyacrylamide gel electrophoresis was performed[16] and protein quantity was estimated using a Gelman Model DCD-16 densitometer. *f*, Lane 1, whole-cell lysate (100 μg); lane 2, Triton-insoluble proteins (85 μg); lane 3, Triton-soluble proteins (50 μg); A, actin; M, myosin heavy chain.

fluorescence represents *in situ* myosin thick filaments, partly because of their immunological and morphological characteristics, and partly because of their specific localization in the cleavage furrow, their linear alignment and the dynamic cycle of the possible disassembly/assembly in response to cyclic AMP. The rods observed by immunofluorescence seem larger than those observed by negative stain (Fig. 1*a*, *d*). The size is probably amplified both by the antibody binding and by the fluorescence reflecting fuzzy, unwound projections of the molecules radiating from the rods.

An average cell should contain $\sim 3.8 \times 10^{-10}$ mg myosin, assuming that each cell has 7.5×10^{-8} mg protein and that myosin is 0.5% of the total cell protein[13], equivalent to 5×10^5 myosin molecules. Assuming that ~75% of the molecules formed thick filaments (suggested by *in vitro* phosphorylation[8]) and that each thick filament is composed of 30 molecules, one cell should contain $\sim 1.3 \times 10^4$ thick filaments. This value is in agreement with the numbers counted here (Fig. 1*c*). We speculate that these rods are transferred by changes in the molecular assembly of myosin, possibly regulated by the phosphorylation/dephosphorylation of the molecules coupled with the chemotactic response. It is reasonable to suppose that the return of cortical rods to the endoplasm results from ATP-dependent contraction of cortical actomyosin. This idea is supported by the fact that *Dictyostelium* myosin bound to the membrane preparation is released from the cell cortex on treatment with Mg-ATP[14].

We conclude that *Dictyostelium* myosin forms thick filaments *in situ* and that translocation of these filaments occurs in coordination with the assembly/disassembly of the molecules in response to physiological changes.

† To whom all correspondence should be addressed

Histone H1^0 has a number of unusual properties that set it apart from other H1 subtypes (for review see ref. 1). For example, H1^0 synthesis is not strictly coupled to DNA synthesis[2], it is absent from the embryonic liver of mice (but present shortly after birth)[3,4] and its synthesis is hormone-dependent in some of the glands of adult rodents[3]. All the H1 subtypes differ in their DNA binding properties, and H1^0 has been shown to be preferentially associated with nuclease-resistant chromatin[5]. These features suggest that the H1^0 may have a role in developmental gene control. To investigate this further, we have fractionated the H1^0-containing nucleosomes of chromatin from adult mouse liver. We report here that the gene for α-fetoprotein, which is expressed in embryonic tissue but repressed soon after birth[6–9], is preferentially associated with the H1^0-containing nucleosomes. The related gene for albumin, which is expressed in both embryonic and adult tissues, is absent from the H1^0-containing nucleosome fraction. These results support a role for histone H1^0 in the control of gene expression.

Varshavsky[10] and Smith and Johns[11] have demonstrated that nucleosomes can be separated as a function of their H1 content by a non-denaturing polyacrylamide gel electrophoresis system[12]. We have adapted this technique for the preparation of H1^0-containing nucleosomes using a digest of adult mouse liver nuclei in which the amount of H1^0 relative to total H1 is 35%. As shown in Fig. 1, monomers representing 50% of the total DNA in the conditions of digestion can be resolved into four bands. To characterize the monomers further, the bands were excised from the gel and their protein content and DNA length analysed. The results are shown in Fig. 1 and summarized in Table 1.

Class 1 and 2 monomers contain no histone H1; class 3 monomers contain histone H1^0 only, with a slight contamination by H1-2 (<1%), while class 4 monomers contain the full complement of histone H1 (H1-1, H1-2, H1^0). The amount of H1^0 relative to total H1 is 20%, indicating that class 4 monomers contain ~20% of nucleosomes bearing H1^0 if one assumes one molecule of H1 per nucleosome.

The DNA length measurements show that class 1 monomers are actually core particles, while class 2, 3 and 4 monomers have the DNA length expected for nucleosomes, 166–204 base pairs. DNA from the various monomer fractions was purified as described in Fig. 1 legend and spotted in equal amounts on nitrocellulose filters. The filters were hybridized either with a probe for albumin gene (ALB) or with a probe for α-fetoprotein gene (AFP), that is, genes that are, respectively, expressed and not expressed in adult mouse liver.

The DNA of the nucleosome fraction containing only H1^0 (class 3 monomers) hybridizes strongly with the AFP probe but very weakly with the ALB probe (Fig. 2). In contrast, the DNA of class 1 and 4 monomers hybridizes strongly with the ALB probe but very weakly with the AFP probe (Fig. 2). The DNA purified from unfractionated nucleosomes hybridizes roughly equally with both probes. The fractionation procedure used in our study produces two populations of H1^0-containing nucleosomes that may reflect heterogeneity in H1^0 (ref. 13). The 20% of H1^0-containing nucleosomes in class 4 monomers do not hybridize to the AFP probe, which suggests that their functional properties differ from those of the H1^0-containing nucleosomes of class 3 monomers.

The present study shows that: (1) A coding sequence expressed in adult liver (ALB) is found in the fraction of class 4 monomers which contains the full complement of H1 histones. The results concerning the presence of H1 in active chromatin are still unclear, but our observation agrees with Berent and Sevall[14] and with Weintraub[15], who have shown that H1 is present in active chromatin. (2) Most of a coding sequence not expressed in the adult liver (AFP) is found in the fraction of monomers containing only H1^0, while an expressed coding sequence (ALB) is absent from this fraction but found in the

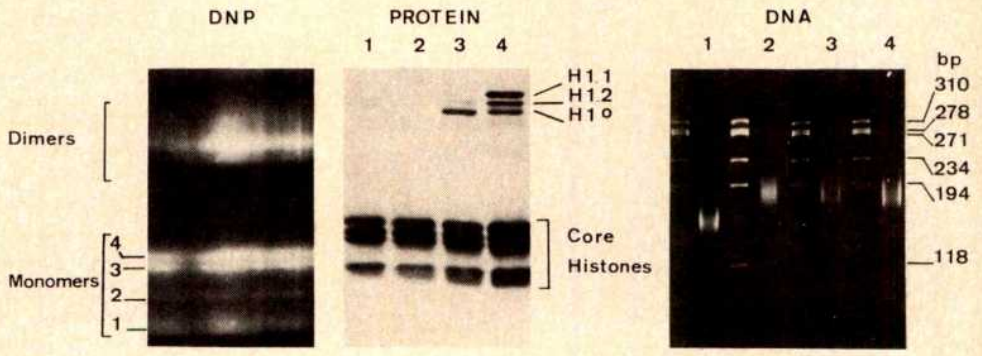

Fig. 1 DNP particle (deoxyribonucleoprotein particle) gel electrophoresis. Adult mouse liver nuclei, prepared as described elsewhere[16], were digested with micrococcal nuclease (200 U nuclease per 10^8 nuclei, 10 min at 37 °C). The digested nuclei were lysed in 0.2 mM EDTA *p*H 7, containing 1 mM phenylmethylsulphonyl fluoride. The lysate (10 A_{260} units) was fractionated by electrophoresis on a preparative 5% polyacrylamide slab gel (15×30×0.3 cm) as described by Varshavsky *et al.*[12]. Electrophoresis was performed at 200 V for 16 h at 4 °C with a continuous circulation of the buffer between the two reservoirs. The bands were visualized after ethidium bromide staining (see text for the description of the bands). Protein content of the various nucleosomes: The protein content of the DNP gel slice was obtained after electroelution in 0.025 M Tris, 0.192 M glycine, 0.1% SDS *p*H 8.3 followed by dialysis against water and lyophilization. They were then analysed on an SDS–15% polyacrylamide gel[17] and stained with Coomassie blue. DNA length of the various nucleosomes: The gel slices from the DNP gel were cut into fine particles and incubated overnight at 20 °C in 5 vol. 0.5% SDS, 3 mM EDTA *p*H 7.6 (ref. 12). Pieces of the gel were then removed by centrifugation at 10,000*g* for 10 min followed by filtration on glass wool. The supernatant was treated first with 50 g ml^{-1} RNase T1, 1 h at 37 °C, then with 100 g ml^{-1} proteinase K, 48 h at 37 °C. The extract was made 1.5 M in NaCl, cooled to 4 °C and SDS was removed by centrifugation at 10,000*g* for 10 min. The supernatant was extracted with phenol, then with chloroform[18]. Chloroform was removed by ether extraction. The DNA was precipitated with 2 vol. ethanol for 24 h at −20 °C in the presence of 10 mM $MgCl_2$ and recovered after centrifugation at 110,000*g* for 3 h in a SW 28 rotor. The pellet was then washed with 95% ethanol and DNA reprecipitated as above. Analysis of the DNA length was performed by electrophoresis on a 6% polyacrylamide gel[19]. A *Hae*III digest of RFΦX174 was used as size marker. DNA lengths are expressed in base pairs (bp).

Table 1 H1 content and DNA length of the various monomers

Class of monomers	% Monomer (relative proportion)	H1 content	% $H1^0$/total H1	DNA length in base pairs at Mean	Halfwidth
1	35	No	—	148 ± 3	140–166
2	10	No	—	183 ± 3	169–202
3	15	$H1^0$	99	177 ± 3	166–200
4	40	H1-1, H1-2, $H1^0$	20	180 ± 3	167–204
Native chromatin		H1-1, H1-2, $H1^0$	35	—	—

$H1^0$/total H1 was determined by densitometry after scanning the protein electrophoresis gel (Fig. 1). DNA length, obtained by densitometry scanning of the DNA electrophoresis gel (Fig. 1), is expressed in base pairs at the maximum absorbance and at the halfwidth of the peak.

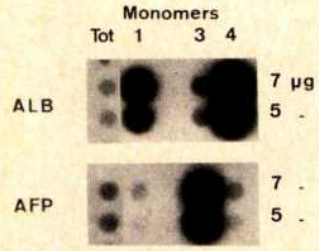

Fig. 2 Albumin and α-fetoprotein sequences among the various monomers. Purified DNAs isolated from the different monomers were hybridized to AFP1 and pmalb2 probes.

Methods. Plasmids were amplified in *Escherichia coli* (HB101) in rich medium containing 25 g ml^{-1} ampicillin and recovered by lysis of the cells with alkali[18]. They were purified by centrifugation to equilibrium in a caesium chloride/ethidium bromide density gradient and purified as described elsewhere[18]. The probes were excised by *Hin*dIII digestion[18]. They were further purified by electroelution in water after electrophoresis in 1% agarose gel in 89 mM Tris buffer *p*H 8.0, 89 mM boric acid, 2 mM EDTA and 0.025 g ml^{-1} ethidium bromide. They were then purified by chromatography on ELUTIP (Cera Labo) and precipitated with 2 vol. ethanol. The purity and the amount of DNA were estimated from the ultraviolet absorption spectra. Probes were labelled by nick-translation[18] with ^{32}P-dCTP and ^{32}P-dTTP to a specific activity of $2.2–2.5 \times 10^8$ c.p.m. per g DNA. The DNA from the various monomer fractions was dissolved in 10 mM Tris-HCl *p*H 8.0, 1 mM EDTA and denatured by heating to 100°C for 10 min. After chilling the samples on ice, an equal volume of 1 M NaOH was added and the solution was incubated at room temperature for 20 min. The DNA samples were then neutralized by adding 0.5 vol. of a solution of 1 M NaCl, 0.3 M sodium citrate, 0.5 M Tris-HCl *p*H 8.0 and 1 M HCl[18]. They were spotted directly onto nitrocellulose paper (BA 83, 0.25 µm, Schleicher & Schuell) which had been treated previously with H_2O and equilibrated with 20× SSC buffer (1×SSC buffer is 0.15 M NaCl, 0.015 M trisodium citrate) using a vacuum minifold apparatus (Schleicher & Schuell). The nitrocellulose filters were dried under a lamp and baked for 2 h at 80 °C. They were then prehybridized for 24 h at 42 °C and hybridized for 65 h at 42 °C using the technique described by Thomas[20]. The blots were exposed to X-ray film for 3 days at −70 °C using a Kodak intensifying screen. Total monomers (Tot) were prepared by two successive centrifugations on a 5–30% sucrose gradient for 21 h at 110,000*g* followed by treatment with RNase and proteinase K and purification by phenol and chloroform[18]. Equal amounts of the different DNA samples on the filters were spotted (5 and 7 µg).

other fractions tested (class 1 and 4 monomers). During maturation, the repression of the AFP gene[8,9] occurs concomitantly with the increase in $H1^0$ content[3,4]. We show here that coding sequences for the AFP gene are preferentially associated with nucleosomes bearing $H1^0$. This result reinforces the hypothesis that $H1^0$ may be involved at the level of gene expression during development.

We thank H. B. Osborne for critical reading of the manuscript and S. Tilghman for cloned DNA fragments. This work was supported in part by grants from CNRS (ATP: Développement and ATP: Organisation et expression du génome dans les Cellules Eucaryotes). Cl.G. and J.J.L. are members of INSERM.

Corrigendum

A bacterial repressor protein or a yeast transcriptional terminator can block upstream activation of a yeast gene

R. Brent & M. Ptashne

Nature **312**, 612–615 (1984)

THE fourth paragraph in the Discussion section of this article (p. 615) contained several inaccuracies resulting from the use of upper-case Greek alpha, which looks the same as the upper-case letter *A*. The paragraph should read:

There is evidence that other yeast genes can be repressed by negative regulatory factors bound between the upstream activator sequence and the TATA region. For example, it is likely that *MATα1* transcription is repressed in diploid yeast by binding of a negative regulatory factor (which is dependent on the expression of *MATA1* and *MATα2*) to a site between the *MATα1* upstream activator sequence and its TATA region[16]. *STE6* transcription is repressed by the *MATα2* product, which binds to a specific site in the *STE6* promoter, probably located between the upstream activator sequence and the TATA region (A. Johnson, K. Wilson and I. Herskowitz, personal communication). The repression of *MATα1* and *STE6* is at least 50 times greater than the 10-fold repression we observe for *lexA* operator-containing derivatives of the *GAL1* promoter. We do not understand why these yeast promoters are repressed so efficiently relative to the *lexA* operator-containing *GAL1* promoter.

Sequence similarity between EGF receptor and α_1-acid glycoprotein

THE human epidermal growth factor (EGF) receptor precursor consists of three domains, an extracellular EGF binding domain, a single transmembrane domain and a cytoplasmic domain. Ullrich *et al.*[1] recently determined the complete amino acid sequence of the molecule and showed that the latter two domains exhibit close similarity in sequence to the entire v-*erb-B* oncogene product, a member of the *src* family. By aligning cysteine residues, they also found repeated structures of ~170 residues within the extracellular domain[1]. A similarity matrix comparison[2], however, revealed the presence of further extensive homology between regions of ~300 residues located at positions 1-274 and 294-615, which cover almost the entire extracellular domain (Fig. 1). Of all the positions compared in the aligned sequences, 28% are occupied by identical residues (gaps were considered as substitutions between different amino acids regardless of their length). Furthermore, a statistical test[2] showed that the similarity between the aligned sequences is highly significant, with a probability of occurrence by chance of $<10^{-9}$. Thus, the extracellular EGF binding domain consists of tandemly repeated domains which may have evolved by internal duplication. Alignment of their sequences also revealed that each repeat is composed of an N-terminal conserved region and a C-terminal cysteine-rich region.

We subjected the amino acid sequence of the EGF receptor to a computer-assisted search for homology with ~2,500 known sequences compiled in our database and found apparent sequence similarity between the C-terminal half of the EGF binding domain and α_1-acid glycoprotein (α_1-AGP), known to be an acute-phase protein[3] (Fig. 1). A statistical test shows the similarity to be highly significant, with $P = 3 \times 10^{-7}$.

Interestingly, the α_1-AGP molecule has been shown to exhibit weak sequence homology to immunoglobulin[3] as well as to part of the variable domain of the mouse T-cell receptor ($P < 3 \times 10^{-4}$). Thus, it seems likely that the EGF binding domain is indirectly related to the immunoglobulin superfamily. Lack of significant similarity between the N-terminal half of the EGF binding domain and α_1-AGP may be a result of rapid divergence in the N-terminal half, relative to the C-terminal half, presumably during the earlier evolutionary stage after the separation of the two domains by internal duplication. In addition, the transmembrane segment of this receptor bears a close resemblance to that of the HLA class II β-chain ($P < 5 \times 10^{-4}$).

These results, together with evidence that the cytoplasmic domain contains an *src*-related sequence[1], suggest that the extracellular and cytoplasmic domains may have been derived from evolutionarily independent origins and thus that this large receptor gene may have evolved by gene shuffling and partial duplication. We cannot exclude the possibility, however, that an ancestral α_1-AGP gene was derived from a part of the EGF binding domain.

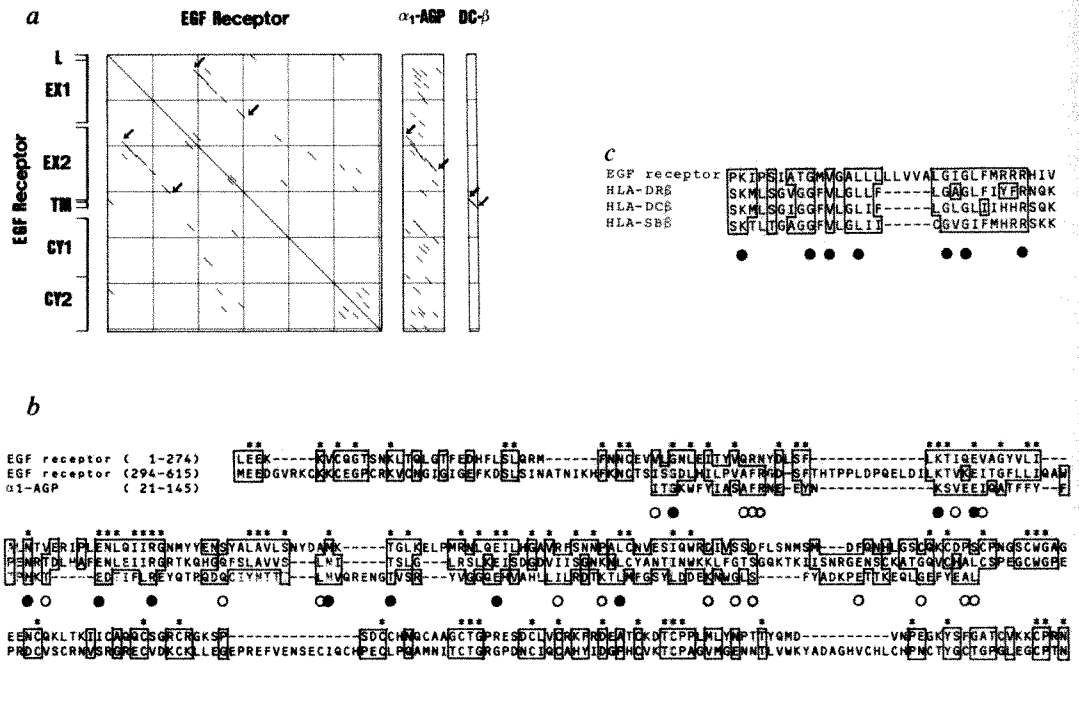

Fig. 1 *a*, Similarity matrix comparisons of amino acid sequence of EGF receptor (ordinate) with the sequences of itself, α_1-AGP and the transmembrane segment of HLA-DC β-chain (abscissa). A computer program was used to generate diagonal lines indicating segments of 25 residues which show sequence similarity (see ref. 2). L, signal peptide (positions −24 to −1); EX1, EX2, duplicated regions (1-274 and 294-615) of the extracellular EGF binding domain, respectively; TM, the transmembrane segment (622-644); CY1, CY2, *src*-homologous and -non-homologous regions (690-936 and 967-1,186) of the cytoplasmic domain, respectively. Arrows indicate regions where extensive similarities were detected. *b*, Alignment of amino-acid sequences of N-terminal (EX1) and C-terminal (EX2) halves of the EGF binding domain and α_1-AGP. Boxed residues indicate identities or favoured amino-acid substitutions (see ref. 2). Positions where residues are identical between EX1 and EX2 and between EX2 and α_1-AGP are marked by * and ○, respectively. Invariant residues among the three are indicated by ●. Gaps (—) were introduced to maximize similarity. *c*, Alignment of transmembrane segments of EGF receptor and HLA class II β-chains. Regions where sequences were aligned correspond to positions 617-650 and 197-225 of the EGF receptor and HLA-DCβ, respectively. Boxed residues indicate identities (●) or favoured amino-acid substitutions between EGF receptor and HLA chains.

Stomatal mechanism as the basis of evolution of crassulacean acid metabolism

KEELEY *et al.*[1] have demonstrated clearly that the rare pteridophyte, *Stylites andicola* (Isoetaceae), exhibits a variant of photosynthetic carbon metabolism which has obvious affinities with crassulacean acid metabolism (CAM). They also drew attention to the absence of stomata in *Stylites* and concluded that these findings taken together indicate that this unusual organism does not conform to the hypothesis that CAM may have evolved from stomatal guard cell metabolism[2].

However, as other members of the Isoetaceae possess stomata, it may be that *Stylites* evolved from ancestors that did possess stomata and although it does not itself possess these structures, it may nevertheless use pathways derived from guard cell metabolism.

Thus the discovery of a CAM-like photosynthetic mechanism in *S. andicola* is not necessarily inconsistent with the evolution of CAM and associated pathways from stomatal guard cell metabolism.

W. COCKBURN
Department of Botany,
University of Leicester,
Leicester LE1 7RH, UK

1. Keeley, J. E., Osmond, C. B. & Raven, J. A. *Nature* **310**, 694-695 (1984).
2. Cockburn, W. *Pl. Cell Envir.* **4**, 417-418 (1981).

THE suggestion by Keeley *et al.*[1], supported by Moore[2], that *Stylites* may represent an important link between aquatic plants and primitive land plants has little foundation in fact. To go further and propose that these plants could be relics of a marginally successful compromise from which present-day terrestrial photosynthetic systems were selected runs contrary to our views on plant evolution. *Stylites*, whose separation from *Isoetes* is questionable, is regarded generally as a descendant of a long line of lycophytes and should not be thought of as primitive plants. Specifically, they most probably evolved from woody-stemmed plants with cormose bases, such as the Carboniferous swamp plant *Chaloneria*. These early lycophytes certainly possessed stomata[3]. *Isoetes*-like plants existed in the Triassic and probably spread along the coastal plains before moving inland. These are terrestrial species of *Isoetes*, shallow-water-living species (of which some have emergent sporophylls and others are totally submerged) and species living on the bottom of deep-water lakes. This migration into water resulted in the loss of stomatal function in shallow-water-living species (for example, *Isoetes malinverneana*) and the total loss of stomata in the deeper living species (for example, *Isoetes lacustris*)[4]. The most plausible argument for *Stylites* not possessing stomata is that it lost them through submergence, not that its ancestors never possessed them.

It is true that in its type locality, *Stylites* grows above the water level, but plants have been found repeatedly that grow submerged. The lack of an efficient method of dispersal suggests that the plants have been growing in the same area for a very long time. The substantial elevation of the high Andes in relatively recent geological times could explain both their geographical isolation and the loss of their aquatic habitats.

The fact that both *Stylites* undergo CAM similar to the aquatic species of *Isoetes* is therefore not necessarily surprising. *Stylites* should not be thought of as evidence that CAM did not evolve from stomatal guard cell metabolism. It is more probable that its ability to convert to CAM as it invaded an aquatic environment saved it from extinction.

B. A. THOMAS
Department of Life Sciences,
Goldsmiths' College,
University of London,
London SE14 6NW, UK

2. Moore, P. D. *Nature* **310**, 633 (1984).
3. Pigg, K. B. & Rothwell, G. W. *Bot. Gaz.* **144**, 132-142 (1983).
4. Masarati, D. L. & Thomas, B. A. *Phyta*, 155-162 (1982).

KEELEY *ET AL.* REPLY—We agree with Cockburn that, although the presence of CAM in astomatous *Stylites* does not support his theory on the stomatal origin of CAM, it does not necessarily falsify the theory either.

We also agree with Thomas that *Stylites* most reasonably should be included with *Isoetes*, a taxon dating back only to the Triassic. Lycophytes, however, extend back to the Devonian. Although it has been proposed that *Isoetes* represents a reduction from a tree-like lycopod, it is clear that herbaceous lycophytes have been present since the Carboniferous and form the longest unbroken time record of any group of vascular plants[1]. We do not believe that *Stylites* (*Isocetes*) *andicola* was the first vascular land plant, but it may represent a model system for how vascular plants invaded seasonally dry terrestrial environments.

The view of the morphological evolution of *Stylites* which Thomas presents agrees with the known fossil record of the Isoetales (see Thomas and Brack-Hanes[2]). It is also consistent with two arguments proposed by Raven[3] as to the physiological significance of morphological attributes in vascular plants, the first of which relates to the presence of xylem tissue in *Stylites*. The probable earliest function for xylem was that of water conduction rather than mechanical support. Transpiration does not necessarily imply the presence of stomata (compare with the extant *Polytrichum* and the Siluro-Devonian *Cooksonia*), but it does indicate that a phototroph obtains CO_2 from the air rather than the sediment. The second argument relates to the presence of intercellular air spaces which seem to be correlated with the presence, or occurrence at some stage in the plant's evolutionary history, of epidermal pores (Marchantiales) or stomata (sporophytes of vascular plants). These arguments suggest that *Stylites* was derived from transpiring ancestors that possessed stomata and derived CO_2 from the atmosphere rather than the sediment. However, Raven[3] noted that "the sequence of acquisition of H_2O-conducting and gas-exchange/regulation mechanisms revealed by the fossil record is generally in accord with teleological expectation, in that the H_2O-conducting system in the absence of the gas-exchange/regulation mechanism would be of more selective advantage than the reverse state of affairs". *Stylites* may represent such a survivor.

Thomas' conjecture about the evolution of *Stylites* is not consistent with our observations. Although it is possible that *Stylites* 'lost' stomata, the argument proposed by Thomas is not plausible; he points out that deep-water *Isoetes* (for example, *I. lacustris*) have totally lost stomata and that the lack of stomata in *Stylites* may derive from a previous aquatic ancestry. Although aquatic *Isoetes* species from deep water are astomatous, all such species so far tested (including *I. macrospora*, considered to be conspecific with *I. lacustris*[4]) will produce stomata on leaves initiated under 'artificial' aerial conditions (J.E.K., unpublished data).

The important feature of the astomatous habit of *Stylites* is the reliance on sediment carbon. Data on *I. triquetra* from the high-altitude paramo of the northern Andes (J.E.K., unpublished) and descriptions of the recently discovered *I. hopei* Croft from the topical alpine of New Guinea suggest that this syndrome, although rare, may be widespread globally in the Isoetaceae.

NEW updated and expanded edition of...

Stockton Press Paperback 464pp 297 x 210mm
ISBN 0-943818-03-6 **November 1984 $130.00**

The most comprehensive single source of up-to-date authoritative information on today's biotechnology world.

Now *The Biotechnology Directory* gives you even more data to help you keep right up to date with important developments in this fast moving industry.

- ★ Over 1200 NEW entries
- ★ **NEW full entries** for Australasia and Brazil, plus more information on UK, USA, European countries and Japan.
- ★ Over 950 products and services in Buyers' Guide.
- ★ **NEW journals** More than 100 updates, including changes of prices and addresses, as well as details of new journals and newsletters.
- ★ Over 4000 entries for commercial and non-commercial organizations.
- ★ **NEW** comprehensive alphabetical index to directory's unique Buyers' Guide to products, research and services, fully cross referenced to speed access to data.

Moreover, the directory covers both the old established biotechnologies — brewing, food processing, pharmaceuticals and waste treatment — and the new advancing genetic engineering technologies.

Worldwide coverage

The directory covers **all** the countries where the biotechnology industry is most active today: Australia, Austria, Belgium, Brazil, Canada, Denmark, Finland, France, Germany, Greece, Ireland, Israel, Italy, Japan, Netherlands, New Zealand, Norway, Portugal, Spain, Sweden, Switzerland, United Kingdom and the United States.

AVAILABLE ON 10 DAYS FREE APPROVAL SEND NO MONEY NOW

Comprehensive range of hard information allows you to identify and compare accurately:

- International organizations
- Government agencies and programmes
- Information sources
- Societies and associations
- Non-commercial organizations
- Commercial companies active in biotechnology

Authoritative author

Dr. Jim Coombs is a consultant for the EEC on the Biomass for Energy Programme, and the EEC's Forecasting and Assessment in Science and Technology (FAST) Programme for Biotechnology. He is editor of *Biomass* and Secretary of BABA.

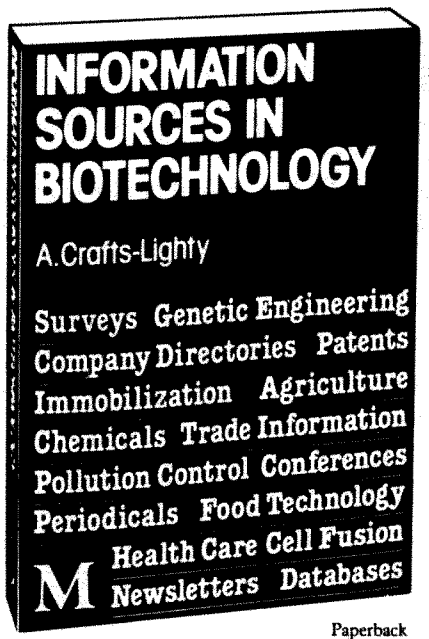
Without the directory you will not be completely up-to-date and not entirely competitive. Take a copy on FREE APPROVAL and judge for yourself.

Send no money now — examine on FREE APPROVAL

Take *The Biotechnology Directory 1985* on free approval for 10 days without commitment to purchase. Decide to keep the directory, then simply pay the invoice accompanying the book. If you are not convinced that it is a sound investment at $130.00, just return the book in good condition within 10 days with the invoice. Complete the order form below **now** to ensure prompt delivery.

Your guide to the selection of cost-effective biotechnology information sources

Evaluates and assesses the whole range of information sources available.



- covers databases and directories
- covers technical and commercial literature.
- covers difficult and hard to trace sources.
- includes over 20 at-a-glance evaluation tables.
- provides an Index of publishers and their addresses.

Dr. Crafts-Lighty, Information Manager for Celltech Ltd., systematically and critically reviews

★ books ★ conferences ★ trade periodicals ★ research periodicals ★ computer databases ★ patents ★ market surveys ★ directories ★ organisations ★ secondary sources.

With her specialist guidance you can save time and money by selecting the really cost-effective sources of information.

Order your copy **NOW.**

Chemotherapeutic Strategy

Edited by
Dr.D.I. Edwards
Reader in Microbiology
Head of the Chemotherapy Research Unit,
North East London Polytechnic
D.R. Hiscock
Senior Lecturer in Pharmacology, North East London Polytechnic
£25.00; 232pp; ISBN 0 333 34318 2

The development of new drugs all too often involves the random screening of potential new compounds — a time-consuming and costly process. This book reviews how a more rational strategy to new drug formulation can be developed through the adoption of a multidisciplinary approach. Based on a symposium held in June 1982, three major aspects are discussed: the targets within the susceptible cell (including resistance); problems of the chemotherapy of infection (including cancer); and new approaches to chemotherapeutic strategy, which are of current interest and which may have value in the future.

Contents

Contributors; Preface; Antibiotics affecting DNA function — *S. Neidle*; Antimicrobial agents affecting membrane function — *S. Hammond*; Antibiotics affecting microbial cell walls — progress after 112 years — *S. Selwyn*; Antibiotics as probes of ribosomal structure and function — *E. Cundliffe*; Mechanisms of drug resistance — *J.T. Smith*; New strategies in the search for antiprotozoal drugs — *B.A. Newton*; Anthelmintic chemotherapy — *R.E. Howells*; Major problems in cancer chemotherapy — *K. Hellmann*; Chemotherapy of anaerobic bacteria — *A.T. Willis*; The strategy of drug development in hypoxic cell radiosensitization and chemosensitization — *I. Stratford*; Quantitative structure-activity relationships (QSARs) — principles and practice — *P. Wardman*; Three-dimensional aspects of molecules in drug design — *J. Tollenaere*; Targeting of drugs with liposomes — *G. Gregoriadis*; Index.

Asdic to sonar

R.V. Jones

Seek and Strike: Sonar, Anti-Submarine Warfare and the Royal Navy 1914–54.
By Willem Hackmann.
Her Majesty's Stationery Office: 1984. Pp.487. £15.95.

THE detection and location of submarines in the sea has one factor in common with the analogous processes associated with finding aircraft in the air — the transmission of wave-borne energy. But while the air is a nearly uniform and transparent medium to electromagnetic radiation, and while an aircraft is a palpable discontinuity in that medium, the sea is effectively opaque over almost the entire range of the radio spectrum. It was therefore quickly realized that the detection of submarines would have to depend on acoustic waves — mechanical waves which need transducers for their generation and reception, a further contrast with radar, where radio waves are launched from and received by antennae which are simple extensions of electronic circuitry. As a result, once the problem of aircraft detection was formulated, the radar solution was brilliantly found and exploited to such an extent that in the decade 1935–1945 almost all the essential techniques had been developed.

No such exhilarating story can be told of submarine detection. Instead, it has provided one of the greatest challenges to the application of physics, where ground has been won only by prolonged effort. *Seek and Strike* records what was done in Britain between 1914, when the impact of the U-Boats was first felt, and 1954, when submarine warfare entered a new phase with the launching of the first nuclear submarine — the *USS Nautilus*.

The author, Willem Hackmann, is Assistant Curator of the Museum of the History of Science at Oxford, and he appropriately starts his account with the speculations of Aristotle and Pliny the Younger on the detection of underwater sound by fish. This has its analogy in the use of hydrophones to detect submarines by sound generated by their engines or hydrodynamically by their passage through water; this technique has been developed to detect submarines at ranges of hundreds of miles, but it is limited operationally both by the vagaries of transmission in a medium whose refractive index varies with salinity and temperature, and by a background of other noises generated not only by surface waves and ships, but also by such modest creatures as snapper shrimps.

While hydrophones can give general, and indeed impressive, warnings, ultrasonic echo detection — which gives range as well as bearing — is necessary to locate a submarine precisely enough for it to be attacked. Hackmann gives the credit for the original development of the method to Paul Langevin, but it may be worth mentioning that James Wilson in his recent biography suggests that some of it should also go to Rutherford.

The author has clearly done a great deal of painstaking work in pursuing the many aspects of a long and involved story, and in refining them into a readable and admirably documented account. Several points emerge from it. First, despite the fact that the Royal Navy appreciated as long ago as 1873 the importance of science when it founded the Royal Naval College at Greenwich to ensure that naval officers would study both science and mathematics, and despite the enthusiasm for science and engineering shown by Admiral John Fisher, few naval officers were prepared to take scientists fully into their confidence, even when faced with the U-Boat threat. Instead of letting scientists such as Rutherford experience the conditions of hunting U-Boats at sea for themselves, the chief naval liaison officer demurred, saying that all that the scientists need be told "was that the enemy submarines were in the sea and that means were required to detect their presence". Only after the advantages of close cooperation between scientists and serving officers had been demonstrated in air defence in the Second World War were the Services completely won over.

Another feature of the development of Asdic (or Sonar) was the continuous battle between long and short term interests: should greater priority be given to the development of a weapon for tomorrow or to research that might provide a much better weapon the day after tomorrow? The right answer depends on circumstances; but in naval weapons, such as Asdic or signalling, the answer was more often than not determined in favour of the short term, because appointments in the Navy have characteristically a two-year duration, and so captains of establishments such as The Signals School tended to favour programmes from which they might expect some concrete result within their term of office.

A further message is the danger of "overselling" a weapon, causing first an unjustified reliance on its performance in operations, and then a loss of confidence when its shortcomings become clear, as exemplified by Churchill's complaint to the First Sea Lord in 1941 about Asdic — ". . . the failure of our methods, about which so much was proclaimed by the Admiralty before the war". And yet another is the merit of trying a technique or system "the other way round", in this case the firing of the depth charges ahead over the bow of the hunting ship instead of dropping them over the stern, which led to an increase in success rate from about 7% to about 30% as a proportion of kills to attacks.

All these lessons, which have relevance far beyond submarine warfare alone, are to be found in the book. Alongside them are such morsels as the attempts of 1915 to train seagulls to hunt for U-Boat periscopes; the renaming of the quartz crystals required for piezoelectric transducers as "asdevite" to avoid disclosing their composition, and the recruitment of a firm of tombstone-makers to cut the crystals; and the fact that even a noisy submarine radiates no more energy than would light a 3-volt torch bulb.

Seek and Strike tells a story of successes tempered with failures in the sustained application of physics to one of the most crucial problems of warfare this century. It was well worth writing — and is well worth reading — both for its significance as history and for the lessons it exemplifies.

R.V. Jones is Emeritus Professor of Natural Philosophy at the University of Aberdeen and Chairman of the Defence Committee of the Centre for Policy Studies, London.

Pioneers of ultrasonic echo ranging; Paul Langevin is fourth from the left, wearing the bowler hat. The photograph was probably taken at Toulon in May 1918.

Breeding discontent

David Pearce

The Plutonium Business and the Spread of the Bomb.
By Walter C. Patterson.
Paladin: 1984. Pp.272. Pbk £2.95.

THERE are, says Walter Patterson, "nuclear people", "plutonium people" and "fast breeder people". Nuclear people believe in the civilian use of nuclear power for electricity. Plutonium people and fast breeder people believe in the original nuclear dream: the widespread use of plutonium — a by-product of burning uranium fuel — as a fuel for fast reactors which can breed more plutonium. Nuclear people need not be plutonium people but they share the same vision, that of a resource with enormous potential. If the resource is there they cannot understand why it should not be used. Yet resource use has costs as well as benefits; nothing comes free.

Patterson sets out to chart one of the costs of plutonium. The civilian nuclear power dream cannot be distinguished from plutonium as a weapons material, despite all the protestations by plutonium people to the contrary. This he does most successfully in an historical overview from Seaborg's identification of plutonium, through the Manhattan Project, to today's aggressive fast breeder programme in France and the limited triumphs and many failures elsewhere. The Super-Phénix is nearing completion in France at a cost of some $10,000 million. It is jointly owned by France, Italy, Germany, Britain, the Netherlands and Belgium. Patterson is quite clear how such a staggering cost is justified by advocates of the programme — it will provide military plutonium when other supplies have gone. We are all, it seems, helping to finance French nuclear weapons.

Patterson sees no hope in existing safeguards against the spread of military plutonium from civilian sources, whether in the International Atomic Energy Authority or the Non-Proliferation Treaty, the subject of so many ambiguous and confusing interpretations. For the truth is that no one knows collectively how much plutonium exists. One "best guess" for 1982 suggests some 175 tonnes of plutonium "in stock" in *civilian* sources in the non-communist world (though this appears not to account for high-purity plutonium from Magnox reactors which, if evidence to the Sizewell Inquiry is correct, actually has been diverted to US nuclear weapons). The annual production rate of plutonium is about 40 tonnes. The prospect of control thus seems remote.

In the same light it is easy to see why plutonium people are not concerned about the niceties of nuclear power economics. Any breeder reactor should be credited with the "value" of the plutonium it produces. By the same token, in the absence of a large breeder programme, all *conventional* nuclear power stations should be credited with the value of the plutonium in their spent fuel. That value lies in the benefit to world security from having nuclear weapons, a value many will find difficult to believe is less than a very large minus number indeed. But if this is the "real" economics of nuclear power why don't plutonium people admit it? The majority may not dispute the positive value of nuclear weapons. The answer may be that most plutonium people, just like most people, do not know the connection between civilian and military plutonium.

The alternative is that they *do* know the link but cannot see how stopping the civilian programme would help. After all, the weapons programme began with reactors dedicated to military plutonium. Electricity was incidental. Patterson offers no guidance on this point. For him it is enough that plutonium production is already out of control. With only a short time to go to the fortieth anniversary of Nagasaki we can only contemplate whether the lapse of time is the truest testament to man's ability to control his fearsome drive to self-destruction, or just an interlude between appalling but vastly different events. □

David Pearce is Professor of Economics at University College London.

Talk of Kyoto

F.S. Rosen.

Progress in Immunology V.
Edited by Y. Yamamura and T. Tada.
Academic: 1984. Pp.1,640. $110, £85.

IN August, Kyoto is inhospitably hot. Certainly Baedeker, if he ever had reached there, would have found it situated in an unhealthy valley, nonetheless worthy of being reached in slow stages from Edo by the great Tokaido so beautifully depicted in the wood-block prints of Hokusai and Hiroshige. Instead, in August 1983, some 4,000 immunologists were disgorged in haste from the bullet trains, arriving with frequent and clockwork regularity from Osaka and Tokyo, for their triennial self-congratulatory pow-wow.

Over 150 dense, compact summaries of all the symposium lectures have been published in this thick volume. It is a timely and state-of-the art overview of the whole field of immunology, in just over 1,600 pages of well-set, readable print. To read it from cover to cover is mind boggling, but certainly very informative. Summaries of the dozens of work-shops which took place during the congress are not included but that does not detract from the book; it might have resulted in overkill. Anthony Watkinson recently pointed out (*Nature* **312**, 201; 1984) that "the transformation of a transient three or four days of academic exchange into an enduring collection of reviews can be an invaluable contribution to learning". *Progress in Immunology V* measures up to just that.

On the fourth afternoon of the meeting, a spontaneously exuberant moment occurred when it became apparent that the T cell receptor had at long last been identified in Denver and Boston, in California and Texas. It was one of those rare times when an international congress is ignited by the tinder of a major discovery. Unfortunately, not all of the presentations at that session have been included. While dwelling on the omissions from this volume, it should be noted that there was almost nothing in the congress on immunodeficiency at a time when, among other things, AIDS is creating a stir and yielding information on lymphocytotropic retroviruses. There is also an omission of neuroimmunology at a time when immunology has provided interesting probes for the neurobiologist. And there is barely a nod in the direction of transplantation biology despite some good summaries of the current status of work on the major histocompatibility locus in mouse and man. Maybe all this will be fixed next time around.

Immunologists are returning to their roots with some highly productive and heuristic results. The articles by B.B. Bloom on leprosy, A. Capron on schistosomes and the Nussenzweigs on malaria are vivid demonstrations of how useful immunology can still be to its parent science. The emergence of synthetic vaccines also promises to burgeon into something usefully applicable, and current work in Israel and France on this subject is also well summarized.

The best subject coverage in the book concerns the molecular biology of the immunoglobulin and major histocompatibility genes. This field has moved very rapidly as can be gleaned from the outstanding summaries by D. Baltimore, L. Hood, T. Honjo and others. In contrast there are the still muddy fields of lymphokines, growth factor and other humors. They are desperately in need of being set right.

The high specific gravity of this tome is occasionally relieved by inspirational words, by D.W. Talmage, N.A. Mitchison and R.A. Good, that set the field in perspective. The opening reflections of B. Benacerraf epitomize the message of this meeting: "Nature rewards and yields its magic secrets to the most daringly imaginative. Hard work and dedication, while essential, are not enough". Time will tell if this challenge is to be met at the next congress in Toronto in 1986, and if that meeting too produces such a profusion of progress and excitement. □

F.S. Rosen is James L. Gamble Professor of Pediatrics at Harvard Medical School, and Head of the Immunology Division at the Children's Hospital, Boston.

An inside view

Sean C. Solomon

Planetary Interiors.
By William B. Hubbard.
Van Nostrand Reinhold: 1984. Pp.334. $42.50, £49.75.

THE United States planetary programme is midway through a five-year hiatus in major new observations from spacecraft missions, and an increasing number of American scientists are filling the gap by writing textbooks and monographs on various aspects of planetary science. Hubbard's offering treats the physics and chemistry of planetary interiors, covering all the planets (save Pluto) and most of the larger satellites viewed to date by spacecraft. The text incorporates material up to mid-1983, including results from the Voyager Saturn flyby and Pioneer Venus, but not the Soviet Venera 13-16 missions to Venus. A background in physics, chemistry, astronomy and geology at the level of a senior undergraduate or first-year graduate student is assumed.

The author has attempted a laudably comprehensive treatment of his subject. Discussion of the bulk composition and internal differentiation of each planet is cast in the framework of the composition of the Sun and the evolution of the solar nebula. Particularly thorough chapters are included on equations of state and planetary gravitational fields, both topics on which the author has made a number of original contributions. Accounts of the energy budgets of planetary interiors and the nature of planetary magnetic fields complete the foundation for the final half of the book, a thorough and quantitative inside tour through most of the principal objects of the Solar System.

Hubbard admits at the outset that "a single author has difficulty in writing a current, comprehensive book" on the planets. As if to prove the truth of this assertion, variations in the depth and evenness of coverage betray the background and research interests of the author. There is an implicit bias towards the outer planets, which first becomes apparent in the discussion on equations of state. The only silicate treated is "rock", defined as "that component of [nebular] condensate which is left after formation of an iron core". A chapter on the interior of the Earth is exposed as perfunctory with the opening apology that "this book is about the interiors of other planets"; worse, it contains misleading or incorrect statements about mantle convection, the nature of seismic discontinuities in the upper mantle and the evidence for a solid inner core.

There is a parallel bias towards an astrophysical, rather than a geological, approach to the planets. One telling statistic is that there is only a single photograph of a planetary or satellite surface (of the Discovery scarp on Mercury). The reader will find only cursory mention of cratering, volcanism, tectonics and lithospheric evolution on the solid planets and satellites. Much of the material on the terrestrial planets appears to have been taken either from the work of the author's colleagues or from a few selected review papers.

Perhaps these shortcomings are visible only from my own geocentric viewpoint. To an alien observer, the large outer planets would initially be the most interesting and an astrophysical approach to their study would be natural; indeed, our discovery and investigation of other planetary systems is, in fact, progressing in this fashion. At least from this cosmic perspective, *Planetary Interiors* is the most current and complete treatise available. □

Ode to diversity

Lindon J. Eaves

In Praise of Difference: Genetics and Human Affairs.
By Albert Jacquard.
Columbia University Press: 1984. Pp.187. $20.

"THE essential nature of the Darwinian revolution was. . . the replacement of a metaphysical view of variation among organisms by a materialistic view". Thus Richard Lewontin (*The Genetic Basis of Evolutionary Change*, 1974, p.4) described the impact of biology on our understanding of life: an impact which has only been magnified by the ability, recently acquired, to extract and hold in our hand the molecular basis of life.

Against this background of the "scientific challenge" to traditional ideas, our acceptance of reproductive technology has already led to a radical adjustment in the norms of society with regard to the control of fertilization and the outcome of pregnancy. How far should we go down this road? In his preface Professor Jacquard writes:

> Human endeavor, based on a growing knowledge of both the inanimate and the living world, has become increasingly effective. Why not use this new power to achieve the most tempting objective of all: the improvement of the human species itself?

Popular ignorance of the main scientific ideas and facts involved is the first barrier to democratic decision-making, so Professor Jacquard begins by outlining the elementary reproductive and evolutionary processes as simply as possible and later discusses some of the mechanisms which can lead to the high level of polymorphism not predicted from classical theory in population genetics. His treatment of these issues is simple and lucid and will be readily comprehensible to the general reader. Having outlined the basic biological issues, Professor Jacquard focuses on subtleties which are sometimes ignored by advocates of a genetic basis to social policy and he tries to give a more balanced view of debatable ideas which are sometimes treated as "facts" in the popular mind. Among the problems he addresses are the "dysgenic" effects of medicine which, he argues, would take place extremely slowly even if they were not offset by such factors as genotype - environment interaction. His statement about consanguinity warrants some qualification. When writing of the origin of rules prohibiting consanguinity, he says (p.50), "the ill effects of consanguinity . . . are much too slight to be observed empirically". It must be presumed that he is thinking about cousin marriage, since the effects of closer consanguinity on mental retardation, for example, are well documented.

The book points, indirectly, to the separation of population genetics from quantitative genetics which has characterized much of the development of both disciplines. Professor Jacquard's strength is in population genetics. When he turns to quantitative genetics and psychometrics he does not do justice to the best of either subject. For example, he invests great effort in criticizing an additive model for individual differences without asking why such a model often fits the data remarkably well. And he criticizes the concept of general intelligence without addressing the more interesting question of why multiple abilities are correlated.

Bertrand Russell observed that moral considerations could only appear when the truth is known and should not be used to decide what the truth is. There are few moral propositions in the book from which the sensitive reader is likely to dissent. Man's unalienable right to "life, liberty and the pursuit of happiness" is maintained, whether it be given by God, history or DNA. In spite of the growth of knowledge, we do not have all the facts to manipulate the future of the species in the broadest sense. Is this so bad? Professor Jacquard suggests that it is not. The title of his book reflects his belief, expressed in the final chapter, that human diversity, guaranteed by the mechanisms of inheritance and natural selection, is a treasure which should not be sacrificed before any idol of "progress" or "uniformity". This principle extends as much to the fruits of man's intellect as it does to the species itself. The dissemination of scientific ideas, and their open discussion divorced from political influences, is the best insurance that science will remain a guardian of freedom rather than a slave to totalitarianism. □

Practice of science

Russell Moseley

Philosophy and Sociology of Science: An Introduction.
By Stewart Richards.
Basil Blackwell/Schocken Books: 1984. Pp.210. Hbk £17.50, $20; pbk £5.95.
An Introduction to Science Studies: The Philosophical and Social Aspects of Science and Technology.
By John Ziman.
Cambridge University Press: 1984. Pp.203. £12.95, $22.95.
The Experience of Science: An Interdisciplinary Approach.
By Martin Goldstein and Inge Goldstein.
Plenum: 1984. Pp.400. $22.50, £21.38.

THE more dogmatic features of an undergraduate education in science (almost as bad as orthodox theology according to Thomas Kuhn) are well known and are enshrined each year in thousands of examination questions which require candidates to demonstrate their competence in solving puzzles within well-established frameworks. Those examining conventions which today we take for granted have not always been so closely observed. Cambridge science students in the 1850s were invited to consider whether there was "a shadow of proof from the ethnographical and physical history of man that any one of his oldest varieties was derived from a quadruminous progenitor" and were urged to state their own opinions "without hesitation" should they differ from those of the examiner. But by and large undergraduate science students have not been encouraged to question either the status of the knowledge acquired in their apprenticeship or, indeed, the nature of the scientific enterprise more generally. Not surprisingly then, studies which seek to encourage such questioning have met with a mixed reception.

Visitors to the cave paintings of Lascaux in France, shortly after the cave's rediscovery in 1940. The picture is reproduced from the new paperback edition of The Creative Explosion, *by John Pfeiffer, published by Cornell University Press. For review see* Nature **302**, *764 (1983).*

To reduce the possibility of outright rejection it becomes necessary to establish the legitimacy of "science studies" and to convince students of the need to view them as an integral part of a scientific training rather than something which derives from a nineteenth-century belief in the virtues of a liberal education. In this respect students are more likely to take notice if these matters are addressed by *bona fide* scientists, and all three of the books reviewed here share this advantage. Credibility in students' eyes may be further enhanced by claims for the utility of science studies, and each book contains a justification for such teaching over and above "metascience" (as Ziman calls it) for its own sake. Thus Richards begins with a recollection of the value to his later career of an undergraduate course in the history and philosophy of science, while Ziman sees "a possible guide to action in scientific research, in industrial management, in political administration, and in public affairs". Once credibility has been established a major problem remaining for the would-be teacher of science studies is the choice of material — there is no agreed core curriculum here but a spectrum extending from the philosophy of science to the economics of technological innovation. This is a difficulty which confronts any author writing a book on science studies, and the problem of providing material and a structure which will be sufficiently flexible to find use in a broad range of courses has no easy solution. Since all three books make claims to be suitable undergraduate texts, their success in this respect deserves careful consideration.

An additional obstacle to be overcome stems from the constantly growing specialist literature generated by those historians, philosophers, sociologists, economists and political scientists who contribute to the science studies area. Both Richards and Ziman are acutely aware of this — their titles make it clear that we are dealing with "an introduction" — and both authors offer their work as a guide to an interpretation of the wider literature and as a means of presenting themes which they identify as being of particular importance. For a reviewer this poses a problem. To engage in a discussion of the authors' interpretation of debates in the philosophy of science, the sociology of science, science policy and so on, would be an undertaking which would result in another (introductory) text. Instead it seems preferable to focus on the appropriateness of the particular guided tours we are being offered in the light of their stated purpose.

The routes taken by both Ziman and Richards are, at first glance, very similar, starting with a broad look at selected features of the philosophy of science, moving on to the sociology of science and science policy, bringing us finally to more general cultural matters. Both tours finish rather abruptly, with neither guide attempting any recapitulation of those features which were of special interest — presumably they are taken to be self-evident if the tourist has been paying attention. Despite the apparent similarities there are some significant differences. On the whole the Ziman route is the more stimulating, revealing some unexpected views, striking out on paths only recently discovered and generally traversing the terrain at a faster pace. The Richards party will certainly get their money's worth, but will miss some of the newer landmarks, will avoid some of the higher slopes, and generally travel more sedately.

Ziman is noticeably the stronger in his discussions of recent work in the sociology of science and is more successful in linking his themes throughout the book. Richards more clearly divides his work into "Methods and Philosophies of Science" and "Interactions of Science and Society". The least satisfactory part of both books is that dealing with the organization of research and development and technological innovation — at this point the tourist may find his or her attention wandering (to be fair, neither author sets out to treat the broad area of science, technology and society comprehensively, but questions concerning the economics of research and development and technical change are a part of science studies, and one for which students often show considerable interest). Similarly, the history of science is allowed little more than a token appearance. Students using either of these books will need to be reminded that the Ziman and Richards routes are not the only ways of seeing the landscape and that others have been mapped out.

The Goldsteins offer an alternative approach, and the intended use of their book as an interdisciplinary introduction to science means that metascientific questions are viewed from a different perspective. There is, in addition, a welcome historical dimension introduced through case-studies, those commodities which are always so eagerly sought by teachers of science studies. As with the other two books it would be possible to direct students to specific sections rather than treat the text as a whole. Indeed, some selection of material is probably inevitable since few science studies teachers have sufficient time at their disposal to permit more than a sampling of the range of topics introduced in the three books, let alone persuade students to read into the chosen areas as suggested. Stimulating as these guided tours may be, the problem remains of translating them into the one or two hour a week teaching session typically allowed for such studies in the science curriculum. □

nature

NATURE VOL. 314 21 MARCH 1985

Etiquette for arms control

Politicians in the United States and the Soviet Union have a serious responsibility towards the arms control negotiations at Geneva — they must keep more quiet than is their habit.

THE best news from Geneva last week is that there was very little of it. Too many earlier conferences on arms control have been ruined by the recklessness of senior politicians on one side or the other in taking it into their heads to utter public statements about the course of the negotiations. Sometimes they have even advertised their "negotiating position" before letting the other side know privately what they have in mind. When people spill the beans like this, they often believe they are acting sensibly. The motive in going public is usually that such a step will strengthen the hands of negotiators operating behind closed doors, if only by reducing their freedom for manoeuvre. The difficulty is that successful negotiations demand a degree of flexibility, not to be mistaken for a readiness to compromise on issues of principle. In negotiations like that now begun at Geneva, the slow and inevitable leakage there will be about the conduct of the argument is immaterial. What will be damaging are statements made in public outside the negotiations which are intended to influence their course, or which declare that the outcome (whatever it may be) will be of no importance. Let us hope that there will now be a moratorium on public speaking.

Keeping quiet will be harder for the United States than for the Soviet Union. Constitutional pluralism can be a diplomatic embarrassment. But the United States is also caught up in several nasty almost domestic squabbles about strategic weapons, from Australia and New Zealand to Belgium (where the government's decision to let cruise missiles be installed has lent strength to the anti-nuclear movement). It will not help that the debate continues in the US Congress about the administration's authority to build another clutch of MX missiles. On past form, it is almost certain that some administration official will be tempted to go imprudently far, and in public. It is ironical that the dangers of the MX debate would be lessened if the United States were only to recognize that, even on military grounds, the MX is a mistake. It is too big and clumsy, and carries so many warheads that its deployment will entail putting too many eggs in too few baskets. (Each missile that fails on take-off will presumably have to be replaced by another, kept waiting in the wings.)

The Soviet Union, where plurality is not conspicuously a problem, is more strongly based. Mr Mikhail Gorbachev's accession may even help, by allowing subtle changes of policy seem less like concessions to pressure from outside. For what it is worth, the Soviet Union has, in any case, recently abated its earlier fierce complaint about the star wars issue. Condemnation of the idea persists, of course, and Soviet spokesmen keep saying there can be no agreement at Geneva without an agreement on the "demilitarization of space". That is legitimate enough, although the point has been made so often that it should now be repeated only in private (at Geneva). But the demand, loudly heard six months ago, that there should also be a moratorium on the testing of components of a space-based strategic defence has been quietly dropped. (A moratorium on the testing of anti-satellite weapons is a different issue, and would be valuable in its own right as well as an aid to a successful negotiation.) Temptations to speak out unwisely will nevertheless, no doubt, arise.

Meanwhile, both sides at Geneva are saying that the negotiations will take time, but that they could in the end succeed. That they take a longish view is a welcome sign of realism. But it would have been more encouraging if the two sides had settled for a more empirical way of working, one that did not require that success should hang on a solution of all the world's problems at one stroke. For most people, a few modest steps towards a more comprehensive agreement would be preferable to the promise of an all-embracing agreement that could be snatched away by the simplest failure during the next few years. Conversely, a few modest agreements now — why not settle for ratifying the unratified treaties on the threshold test-ban and peaceful nuclear explosions? — would give the negotiators time to tilt at the big windmills.

The most obvious weakness of the arrangements on which the two sides at Geneva have agreed is that success hangs critically on success in each of three parallel sets of negotiations, on missiles of long and intermediate range and on star wars. The linkage between the first two issues is natural, given the strategic interest of Western Europe and other regions of the world, but star wars is logically separate, at least now. (Further ahead, it the United States had a working missile defence, the Soviet Union would be forced to build more missiles or to do something else.) The haunting difficulty is that if star wars had never been conceived, the missile negotiations would now be just as difficult as those that aborted at Geneva at the end of 1983. Is it not asking a lot, to hope to succeed now in an all-embracing negotiation when there was only failure to report in the simpler circumstances of eighteen months ago? After so much disappointment, why do the arms control diplomats allow themselves to be frustrated by the over-ambitious goals they set themselves?

To the errors of garrulity and over-expectation that repeatedly catch out the practitioners in this esoteric trade must be added a third — poverty of imagination. When arms control negotiations between the superpowers began, nearly thirty years ago, it was customary for the practitioners to try to visualize how things must seem to their opposite numbers, on the other side of the table. The view "from over the hill" was the standard phrase. That exercise seems to have lapsed. And both sides are to blame.

The Soviet Union, for example, has been inscrutably insensitive to the West's perception of its development in the strategic field. The large increase in the numbers of SS20 missiles (which have intermediate range) deployed in Western parts of the territory during the past ten years is shrugged off as if it were irrelevant to the strategic balance in central Europe. More recently, the phased-array radar that has popped up in Siberia, apparently in violation of the anti-ballistic missile treaty, went unexplained for more than a year and was then passed off as a component of a space-tracking network, as if there is nothing more to be said (or asked) about this installation. No doubt developments of a political character are even more unsettling of opinion over the hill. As things are, it must be assumed that the Soviet Union has given up trying to anticipate the impressions its actions cause.

The same, unfortunately, seems to be true of the United States. Nobody seems to have invited President Ronald Reagan to consider how the frequent claim that star wars (or authority for MX missile building) has forced the Soviet Union "back to the negotiating table" must seem inside the Soviet Union, habituated to the notion that the world is against it and now economically insecure as well. The claim, often heard, that the Soviet Union

has no business to react so angrily to star wars because its potential for making a first strike from the West feasible is a strictly academic matter, given that the United States would never do such a thing, must sound disingenuous in places such as Omsk and Novosibirsk. Even the assumption, commonly voiced in the United States, that the superior high technology of the United States (in the civilian field at least) will always ensure success in an arms race, may sound aggressive in the East. So should not Western politicians, like those elsewhere, learn not merely to hold their tongues for the duration of the Geneva negotiations, but also spend a little of the time they will save trying to see things from the other fellow's point of view? □

Hearts in the wrong place

The unauthorized use of an artificial heart in Arizona was mistaken humanity.

NATURAL sympathies are with the Arizona surgeon who two weeks ago commandeered an unapproved artificial heart in an effort, ultimately futile as it happened, to keep his patient alive while a replacement human heart could be found. The surgeon, Dr Jack Copeland, has been cast in the traditional American role of the rugged individualist defying authority to do what is right. The Food and Drug Administration (FDA) has obligingly filled in with the part of the pointy-headed bureaucrat by mumbling about technical violations of regulations.

The facts of the case are these: a 33-year-old man who had had two heart attacks and a poor chance of living much longer was given a new human heart in what is becoming an increasingly routine operation. The new heart, however, stopped beating the next day. While Dr Copeland began the search for a replacement, the patient was placed on a heart–lung machine. As the hours passed — and a patient can be kept on the heart–lung machine only a few hours before his red blood cells begin to be damaged — Dr Copeland decided the only hope for his patient was the temporary implantation of a mechanical heart.

FDA had authorized only one surgeon — Dr William DeVries of the Humana Heart Institute in Kentucky — to perform that procedure, and only with the Jarvik-7 heart, which was developed at the University of Utah. For reasons that are still unclear, Dr Copeland called St Luke's Hospital in Phoenix, and asked surgeons to bring a mechanical heart under development there. That heart, developed by a dentist, had not been submitted to FDA for approval. It had never been used in a human. Its longest test had been in a calf, for 12 hours. (The Jarvik heart was tested for months in a calf before the first clinical test.) A Jarvik-7 heart was flown in as well, but was not used; some reports say the University of Utah decided against participating in the unapproved surgery.

The Phoenix heart kept Dr Copeland's patient alive for 121 hours; a new human heart was then transplanted but by then lung damage had taken its toll and the strain on the new heart was too much. The patient died, three days after the ordeal began.

Dr Copeland and his surgical team say, simply, that there are higher laws than FDA when a patient's life is at stake. Yet the very point of FDA's regulatory role is to prevent the sort of haphazard and unplanned experiments on humans that in fact took place here. Informed consent — which was obtained from the patient's relatives — is only one necessary element in assuring the ethical practice of experimental medicine. In a crisis, what relative is going to say no to a doctor, especially one so obviously sincere as Dr Copeland in wanting to do the best for his patient? It may be a cruel thing to say, but the end result of what happened in Arizona is that a human being was used as a guinea pig. The FDA rules, hardly extreme, are designed to assure a minimum degree of safety and likely benefit before humans become the experimental subjects.

The irony of the entire episode is that, with better planning, what was attempted at Arizona is really the way that artificial hearts ought to be put to use now: as a stop-gap during heart-transplant surgery. After the Arizona episode, FDA did in fact approve yet another artificial heart — this one developed in Pennsylvania — for just this purpose. Heart transplants can now offer real hope for otherwise hopeless patients. They have also succeeded in many cases in allowing patients to resume near-normal, active lives. The same simply cannot be said for the "permanent" implantation of artificial hearts at this primitive stage of development. An implant that must be tethered to a huge external air compressor (apart from posing a constant risk of infection at the point where the tubes enter the patient) exacts a devastating psychological toll.

The argument, of course, is that the early heart transplant operations could have been criticized on similar grounds — that they were grandstand medicine, more stunts than attempts to improve the patients' well-being — but that what was learned in these many early attempts paved the way for today's successes. The analogy is not exact, however. The medical spectaculars at the Humana Heart Institute (which has permission from FDA to go ahead with more "permanent" artificial heart implantations) are turning out to be gruesome endurance tests. No matter how much is learned about surgical technique, proper medication and the like from these operations, the technology of the heart itself is simply too primitive to justify the goal of permanent implantation. They are attempting to fine-tune a procedure that is questionable even if it worked perfectly.

Admittedly, clinical performance data need to be collected hand-in-hand with efforts to improve the technology. But limiting the artificial heart to temporary use seems a reasonable compromise to achieve this goal without turning humans into guinea pigs. □

Sustaining Africa

The UN now has money with which to feed Africa. How should it be spent?

THE United Nations has surprised itself by collecting (in promises) more than twice the $1,000 million it had asked for so as to reinvigorate African agriculture. No doubt part of the success stems from this season's appalling famine in Ethiopia, worse than last season's by a long way if only because it was more elaborately covered by television cameras. Unfortunately, it is far from easy to tell how such large resources could be spent wisely and quickly enough to make much difference within the lifetime of those who have worked to recruit the funds. The temptation will be to spend the money on the classical agricultural projects of development — irrigation dams and drainage schemes. But the needs are social and even political.

Ironically, most industrialized countries honour their farmers and are indeed over-generous towards them, but developing countries, where the need for food is greater, tend to worry instead about the prices that urban people (and voters) pay for the food they eat. The result is price control that pauperizes the farming population, driving them to the cities to look for welfare instead of growing food. On many occasions, matters have been made worse by spectacular mismanagement, as of Ghana's cocoa crop, once the foundation of the country's relative prosperity. In Ethiopia, part of the cause of this year's famine must be the hostility of the government (and, fair play, of the farmers) towards the middlemen who traditionally bought grain from farms and sold it on to cities; nobody remembered that the middlemen were the distribution system, which collapsed when the intermediaries were abolished. There are also, of course, climatic and agricultural problems of great severity.

The most urgent need, and the best use of the UN money, is for a technical infrastructure to support peasant agriculture, Africa's equivalent of the extension services of Europe and North America (but also in place in India before the green revolution). The second need is for better plant breeding, done in Africa (but not necessarily by Africans.) The third is that African governments should recognize that the whole country will go hungry if farmers are driven to starvation by low prices. There might even be some change left over for a few dams. □

Genetic engineering patents

Contest in prospect over interferon rights

Washington

BATTLE lines are now being drawn up in what may be the first major contest for patent rights over a commercially significant product of genetic engineering.

The product, human leukocyte (alpha) interferon, has shown potential in clinical trials against some cancers and viral diseases, including the common cold. Last year Biogen NV of Cambridge, Massachusetts, and Geneva, Switzerland, announced it had received a European product patent for alpha interferons produced by recombinant DNA techniques; the company expects shortly to be issued with a US patent covering the same claims. Now, however, Hoffman-LaRoche Inc. of Nutley, New Jersey, has announced that it has received a US patent covering "all highly pure human leukocyte interferons no matter how they are made". John Saxe, chief patent counsel for Roche, says the company is "not aware of any highly pure leukocyte interferon product that does not fall within the issued claims". Schering-Plough Corporation, which produces Biogen's interferon (trademarked Intron) under licence, immediately challenged Saxe's claim, denying that Intron fell within the scope of Roche's patent.

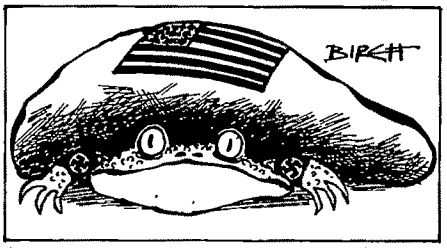
The Roche patent is based on the 1970s work of Sidney Pestka and Menachem Rubinstein, in which they isolated and purified alpha interferons from human cells. LaRoche expects to receive a further US patent covering its own recombinant alpha interferon, Roferon-A, which was developed in collaboration with Genentech Inc. of San Francisco. The patent already issued to Roche defines interferon by its anticytopathic activity as assayed by two standard cell lines but does not include sequence data; Biogen's European patent, in contrast, does specify the product by sequence. A further complication is that Biogen's patent, which was filed before that of Genentech/Roche, strictly refers to an interferon precursor molecule, not the mature molecule, according to Genentech.

Alpha interferon is undergoing clinical trials at several centres in the United States. Diseases in which it has shown potential include Kaposi's sarcoma (often associated with acquired immune deficiency syndrome), multiple myeloma, malignant melanoma and hairy cell leukaemia. Both Schering-Plough and Roche have submitted marketing applications to the Food and Drug Administration for their respective products, which differ by a single amino-acid residue. Schering's Intron is approved for use in two indications in Ireland and the Philippines.

The courts have yet to test patent law as applied to genetic engineering products, and many small companies are seriously concerned that their product options might be constrained by broad product patents. Both Schering-Plough and Roche, as major corporations, have the resources to endure a court battle should one become necessary: Peter Feinstein of Biogen says he is confident that Schering will be able to prevent Roche from marketing Roferon-A. But industry analysts point out that large pharmaceutical corporations tend to avoid court cases wherever possible, and some sort of compromise may yet be negotiated.

Whatever the resolution of the present dispute, it is unlikely to serve as a model for future cases; with each product patent issued, the extent of "prior art" increases and future patents become harder to defend. One possible pointer to the future, however, is the recent US patent granted to Cetus Corporation covering what it calls muteins of interleukin-2, a lymphokine with anticancer and antiviral potential. The muteins are specific modifications of the natural protein: the Cetus mutein is claimed to be more stable than natural interleukin-2. Just as important, however, Cetus is confident that its mutein will lie outside the scope of other interleukin-2 patents.

Tim Beardsley



Military manoeuvres

Scientists' Nazi past laundered

Washington

US ARMY intelligence officers deliberately altered the dossiers of German scientists brought to the United States at the end of the Second World War to conceal their Nazi party activities and, in some cases, even their indictments for war crimes. Government documents released for the first time leave little doubt that the Army's intention was to circumvent President Truman's order that no "active supporter of Nazism or militarism" be allowed into the country under the programme of recruiting German "specialists".

Among those whose dossiers were altered was Wernher von Braun, the rocket scientist who later assumed a leading role

in the US space programme. Von Braun's original dossier labelled him a "potential security threat".

The Army also attempted to recruit four scientists who were later indicted at Nuremberg for war crimes. One was sentenced to 20 years' imprisonment for participating in experiments in which concentration camp inmates were forced to drink sea water.

The documents, which are the first to show a deliberate cover-up by the Army, were obtained by a reporter for the *Bulletin of the Atomic Scientists* under the Freedom of Information Act. A full account will appear in the April issue of the *Bulletin*.

Under President Truman's order, the State Department had to pass on scientists recruited by the Army. In early 1947, the State Department refused visas for several scientists labelled in security reports as "ardent Nazis". The director of the recruitment programme, Bosquet Wev, then complained to the Army's intelligence director that "the best interests of the United States have been subjugated to the efforts expended in 'beating a dead Nazi horse'". Wev said "the most positive and drastic action" was needed. The most revealing document came later that year: Wev again wrote to Army intelligence, and enclosed dossiers of 14 scientists, including von Braun: "...security reports recently forwarded from your headquarters classify 14 specialists as potential or actual threats to the security of the United States...there is very little possibility that the State and Justice Departments will agree to immigrate any specialist who has been classified as a...security threat...It is requested that the cases of the specialists listed in paragraph one be reviewed and that new security reports be submitted where such action is deemed appropriate in view of the information submitted in this letter." All were subsequently changed.

Other dossiers — such as those of the scientists indicted at Nuremberg — appear to have been "clean" from the start. The dossier of Arthur Rudolph, the NASA scientist who left the United States last year to avoid being deported for his role in the persecution of slave labourers at the V-2 rocket plant that he managed during the war, made no mention of evidence from the Nuremberg trials implicating Rudolph nor of his having joined the Nazi party in 1931.

All told, 765 scientists and technicians were recruited under the programme. The documents confirm that a major concern of the US officials who ran the programme was not letting the German scientists fall into Soviet hands. Wev wrote in one memorandum: "The return of these scientists to Germany would present a far greater security threat to the United States than their retention in this country".

Anthropology

Genetic links for scattered Jews

Rehovot

PRELIMINARY studies using DNA sequences as a new and sophisticated tool for genetic analysis tend to support the conclusion drawn from earlier investigations that the Jews, even after being scattered around the world for two millennia, remain — to a significant degree — genetically distinctive.

This view, propounded for many years by Professor Batsheva Bonné-Tamir from the Department of Human Genetics at Tel Aviv University's Sackler School of Medicine, has met with opposition from some other scientists who use different statistical methods and from those who feel that any attempt to suggest the existence of a specific Jewish group is to be rejected as racist doctrine. Professor Bonné-Tamir is obviously not a proponent of such a doctrine, nor does she suggest that the Jews are better or worse for having a common genetic heritage. She simply points to the evidence that it exists.

Among the genetic markers used in the past by Professor Bonné-Tamir are blood types, enzymes, serum proteins and histocompatibility antigens (see *American Journal of Human Genetics* **34**, 50; 1982). The new data, which have been submitted for publication, come from the most direct genetic measure — that of DNA sequences, in this case of short stretches of mitochondrial DNA. But whatever the criterion, she and Professor Samuel Karlin of Stanford University in the United States find that Jews from Iraq, for example, have far more in common from a genetic viewpoint with Jews from Poland than either group has with the non-Jews among whom they have lived for centuries. This is also true of immigrants to Israel from such diverse areas as Germany and the Soviet Union on the one hand and Libya on the other.

It has become possible to make more revealing comparisons between Jews and non-Jews in recent years because of the increasing number of genetic studies on both.

There are, it seems, a few exceptions to the general picture of relative Jewish distinctiveness. Jews from Yemen, often popularly regarded as the Jewish group that looks most "biblical", are a case in point. "They have a genetic make-up", Bonné-Tamir reports, "that is characteristic of the Saudi-Arabian peninsula and are probably the descendants of indigenous tribes which converted to Judaism in the fourth and fifth centuries."

A similar situation prevails in regard to Cochin Jews and the local Kerala Indians, communities that are genetically linked to one another but have little in common, from a genetic viewpoint, with other Oriental-Jewish groups or with non-Jewish elements in southwest Asia. This fits in well, Professor Bonné-Tamir points out, with the theory proposed by Professor Avinoam Adam of Everyman's University (Israel's equivalent of the UK Open University), who has written: "in some areas and during some specific periods, the Jewish religion expanded much faster than Jewish genes".

Most timely of all, in view of the present wave of immigration from Ethiopia, are her findings about the Jews from that country. Various theories exist as to their origins, with members of the community itself tending to argue that they are descendants of the tribe of Dan (one of the original 12 tribes of the Bible) and/or of ancient Jewish communities in Upper Egypt that moved south. Yet after studying representatives of a hundred immigrant families from Ethiopia, Professor Bonné-Tamir comes to the conclusion that genetically they most resemble the Amhara tribe, and to a lesser extent the Billen and Tigre tribes, of Ethiopia. But she says "there is no denying the fact that the Yemenite, Cochin and Ethiopian Jews have long displayed strong emotional bonds with Judaism and rushed to join their co-religionists in Israel as soon as they had the opportunity to do so."

Nechemia Meyers

Australian technology

OECD begs leave to differ

Canberra

AS soon as the Organization for Economic Cooperation and Development (OECD) draft report on the state of Australian science and technology was made available last month, it became obvious that many of the recommendations for improvement were exactly the opposite of those in operation at present or likely in the near future. The examiners asserted that it was essential that the science and technology portfolios be combined and represented at Cabinet level by a strong minister. An Australian federal election was held between the first draft of the report and its submission to the Australian authorities, the upshot of which was a portfolio reshuffle, splitting Mr Barry Jones's Department of Science and Technology, with politically important policy sections being absorbed by Senator John Button's Department of Industry and Commerce (see *Nature* 5 January, p.4). Mr Jones's remaining Department of Science has in the meantime been casting about for new vistas in science without technology, a condition described by the examiners as "perverse", because, in their view, the topics are so completely interwined. The government's action also puts paid to the examiners' recommendation that the Australian Science and Technology Council (ASTEC) should report to a "strong science minister" rather than supply policy advice directly to the Prime Minister, which has been its brief since 1976.

The difficulty is the notion of a single strong minister for science and technology. Senator Button certainly fills the bill for his now-extended Department of Industry, Technology and Commerce, but part of the reason for the political downgrading of Mr Jones's portfolio was his unwillingness to linger in smoke-filled rooms where the deals are done. It is difficult for citizens of nations where science and technology are not (yet) an issue to appreciate the job of advocacy that Mr Jones has done in Australia, and the void that existed before him. The examiners noted that many of the depositions submitted to them in the course of the study bore witness to the discussions he had sparked in 1983-84, but something else shone through as well: a sense that science and technology were somehow external to national life and that the transition from research to design and sales of a product seemed to involve the collision of mutually uncomprehending cultures.

Part of this they attributed to the education system and recommended (*inter alia*) that research in universities and other tertiary institutions be strengthened, especially by the purchase of modern equipment, both propositions unlikely in the short run, given the Treasury's present parsimonious mood. The examiners supported some tactics — such as manpower planning — that are unlikely to find favour, and suggested that Australia should not follow blindly the example of other countries in developing "key technologies" such as information technology and biotechnology, but instead examine its own latent strengths on a sectoral basis, suggesting pharmaceuticals as a possible new industry. Whereas in the past Australia has used bounties and tariffs to shore up industry rather than the system of fiscal incentives common in other OECD countries which encourages business enterprise to classify its activities as research and development for tax purposes, the examiners recommended that tax-based schemes be instituted in Australia, a strategy the government has already begun and may expand.

Although preceded by an OECD *rapporteur* a year ago, the examiners themselves spent only one week in Australia. Inevitably, their report must be coloured by views expressed in the submissions made to them. They seem awake, nonetheless, to the pressures that have been brought to bear on OECD referees in the past, noting that familiar arguments about the economic benefits of investment in intellectual and technological infrastructure may be needed for the benefit of the Commonwealth Department of Finance. A final consultation and draft are due later this year.

Jeffrey Sellar

Soviet policy

Gorbachev on science

SOVIET scientists, and, indeed, Soviet society at large, must pay greater attention to the challenge of modern technology, according to the new General Secretary of the Communist Party of the Soviet Union, Mikhail Gorbachev. Addressing the Central Committee last December, in place of the ailing Konstantin Chernenko, Gorbachev noted that although in many enterprises and scientific institutions research and development problems are resolved "up to the standards of the world's top achievements", many "collectives" are still satisfied with repeating what has been outstripped in world practice.

Paramount importance, Gorbachev told the Central Committee, must be attached to the strategy for developing scientific, technical and production potential, and, in particular, to "fundamentally new and really revolutionary scientific and technical solutions" which will increase labour productivity many times over.

This has been standard party policy for some time; what is, perhaps, significant is Gorbachev's emphasis on the idea that scientific and technological progress can be achieved only by raising the "cultural and technical standard" of the working class and peasantry, and "a radical improvement in the training and perfecting of society's main productive force". This, he said, will entail a major restructuring of the "cadre training system" at all levels of education from primary school up to university. This work is already under way, he noted, but "must acquire a large-scale character".

Educational reform, in particular the changes introduced in September 1984, is apparently a subject in which Gorbachev takes a special interest. One of his last major engagements before his elevation to the general secretaryship was to chair a meeting of the Commission on the Reform of General and Vocational Education. The 1984 reforms stress "practical labour training, and vocational orientation" for all school-children, and the appropriate production ministries are expected to help provide necessary facilities. The February meeting of the commission, however, found that the All-Union Ministry of Light Industry and a number of light industry ministries in the union republics have in many cases contented themselves with drawing up "plans for measures and instructions". Local government officials and education committees, likewise, have been doing little to implement the reform.

This slackness, the commission decided, will not do. Within the next two to three years, it warned, all school-children must be properly involved in socially useful and productive labour, and at the same time, all secondary-school pupils must be computer-literate. **Vera Rich**

Bendectin/Debendox

Drug not guilty, says court

Washington

A FEDERAL jury last week decided that there is no evidence to link Bendectin, an antinausea drug used in pregnancy, and birth defects. The court, in Cincinnati, Ohio, dismissed a case brought by 1,100 women across the country, representing two-thirds of outstanding US claims against Merrel Dow pharmaceuticals, the maker of the drug.

A spokesman for the company said the decision established that a product liability case could be successfully defended in the United States and indicated that Merrel-Dow will now be in no mood to propose no-liability settlements in the remaining cases. Earlier, the company had offered $120 million in settlement of all outstanding and future claims.

Bendectin (known in the United Kingdom as Debendox) was available as a prescription drug in the United States from 1956 to 1983, when it was withdrawn by the company because of high insurance premiums resulting from the accumulating claims and the bad publicity. Merrel Dow says that no fewer than 27 epidemiological studies have failed to turn up any evidence that the drug causes birth defects. The active ingredients are doxylamine (an antihistamine) and vitamin B6. Before 1976, Bendectin also contained dicyclamine, which was removed because of insufficient evidence that it added to efficacy.

The Cincinnati ruling is the third courtroom vindication for Merrel Dow. A case in Florida in 1981 was decided in the company's favour; in 1983 a jury in Washington DC awarded one plaintiff $750,000 damages but was overruled by the trial judge. The publicity made Bendectin a potential bonanza for tort lawyers, some of whom started to advertise for parents of children with birth defects who might have been affected by Bendectin.

Recognizing that the mass of litigation threatened to clog the legal system, the trial judge in the most recent case took the innovative step of holding a common issues trial to decide questions relevant to all the 1,100 plaintiffs. In an attempt to avoid having to face future litigation on Bendectin, Merrel Dow offered $120 million as a class settlement to cover all future claims. The offer was accepted by the majority of attorneys in the case but was challenged by some dissidents; the class settlement was then disallowed by an appeal court on a technicality, necessitating the trial that ended last week. **Tim Beardsley**

Soviet Union

More nuclear research

THE Dubna Joint Nuclear Research Institute in the Soviet Union is to expand its area of research considerably during the coming five-year plan (1986–1990), its director, Academician Nikolai N. Bogolyubov, announced last month. Addressing a meeting of government plenipotentiaries of the 11 member states of the institute (the 10 Comecon partners plus North Korea), Bogolyubov noted that during the next five-year plan "great attention" would be paid to identifying applied work, using the results of fundamental research in related spheres of science and technology, in particular medicine, geology, biology, metallurgy and ecology.

Applicability of fundamental work is a keystone of Soviet science policy, and in a formal keynote speech need not have anything other than a purely ritual significance. Bogolyubov, moreover, has a background in fundamental mathematics and physics and has just been awarded the Lomonosov medal, the highest honour of the Soviet Academy of Sciences, for his theoretical work. Nevertheless, at a time when Comecon research plans in all fields are being closely coordinated, the commitment of Dubna to finding new applications for its research probably represents a genuine statement of intent, especially for the less prosperous member countries.

In his speech, Bogolyubov put considerable emphasis on the "powerful experimental base" that Dubna has acquired in recent years, including the "unique" pulsed neutron fast reactor which came into operation last year, and the plans for the construction of a nucleotron — a superconducting accelerator with the aid of which, he claimed, it will be possible to accelerate nuclei of virtually all the elements in the Mendeleev table, right up to uranium. Dubna's latest achievement, announced shortly before the February summit, also lies in the theoretical field: the creation of element 108. According to the official announcements, in the spring of 1984, in work on the new U-400 cyclotron at Dubna, 44 cases of the decay of three isotopes of element 108 were recorded.

In spite of the "experimental base" praised by Academician Bogolyubov, however, not all is well at Dubna. The central computer centre, in particular, seems to be inadequate, judging from the stress placed on the need to enlarge its capacity. The "instrument centres" of the various laboratories, too, need to be expanded.

● The Soviet Union, of course, has other atomic research institutes. Foremost among these is the Kyrchatov Institute of Atomic Energy in Moscow which, says Academician Evgenii Velikhov, has a considerable lead over the West in fusion research. **Vera Rich**

CERN

How to pay British share

BRITISH Foreign Office subscriptions to international bodies are effectively protected against exchange rate fluctuations by the Treasury — so why should not the international subscriptions of the Science and Engineering Council (SERC) be similarly protected? Two Oxford high-energy physicists, Professor Don Perkins and Dr John Mulvey, have put this question to their local Member of Parliament, Tory John Patten, who has promised to raise the matter with Sir Keith Joseph (Secretary of State for Education and Science). Sir Keith is still awaiting news from the Kendrew committee on Britain's future role in high-energy physics, so the physicists' intervention is opportune. Friction between high-energy physicists and others supported by SERC, which pays the annual subscription to CERN (the European Organisation for Nuclear Research), is exacerbated by the fluctuating cost of the subscription in pounds sterling against what is now a constant subscription in Swiss francs, and any realistic way of handling the fluctuations would at least ease tempers.

According to Perkins and Mulvey, the issue is this. Member states of CERN pay their subscriptions in Swiss francs according to their "net national income" (NNI) averaged over three years. The proportions are determined every three years using the most recent statistics of the United Nations Statistical Office. But these statistics can be three years old, with the result that actual payments can be six years out of line with real current NNI. "For example, the present shares were decided in 1983, using data for 1979-81. They will be in force for 1984-86."

Nevertheless, in the long run, exchange rate fluctuations are automatically corrected, as NNIs are calculated in dollars. So if sterling falls the British NNI falls with it. But the delay in calculations causes trouble. Recently, the sterling cost of the CERN subscriptions has risen sharply from £23 million in 1981 to £35 million in 1984 because sterling, and hence NNI, was strong against the dollar in 1979-81 but has fallen nearly twofold since.

According to Perkins' and Mulvey's calculations, the net overspend (out-turn minus estimate) by SERC on the CERN subscription over the eleven years starting 1971-72 was only £4.75 million (just over one per cent of the total). From year to year, however, the overspend has been as high as £4.5 million (1976-77) and as low as minus £8.7 million (1980-81) — a profit for SERC.

"Exchange rate and relative NNI changes are quite outside the control of anyone", write Perkins and Mulvey, "and the application of 'cash limits' (inclusive of the international subscriptions) to the already desperately strained SERC budget does not encourage economy. It only subjects the scientific programmes to arbitrary jolts which have very damaging, and wasteful, effects."

Thus they recommend:

- That subscriptions to international research organizations (such as CERN) should remain part of the budget of the appropriate scientific policy-making body (for example SERC). "Then the trend of the budget... can be decided in the right scientific context."
- That the delay in the calculation of relative contributions be shortened, "though this may not be welcomed by countries with more stable currencies".
- That SERC could pay foreseen subscriptions in sterling, while the Treasury corrects for changes in the exchange rate and NNI by adding or subtracting the appropriate sums. "This separates the functions of making scientific policy (SERC) and solving the technical problems (Treasury).... Experience shows that the Treasury (and SERC) would not lose (or gain) over a number of years."

Moreover, Perkins and Mulvey claim, "there can be no objection in principle to such a mechanism since cash limits are not applied to the international payments made by the Foreign and Commonwealth Office".

Here, however, there appears to be some uncertainty. According to a Treasury spokesman, Foreign and Commonwealth Office (FCO) international subscriptions (to the United Nations, for example) are indeed not cash limited, which means that the Treasury will bail out FCO if there are political changes in those subscriptions during a financial year, but on currency fluctuations, FCO must look for "offsetting savings", according to the Treasury. However, unlike SERC, FCO has a long-standing "arrangement" with the Treasury by which the fluctuations are discussed as they occur. **Robert Walgate**

NSF deputy at last

DR John H. Moore, an economist at the Hoover Institution in Stanford, California, has been nominated by President Reagan to be deputy director of the National Science Foundation (NSF), a post that has been vacant for two years.

Although Dr Moore has an undergraduate degree in chemical engineering and worked as an industrial research chemist for four years, his PhD is in economics, a subject to which he has devoted the bulk of his professional career.

Moore has been a member of the National Science Board, NSF's formal governing body, for the past two years.

The Hoover Institution is a generally conservative think-tank associated with Stanford University. □

Archaeopteryx

Fraudulent feathers?

SCIENTISTS at the British Museum (Natural History) met on Monday to launch their response to the mounting publicity surrounding the claim by Lee Spetner in Rehovot and a group including Fred Hoyle and Chandra Wickramasinghe from University College Cardiff, that the feather impressions on their specimen of the famous fossil bird-like reptile *Archaeopteryx* may be a fake.

The controversial claim has been raised by an editorial and an article accompanying new photographs of this specimen published by the group in the *British Journal of Photography* two weeks ago. The crux of the claim is that many of the feather impressions occur on patches of material that are much finer-grained than the underlying rock and in parts the material looks like "flattened blobs of chewing gum". The possibility is that this represents some sort of cement that was applied to the fossil after discovery, on which feather impressions were made.

To elevate the argument from rhetoric and refutation, the scientists at the museum decided at their meeting to carry out two tests on the fossil specifically to address the possible existence of a cement layer. They will first take a section of material from the edge of the specimen for standard microscopic sedimentational analysis to detect any differences in particle size and the existence of a boundary between a surface layer and underlying material. They will then use electron microprobe analysis to compare X-ray spectra emitted by surface and underlying material.

The team is not, however, optimistic that these tests will provide clear-cut evidence and is already aware that a cement made from underlying rock might not be detected by these analyses. Although ready to carry out these tests immediately, the team feels it may be best if the areas selected for analysis are chosen by Hoyle's group.

The decision to allow samples of material to be taken from this extremely important fossil results from the conviction, voiced by Dr Alan Chong of the Department of the Palaeontology at the museum, that the specimen is genuine. He would seem to have considerable support from the existence of five other specimens assigned to *Archaeopteryx* from the Upper Jurassic. All have associated feather impressions but were discovered at different times and at different sites. Indeed, the incomplete Tyler specimen discovered in 1855 was first described as a pterodactyl, and it was not until 1972 that John Ostrom noted the feather impressions and described it as *Archaeopteryx*. If the feather impressions are the work of a single faker, he must have been remarkably fleet of foot and very prescient. **Nigel Williams**

Genetic diseases

Problems of prenatal testing

Washington

NEW techniques for prenatal diagnosis of genetic diseases are sharpening the debate in the United States over when the Food and Drug Administration (FDA) should approve for commercial use test kits that might lead a woman to prefer an abortion to the possibility of bearing a handicapped child. Methods based on analysis of fetal DNA promise to increase greatly the number of diseases for which prenatal diagnosis is possible, but the anti-abortion lobby is firmly opposed to any test used in a "search and destroy" mission. And the anti-abortion lobby cannot be dismissed as part of the lunatic fringe: President Reagan has made clear his opposition to abortion under any circumstances.

Prenatal testing for some easy-to-detect conditions such as Down's syndrome and Tay-Sachs disease has been carried out for several years. Although in some instances a good argument can be made that tests have increased, rather than decreased, births of healthy but potentially affected children, the strength of anti-abortion sentiment suggests that the arguments will have to be fought anew as each new test becomes available. Furthermore, the spread of chorionic villus testing, which allows fetal cells to be obtained earlier in pregnancy than by amniocentesis, could make easier those abortion decisions based on tests for inherited conditions: the National Right to Life group is already challenging use of the technique.

FDA spokesmen are wary of speculating about the regulatory passage of future commercial kits, but it is clear that any company wishing to market a new prenatal diagnostic will have to go to unusual lengths to provide data on false positive rates before approval can be expected; a false positive result could lead to the unnecessary abortion of a healthy fetus. Industry spokesmen hope that FDA will restrict itself to questions of safety and efficacy, disregarding the thorny risk/benefit issue, with its attendant questions about the quality of life of a handicapped child. But some recent FDA decisions — on putative cancer therapies, for example — suggest that FDA does indeed consider it part of its job to scrutinize possible benefits as well as safety.

In 1983, after seven years of foot-dragging, FDA eventually approved unrestricted use of test kits to detect elevated concentrations of α-fetoprotein (AFP) in amniotic fluid or serum, indicative of neural tube defects such as spina bifida. That decision reversed FDA's earlier position, in which it had sought to specify the testing protocol and interpretation of results for AFP kits. Although it is pointed out in defence of FDA's delay that there are good reasons to be wary of uncritical use of AFP tests, few tests would claim to be 100 per cent efficient — in any case, numbers matter little to those whose opposition to abortion is based on religious grounds; it remains to be seen whether future tests will experience similar delays.

Many prenatal diagnostic tests, such as those for sickle cell anaemia and phenylketonuria, are now being performed in university medical centre research programmes, approved by institutional review boards but not by FDA for unrestricted use. Commercial reference laboratories, in contrast, use only FDA-approved reagents. The limits of FDA's authority to regulate experimental tests are "somewhat cloudy", according to an official in FDA's compliance division: although there is no question that an experimental test can be used for evaluation in conjunction with an established technique, or if it presents no significant risk, established tests are sometimes lacking, and abortion decisions are being taken on the basis of experimental tests. There is at least one published case of an abortion resulting from incorrect experimental diagnosis of a haemoglobinopathy.

For some of the genetic conditions that can now potentially be diagnosed by analysis of linked fetal DNA markers, such as retinitis pigmentosa, Duchenne muscular dystrophy and Huntington's disease, testing of relatives is necessary (but not always sufficient) to arrive at probabilistic estimates that a given fetus is affected by an inherited disorder. As long as this sort of specialized knowledge is required for testing, work will be restricted to experimental medical centres and so remain effectively beyond FDA's purview, even though such testing is offered as a commercial service.

But the goal of much current research is to produce probes that will identify a mutant gene directly, or, even better, the gene product. Recently, for example, a direct gene probe for prenatal detection of phenylketonuria has been obtained. When simpler tests become available error rates will fall, and commercial kits will be feasible. One of the greatest hopes is for a test for cystic fibrosis, the commonest lethal genetic disease in the United States. The gene responsible for the disease has not yet been identified, but development of a test is "at an advanced stage", according to Integrated Genetics Inc. of Massachusetts. Although the eventual FDA approval for AFP test kits is hailed as a precedent for future tests, the industry knows that it will have to work harder in future to satisfy FDA demands. **Tim Beardsley**

Geology

New Chinese institute

A NEW Chinese research institute, the Xian Laboratory of Loess and Quaternary Geology (XLLQG), has been set up in Xian, Shaanxi Province. The laboratory is an independent unit, attached to Academia Sinica, and is engaged in the study of the characteristics and formation processes of loess and other Quaternary sediments in China. On the basis of the geological and biological records of the Quaternary period, the workers at the institute will try to reconstruct the history of the environmental changes of the Quaternary, and to understand the effect of human activities on future developments. This reconstruction of the pattern of environmental change is the single most important task facing Quaternary investigators, and those involved with XLLQG will be well placed to make significant contributions.

Xian is in the middle reaches of the Yellow River with the great Loess Plateau and widespread deserts to the north and west. To the east, Xian faces the North China Plain, and to the south, across the Qin Ling mountain, is the Red Basin of Sechuan Province with temperate and subtropical landscapes. The continuous loess-palaeosol series which began to be deposited 2.4 million years ago (see *Nature* **300**, 431; 1982) provides one of the best available indicators of Quaternary climatic changes, and contains abundant traces of early humans and Quaternary vertebrates.

Several research projects are already under way; these include investigations on the composition, physical characteristics and micromorphology of loesses and palaeosols and their relation to environmental changes and engineering construction; processes and mechanisms of recent dust falls and loess sedimentation and the relation of loess accumulation and loess erosion; the evolutionary history of human fossils on the Loess Plateau and the migration of fauna and flora during the Quaternary; loess-palaeosol sequences and their meaning to palaeoclimate since 2.4 Myr BP, and the sequence pattern and its development in northern China; and the recent climatic change (over about the past 2,000 years) and its relevance to human activities on the Loess Plateau and in northern China.

The first director of the new institute is Liu Tungsheng, with An Zhisheng as deputy director. Liu says he expects XLLQG to be a laboratory of international character. It is hoped that scientific and technical cooperation between China and other countries will not be limited to the exchange of research workers, but will also include joint ventures. This idea is fully supported by Academia Sinica and the new institute should provide a chance for investigators from all over the world to work in one of the really classic loess regions. **Ian Smalley**

Radiation data wanted

SIR — In 1975, the International Commission on Radiological Protection (ICRP) published its Publication 23, the Report of the Task Group on Reference Man. Publication 23 is about 15 years out of date, because the references cited end around 1970. At its 1984 meeting, ICRP approved the formation of a new task group to revise and update this publication, with completion expected in about three years.

The revision will include more emphasis on variations due to age, sex and other individual differences in anatomical and physiological data and in the gross and elemental composition of tissues. The emphasis in Publication 23 is on data for radiation workers, and the new emphasis reflects the fact that radiation doses to the whole population are of increasing interest to ICRP and national bodies interested in radiation protection.

The purpose of this letter is to solicit information from users of ICRP Publication 23, incuding workers in the medical and biological sciences outside radiation protection who have used the document. In order that the revised document may be accurate and complete, it is important that we get advice from as many users as possible. The present task group would appreciate hearing about any errors, omissions of important information or shortcomings in Publication 23 or of relevant new data not included.

Please write to the task group chairman at the address below.

Creationism

SIR — As our organization, the Association for the Protection of Evolution (APE), has been accused of misrepresentation and an ethical lapse by Professor E.H. Andrews in his response (*Nature* **312**, 396; 1984) to our report of the Biblical Creation Society (BCS) open day (*Nature* **311**, 703; 1984), we feel obliged to reply. First, if Professor Andrews claims to be a theist, why is he engaged on a project involving natural theological argument and the acquisition of empirical evidence from the natural world for the existence and putative activities of a God — a paradigmatically deistic position implicitly shared by all creationists whether they understand the meaning of the word or not? Second, Mr Malcolm Bowden (for it was he) has on several occasions castigated BCS for its dangerous backsliding tendencies towards the position of theistic evolutionism. Third, Andrews waxes indignant at the suggestion that he has criticized US "scientific" creationism; we need only quote from his seminal article in the BCS "journal", *Biblical Creation* (vol.5, no.16) to show that he has been criticizing US creationism for some time. In this, the first "Biblical Creation Lecture", he writes "the American branch of creationist movement (*sic*) has therefore attempted to develop a scientific creationism that has no religious content". He goes on to say that such creationism involves "a number of very real dangers and problems", is "a-Christian" and "devoid of biblical content". His lecture (which we have on tape) merely amplified his previously published criticisms.

Chris Darnborough was introduced as doing research on genetic engineering and evinced an adequate knowledge of modern genetics, unlike all the other creationists we have so far encountered. APE made a theologically acceptable *in pectoris* decision to elevate Darnborough to the honorary position of BCS's top geneticist in default of any other candidates. The title of his lecture was, after all, "Genes created but EVOLVING" and he did have to apologize to his audience in advance in case they mistook the bulk of his lecture as putting the evolutionist view.

As for APE's "ethical lapse", in reporting Dr Gower, he did indeed state his belief that faults in the perfection of the "design" of the human olfactory organ are due to the effects of the fall of Adam and/or the work of the Devil. Whether he believes this enthusiastically or unenthusiastically is a matter of judgement. Our opinion was the latter. In any event, APE explicitly informed the organizers of the conference that it would be reporting their deliberations for the scientific press.

ALAN J. LEWIS
Cybernetics, Brunel University,
Uxbridge UB8 3PH, UK

SIR — The article "Louisiana law thrown out" (24 January, p.257), described the US court system's rejection of a law that would have required teachers to include "creation-science" along with "evolution-science". The law defined "creation-science" to be "the scientific evidence for creation, and inferences from those scientific evidences". This law required that students be given crucial data, even if they support a theory contrary to the beliefs of the teacher. Teachers who believe the creation account of origins would be required to include the evidence for evolution, just as the proponents of evolution would be required to discuss the evidence for creation. The rejection of this law encourages censorship of data about origins.

The inherent religious nature of *all* versions of origins must not be minimized. It is true that the creation account of origins is consistent with some "theistic religious views". The theory of evolution is consistent with the tenets of non-theistic religions as well as the tenets of the "main-line" and "liberal" churches. All views of origins support someone's religion: there is no religiously neutral theory of origins.

Students have a right to know that the lack of intermediate fossils discredits Darwin's theory of evolution. Students should also be informed that the modern belief in molecular evolution is held in spite of the fact that real observations require the rejection of spontaneous generation. The causes behind the shift in opinion away from creation in the 1850s should be reviewed and discussed with students. The citizens of Louisiana wanted to ensure that crucial data, such as the gaps in the fossils and the Law of Biogenesis, will be part of public school curricula.

The students must be able freely to form their opinions without the fear that critical data have been withheld. It is sad that one federal court and the American Civil Liberties Union seem to disagree.

Missing mass

SIR — I would like to make only a point of general scientific method in reply to your reviewer who found "glaring errors and omissions" in my book *The Hidden Universe* (*Nature* 24 January, p.329).

The book attempts to explain the subject of "missing mass" to the layman. Surely the significant point about this subject is the small but increasing body of observational evidence that has now brought sceptical astronomers round to believe in this phenomenon. The point is *not* the plethora of mythical particles, or other agencies, which can all too easily be advanced to fill up extragalactic space. Precisely because we know so little about the phenomenon, it is of course at present hard to test out the presence there of axions, heavenly chariots or discarded bandwagons. That being so, economy of effort alone directs our attention first to those candidates that are either known to exist, such as neutrinos, or at least lead to some testable predictions. Supersymmetry and GUT [Grand Unified Theory] particles may be appealing to some, while reminding others of epicycles. For the moment, GUTs have fluffed their first proton-decay test, and the fact that they contain 21 readjustable free parameters could be held to lessen rather than add to their appeal in the context of missing mass.

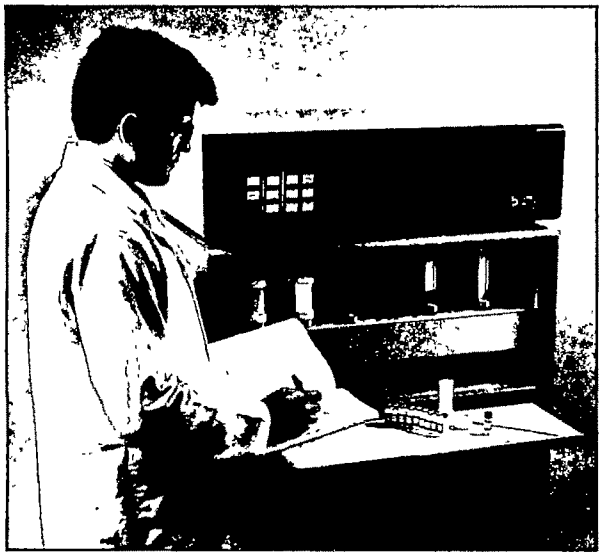
BIOSYSTEMS UPDATE



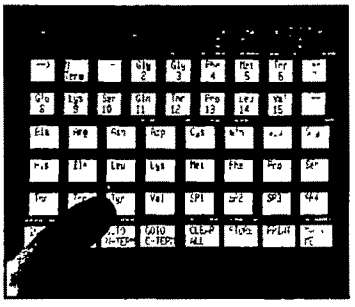
The advanced method for peptide synthesis: Pre-formed Symmetric Anhydrides

Fast, Economical, High Yields

The Model 430A Peptide Synthesizer consistently delivers unprecedented efficiency and economy. It is the first automated instrument-reagent system that optimally forms *t*-Boc amino acid symmetric anhydrides.

Symmetric anhydrides eliminate or suppress random and most non-random coupling failures. In addition, faster, more economical syntheses are achieved because the need to do double couplings for most amino acids is eliminated.

High stepwise yields are routine; complete cycles take less than an hour and typically consume less than 250 mL of reagents.



The Model 430A Peptide Synthesizer delivers consistently higher yields of far purer crude product at a substantially lower cost per cycle than instruments employing conventional methods which are not optimized for each amino acid.

Unique, Optimized Chemistry

Each protected amino acid, sealed in powder form in an individual cartridge, is dissolved and activated automatically just before coupling. All functions of the synthesis cycle are uniquely specified for the various amino acids. The Model 430A is available with three reaction vessels for sequential syntheses of different peptides.

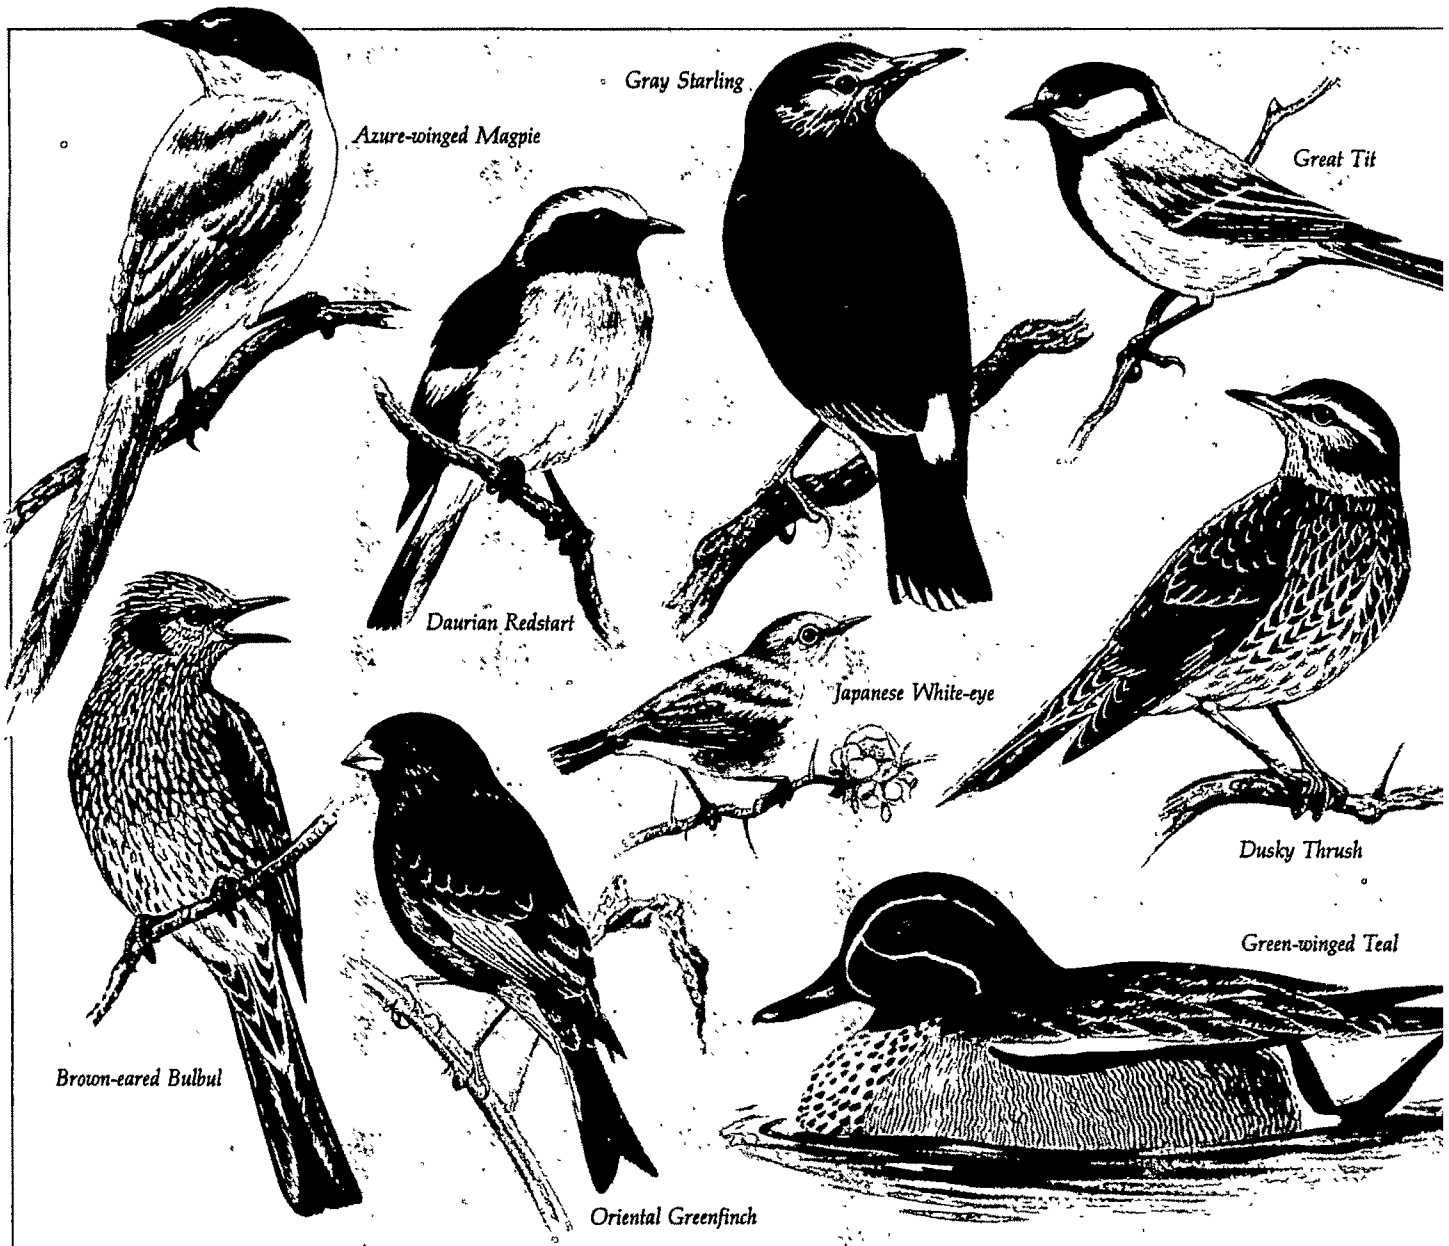
Easy, Touchscreen Control

The Model 430A is simple to operate with its touchscreen control, yet can accommodate multiple methods for the experienced peptide chemist. There is no computer lan-

Peptide Sequence Editor—one of the convenient touchscreen menus that provides the user with complete control, plus the flexibility to modify existing protocols or write new ones to accommodate different pre-activation methods including FMOC.

guage to learn—no complicated control panel or keyboard to master. Pre-programmed algorithms automatically integrate each synthesis cycle for the shortest time, even when new protocols are created.

A Complete Instrument-Reagent System



High purity PAM and BHA resins, and a full line of quality amino acids, reagents and solvents are integral components of the 430A system for consistently superior performance. Complete user support includes the assistance of Applied Biosystems scientists and a worldwide network of trained service engineers.

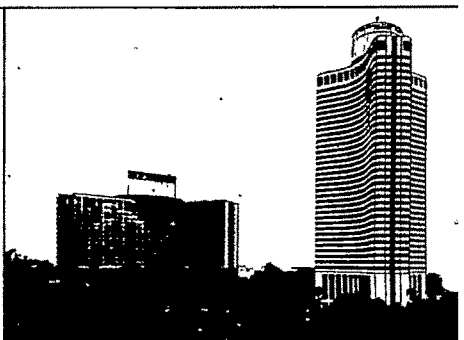
Our Other Guests



Guests just seem to flock to the New Otani Hotel. And to its 10-acre, 400-year-old Japanese garden. A garden so peaceful that it's hard to believe you're in the heart of one of Tokyo's business and entertainment centers. You may even be lucky enough to glimpse a crane — or that rarest of sights, the international businessman with a moment to relax.

Yet the garden is merely one reason the New Otani Hotel has become a Tokyo attraction. Branches of the world's best-known shops and restaurants can be found in our international arcade, while our service is anything but garden variety.

The New Otani Hotel; in Tokyo, it's the natural choice.

For reservations and information on New Otani Hotels in Tokyo, Los Angeles, Honolulu and Singapore, please contact The New Otani International Sales Offices:

Robots and images galore

Japan's massive science and technology fair, Tsukuba '85, opens this week in Tsukuba Science City. It is well worth a visit.

AT the end of the movie showing in Toshiba's pavilion at Japan's Expo '85, a young Japanese boy turns to a white-coated scientist and symbolically hands him a baseball. A robot with expressive eyes who has guided him around a research lab looks on, cooing electronically. The boy has decided to put aside his dreams of becoming a baseball star and become a scientist. The overwhelming message coming from the Japanese pavilions at the international exposition — on the theme "Dwellings and surroundings — science and technology for man at home" — is "Love science and technology".

The message comes in various forms:

"The affluent life of the twenty-first century begins amid the harmony of life and science", whisper the loudspeakers in Mitsubishi's "Wonderful world, beautiful people" pavilion as viewers ride cars on a trip beyond time and space.

"As management systems advance, accuracy and safety will increase, this will allow everyone in the community to enjoy life", says the commentary in Hitachi's rotating Interface Theatre.

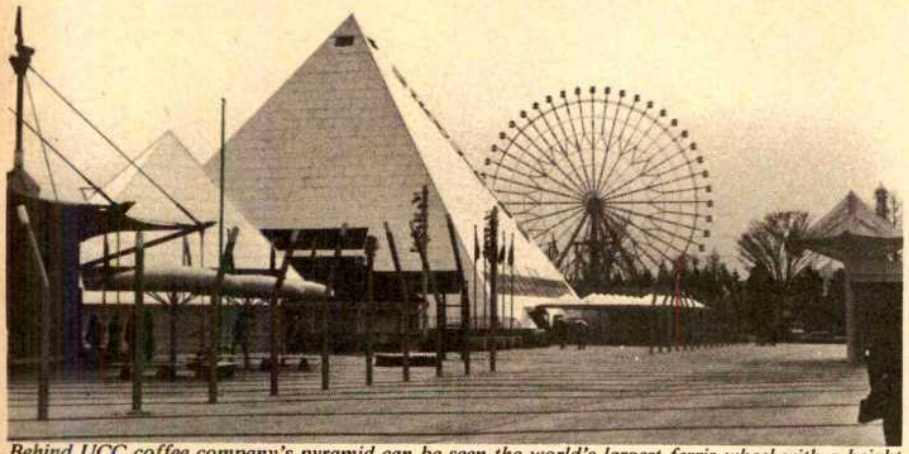
"Technology can be fun", say the slogans in the Fujitsu pavilion.

And the epilogue in the government's history pavilion is "While each part acts independently, the whole functions with a beautiful order; just as the relation between the body and the cell so the relationship between society and scientific technology will grow". Alongside the message a sculpture of waving disks on tall, flexible poles demonstrates overall harmony in independent movement; surrounding video monitors show aerial views of *masu geemu* (mass games) of people on a playground — only when viewed from afar can the overall order in apparently chaotic movement be discerned; ever-changing flower-like patterns emerge. "This is the future harmony between man and technology", explains a guide clad in a silver uniform cut into geometric shapes.

The Japanese faith (officially, at least) in the benefits that technology will bring seems untroubled by the doubts entertained in other nations; indeed, perhaps it is just this naive faith the Expo sells that will produce the miracles it predicts.

At any rate the amount of organization and effort that has gone into the Expo is truly spectacular, as is the resultant 250-acre site covered with futuristic pavilions from the Japanese government, 28 Japanese corporations, 47 foreign countries and 37 international organizations. Spectacular too is the number of people expected to attend. Recent surveys suggest that the original guess of 20 million visitors during the six months of the Expo is on the low side, more like 26 million people are likely to attend — more than one-fifth of the entire Japanese nation. What better way to accustom people to the high-technology future that lies ahead? That is, if all 26 million people can get there — huge traffic jams at the preview suggested that it is not going to be easy.

The Expo has not been cheap to set up. Some 210,000 million yen ($840 million) has been spent, with one-third of it coming from private industry and the rest from the government. The official theme of the Expo, on "Dwellings and surroundings", seems not to have been taken that seriously. At the very beginning, it had been intended to hold an Expo simply on the theme of science and technology, but it had been pointed out (by the controlling body for international expositions in Paris) that this would virtually bar all but the advanced nations from participation. Thus the adoption of a more specific theme; it was thought (by a somewhat dubious bit of logic) that the less advanced nations could display technology appropriate to their particular "dwellings and surroundings" and the emphasis on high technology lessened. Indeed, that and very generous financial terms offered to the developing countries by the Expo organizers has ensured greater Third World participation than at any previous Expo. But for the Japanese contributors to the Expo — the two government pavilions and the 28 corporate pavilions that dominate the Expo and take up around 70 per cent of its space — it is still fundamentally an exposition of science and technology pure and simple. A walk around two-thirds of the pavilions revealed a model of only one dwelling (a solar house), no contribution from construction companies, and rather little in the way of new items for the home; the emphasis is rather on the boundless (and often rather abstract) advantages of high technology presented with all the razzmatazz of a fairground.



In building the pavilions, and the corporations have lashed out around 2,000 million yen ($8 million) on each of their own, Japan's top architects have been put to work. Or rather the top well-established architects have. Despite looking to the future, Japan's young architects have not had a look in; it is Kurokawa Kisho (who designed the Japan exhibition held at the Royal Academy in London a couple of years ago) and Maki Fumihiko who lead the pack. The result has been a plethora of pythagorean solids: cones, spheres and pyramids galore dot the site. The IBM (Japan) building manages cleverly to combine a cone, a sphere and a square; the Toshiba building's ground plan is of a square, semicircle and triangle. Clearly the days when geodesic domes were inextricably linked to visions of the future are over; the only big domes are the two of the Midori-kan's biotechnology pavilion, linked together to represent cell-fusion technology. That is not to say that curves have been entirely rejected; the government Expo Plaza building looks like a giant white butterfly come to rest — a pair of outstretched scalloped wings roof an open space for the performance of festival shows. The US pavilion, by Maki, evokes a graceful series of billowing sails and the Electric Power pavilion consists of dozens of white tent-like structures with sharply-pointed peaks pulled out by wires running to the top of a tall, slim tower.

The Tsukuba Expo abounds in the world's biggest smallest and fastest. This is the Sony Jumbotron, the world's largest television. Some 25 metres high and 40 metres wide, beside projecting futuristic images it will be used for a world news service.

Tsukuba Expo '85

THIS feature is by *Nature*'s Tokyo Correspondent, Alun Anderson, except where indicated. Japanese names are written with the surname first. The International Exposition, Tsukuba, is to run from 17 March to 16 September. The Expo site can be reached from central Tokyo in 2 hours.

Behind UCC coffee company's pyramid can be seen the world's largest ferris wheel with a height of 85 metres. Each gondola can carry eight people. There are worries that it may be struck by lightning, as the plain surrounding Tsukuba is notorious for mid-summer thunderstorms. The organizers assure doubters that it is absolutely safe and that the odd thunderbolt will only add to the excitement.

Traditional Japanese touches are provided too, again by Kurokawa. A long line of simple buildings with walls of cream ceramic squares set in black steel frames recall the sliding screens of traditional Japanese houses. A few pavilions have aimed at the downright exotic: Shueisha has a massive mock stone building covered in primitive carvings and exhibits a mummy from the British Museum for its theme of "Historical proof of Man"; and Daei's "The home of the poet" building is a low, stepped pyramid with its entrance hall underground.

Like expositions elsewhere, almost everything on the site is to be torn down when it is over (the area will become an industrial park), so the building of fantastic and ephemeral forms has been encouraged. It is impossible not to be impressed by a walk around the site, not only by the originality of the buildings themselves but by the sense of space with which they have been laid out.

Strangely, although the government has repeatedly said the whole exposition will present a "vision of the future", in actual fact no coherent picture of what future life may be like emerges. There are some individual exhibits — like that of NTT's Information Network System — that deal with bits and pieces of the future. But mostly on display are images — on giant screens, in 3-D, on high-definition televisions — and robots.

In the Fuyo robot theatre there are fifty self-propelled robots of twenty different kinds (but mostly of a very cute kind that only children will be able to tolerate), a talking robot roams the main open space (and switched into English while talking to this correspondent and followed him shouting "I want to go to England"), a robot plays the organ and reads music in the theme pavilion, Matsushita's robot draws portraits after a ten-second look at a face, Hitachi's assembly robots get out of the factory and spend their time sculpting ice blocks, Toshiba's robots spin traditional tops and can send them along tightropes to one another, Fujitsu has the world's largest humanoid robot. More than science and technology itself, maybe it is robots that you must learn to love!

But why, in Japan of all places, has it been found necessary to go to all this trouble to inculcate a love of science and technology in the citizenry? Clearly, both industry and government have already decided that Japan's chief hope for continuing rapid growth and prosperity lies with high technology — innumerable government reports and exhortations have already driven the point home and the key products for the new era are on display at the Expo — intelligent robots equipped with sensors, electronic imaging equipment, machine translation systems, high-definition television.

But strangely, when seen against Japan's volume of high-technology exports, the people of Japan have perhaps had less contact with the new technology than elsewhere, and science and technology are still very much seen as the domains of "experts". Take some of Tokyo's most highly automated big offices for example; they may boast that they lead the "OA" revolution in Japan but the fact is that workers spend rather little time at electronic keyboards and rather a lot of time in old-fashioned face-to-face group discussions. Often companies are not themselves using on a large scale the technology they are selling abroad. Again, small computers are very much more widely diffused in schools and homes in the United Kingdom than they are in Japan. An exhibit in the British pavilion claims that "Young girls and boys in Britain are now learning the language of new technology as naturally as their mother tongue"; given the number of small computers available in Britain it may well be true. The same could not be said of Japan, even though Britain's computers are doubtless full of Japanese microchips.

Also the pace of Japan's industrialization has left some groups out of touch. The rapid post-war shift of population to the cities has left behind a population in the countryside with a very different level of contact with high-tech; older people, too, feel more threatened by technology and will have had a much clearer experience of its ill-effects. Those who lived through the 1950s and 1960s, when nothing was allowed to stand in the way of high growth, will have clearer memories of Japan as the pollution capital of the world: Minimata disease, photochemical smog, arsenic accidentally introduced into milk, Itai-Itai disease....

In one sense, then, the Expo aims to strengthen a national consensus that the only way to move ahead is with high technology, to prove that science is not something "dry and stiff" but is something to enable people "to live in happiness". The Expo too is a festival celebrating just how much Japan has achieved already and how much technology is now part of daily life.

Apart from a little revision of history in one government pavilion, there is no evidence of nationalism or of a desire to boast of Japan's very remarkable achievements. But Japanese visitors to the Expo must feel an immense sense of pride in the wonders that are on display there. Perhaps it will bolster their sense of optimism for the future too.

The Expo also serves several subsidiary purposes, the principal one being to put Tsukuba Science City, on the fringe of which Expo stands, on the map. For all its

Nature's Tokyo correspondent as seen by Fuyo's robot.

46 laboratories and institutes, its two universities and its 34,000 scientists, and the million million yen that has been spent on it, it still has not captured the imagination of Japan's citizens (see *Nature* **305**, 378; 1983). Perhaps the Expo will make it seem a brighter, more exciting place and help attract the population it is still lacking.

The style in which propaganda for the twenty-first century has been put over is very typically Japanese, even though the Japanese themselves may not be aware of

it. Two separate but entwined influences can be seen at work. First, there are the two trends in Japanese art (and life): towards extreme understatement, the ultra-refined, and the use of absence and emptiness to suggest presence; and towards the noisy, the colourful, the boisterous and the vulgar.

The first world is that of traditional Japanese gardens where a few rocks and some carefully raked gravel suggest a universe, of the exact placing of a few flowers in *ikebana* (flower arrangement), of the slow and subtle gestures of the masked actor in a Noh play, and of careful understatement in speech. This side of Japanese aesthetics is the better known in the West. But the other extreme also exists of wild and drunken festivals, of colourful Kabuki plays, and of grotesque and garish Edo-era paintings of actors and prostitutes and demons. In origin, the two cultures belong respectively to the samurai that ruled Japan throughout its feudal period, and to the common people, particularly those of Osak and Edo — what is now downtown Tokyo.

Much of Japan's commercial television seems to spring from the latter source: there always seem to be two or three people shouting at once, lights are flashing, and girls are shrieking in an endless party from which everyone with a trace of introversion has been excluded. But a walk around Tokyo reveals that the opposite trend has by no means left Japan's everyday culture. Take a famous fashion chain store: passing by one of their shops a foreigner could be forgiven for thinking it had gone out of business. All that can be seen is a large marble slab with a single black garment on it, the racks of clothes for sale are kept out of sight so that they may not intrude on the elegance of the bare interior.

Or take the following television commercial. A view of a wall full of windows fills the screen; as the camera pulls gradually back it is revealed to be the side of a tall American skyscraper; a single long strip of paper falls from the sky, twisting and turning as it drifts down through the centre of the screen — and is then replaced by the name of a brand of mayonnaise, without any apparent connection to the images that have gone before.

What this commercial illustrates is not just a partiality for minimalism, but a second trend also seen at work in the Expo, perhaps best caricatured as a "disinterest in facts". However many commercials you see on Japanese television, you would be hard put to find one that gives you any facts about the product — or even a good reason why you should buy it. As an advertising agent who boosted Sony's Walkman to success put it, "we stress the emotional benefits of the product, not the physical properties". Everything aims at the evocation of an ambience, a mood to be associated with the product — not at conveying information about the product. Indeed, Western society is often described as too oriented to facts, what the Japanese call "dry". Instead, they are (or like to think of themselves as) "wet", as being primarily concerned with their emotional reaction to things.

At individual Japanese pavilions in the Expo, the tendency towards extremes of understatement and over-statement can be clearly seen. So too can the tendency to rely on emotion rather than logic. For Westerners the chief criticism of the Expo would be that it dazzled rather than informed. One suspects that many Japanese would not really care. A Japanese corporate participant apparently shrugged off comment of this kind with "However educational and profound the theme may be, it's a waste of time and money if no visitors come". So the emphasis is on spectacle, fun for all the family, and slogans. There is another important consideration; the crowds are expected to be so huge that if anyone stops to press a button or think too long it might bring the whole Expo to a halt!

Nevertheless, there are many thought-provoking exhibits at the Expo and some of the best (for this reviewer) are described in the pages that follow. Pavilions of foreign countries, too, present their own individual styles — many of them the "high information" style that is more common in the West. It will be interesting to see how the Japanese react to them, and how the million or so foreign visitors expected to come react to Japanese exhibits. All in all, worth coming a long way to see. □

Japan Airlines' experimental High-Speed Surface Transport, on view at Expo, uses magnetic levitation for lift and a linear induction motor for propulsion at up to 300 kilometres per hour.

The theme: science cool and wondrous

THE spirit of refined taste is one facet of Japanese culture that is seen at its best in the government's Theme pavilion. There is no clutter, nothing obtrudes and there is often a remarkable sense of peace; even the couple of monitors showing videofilms do not sit clumsily by displays, they recline in elegant glass cases as though exhibition pieces in their own right.

The first hall, Sun and Water, is high, light and airy and contains what has become through intensive media exposure the star of the Expo: a giant tomato plant. Grown from just one seed, the plant will demonstrate the potential of hydroponic farming techniques; if all goes well it will reach ten metres in height and produce 12,000 tomatoes by the end of the Expo. So far it is growing on schedule, and managed 30 tomatoes for the press preview two weeks before opening day.

The second hall, Man, is more surreal. In semi-darkness on a central octagonal platform, a silver, metal man-like robot plays the organ (a little soullessly) from sheet music read by a single television eye set in the centre of its head. To one side, wall panels show an ever-changing pattern of nude human bodies — the female conveying "grace, beauty and warmth" and the male "strength and vitality"; to the other side a quadruped robot looking like a gigantic black ant crawls slowly up a staircase, a frill of sensors around its feet feeling for the next step; behind paces a strangely truncated bipedal robot — just a pair of walking legs ending in a squat metal box.

The last hall, Outer Space, is dark and cathedral; images are projected onto a screen from an Earth satellite while a golden model of it rotates silently alongside. On a moving walkway, one sails slowly across a vast elongated screen filled with images of molecular structures, planets, suns and nebulae that turn into the radial arms of colossal space stations. The journey ends in a corridor of sloping mirrors and bright red fine scaffolding that gives one the impression of having landed inside an infinite cubic lattice.

Along the way there are quite a few objects: the Shinkai 2000 deep-sea vessel hangs in the "Sun and Water" hall, and the silver multiple compound eyes of the solar ray concentration and transmission system stand at its centre. An NMR scanner, a laser scalpel and an organic holography display stand quietly in the "Man" hall. The second stage of the HI rocket has a corner in the "Space" hall. A separate open area — a future town plaza — in elegant greys has a model solar house and a city of the future.

But the real emphasis is not so much on things or on how they work, or on presenting a glimpse of the future; it is more to create an almost religious state of awe. Whatever science and technology is, it is something strange and wondrous. □

History pavilion

A little judicious rewriting

GIVEN the overall aim of the Expo to create a new feeling of warmth towards science and technology in the hearts of Japanese citizens, it is not surprising that the view of the past should require a little revision. In the process, some old and misleading myths about Japan have been thrown out.

What the first half of the government's "History" pavilion does is to chart factors responsible for the first Japanese miracle: the very rapid modernization of the country after it opened its doors to the West and abolished the Shogunate in 1868. Indeed, progress was so fast that within the space of a few decades Japan went from an isolated feudal country to a major power that was capable of defeating the might of the Imperial Russian army and navy.

Understanding of this leap forward is particularly important for developing countries, especially those in South-East Asia, who frequently try to take Japan as a model for their own development. The exhibition makes it clear that success did not spring from unprepared ground and was not due to some inexplicable spirit of the Japanese. First and foremost, even before direct contact with the West, Japan had a population that was highly educated and literate. Information panels (unfortunately written only in Japanese and thus inaccessible to foreign visitors) show how there was a major boom in small *terakoya* schools which gave basic education in reading, writing and the abacus in the early nineteenth century; by the middle of the same century it was almost certainly true (as it still is) that the Japanese were the most highly educated people on Earth.

It was to this relatively enlightened population that the best of Western technology was brought in to be imitated and improved upon. A series of intelligent decisions were then made to allow technology to disseminate quickly; some of the very first university engineering departments in the world were opened, systematic methods of measurement were introduced, a patenting system set up, and industrial standardization was adopted early on.

The defeat in the Second World War destroyed the material fruits of this effort — then came the second economic miracle and Japan's current technological successes. Explanations for these are much more abstract and fall back into clichéd explanations about the "special characteristics" of the Japanese people.

Beautifully arranged exhibits of traditional laquerware alongside the Sony Walkman show the Japanese sensitivity for "lightness"; a stylized Zen garden illustrates the Japanese desire to "control time and space"; a *karakuri* doll — a kind of sophisticated mechanical doll worked by levers which was first produced in the seventeenth century — is shown with a caption which links past interest in these dolls to the modern achievements in robotics (the "robot spirit"?). Japan is one of the few countries to endlessly dissect its "national spirit" to define its unique characteristics — the doll exhibit is as silly as one would be that put Victorian English miniatures alongside microchips (the technology was invented in the West, not Japan) to prove a British "love of the small".

Curious too is an exhibition of traditional technologies. A staggering set of six multiple projection screens with an overpowering sound system dominates a great dimly-lit hall at the back of which giant water wheels slowly turn. On the screen, flashing images of traditional sword-making, and from the loudspeakers a mighty cry as the red-hot sword is plunged into clear water. The message is a very fair one; that in the past Japan had independently developed sophisticated technologies. But the exhibit captions go beyond this and seem to suggest that there is a native Japanese science and technology, a scientific tradition that is uniquely its own; as though there were a difference between "science" and "Japanese science". Lying behind this there is perhaps some feeling that "science" is still in some sense an import and that proving there is a Japanese science will somehow make it more acceptable or lovable.

Having set out to destroy some myths about one miracle, it is a pity to see the exhibition introducing new myths along these lines. How much better the IBM (Japan) pavilion's attitude to history; Japanese scientists, as fine as any other nation's, take their equal place alongside foreigners in one international science. □

A touch of class from the British

LACONIC understatement, either a virtue or a character trait, marks the British pavilion. The designers have set out to ensure that visitors will not be impeded in their hunt for another stamp on their Expo passports by buttons crying out to be pressed. Instead, there is a cunning array of video screens hidden in structures as different as breaking waves and seashore rocks. Backward-looking (or historical) information has been avoided as if the plague. And to avoid carrying coals to Newcastle, the planners have made much less of the British government's domestic ambitions for information technology than might have been expected. But Sir Clive Sinclair has been persuaded (apparently reluctantly) to put the latest version of his Spectrum computer on display, while the UK programme for encouraging the use of computers in schools is heartily endorsed.

The first objective of the exhibit seems to be to let people know what Britain looks like, both to the eyes of visitors (accomplished by means of life-size cut-out models as in those of pop-up children's books) and by Landsat images collected from Earth orbit. If necessary, the exhibit will also demonstrate to visitors exactly where Britain is, apparently a matter on which many Japanese are uncertain.

Environmental protection, typified by the return of salmon to the Thames, looms large, as do some of the recent developments in medicine (NMR scanning, for example) and pharmaceutical research (H_2 antagonists for treating gastric ulcers, for example). The IRAS satellite is represented by a model that could well have been larger, but the infrared image of the Milky Way is as arresting as anybody could wish.

On balance, the impact of this modest display on visitors is likely to be pleasing and reassuring. Even before the video displays had been switched on, and the lights darkened, the sense of unpretentious orderliness was clearly apparent. Some may think that the decision not to look backwards notwithstanding, more might have been made of British contributions in basic research — in molecular biology, for example. But what, in any case, will stick in people's minds is the largest single object on show, a sleek Jaguar coupe in royal blue. Apparently the taste for these machines is catching on even in Japan, with the result that one is to be seen most days on the neighbouring parking-lot, the property of the manager of a nearby pavilion.

John Maddox

Pacific rivals

AUSTRALIA and Korea inhabit spacious pavilions, as befits fellow-Pacific states. But there the similarity ends. Australia plainly wants Japan to know where it came from. Korea's message seems to be that Japan should watch out for a rival to the West, and in the meantime spend its vacations in Korea.

Australia's history comes across in sepia-tinted blow-ups, with as full an account as anybody could ask for of the precedence accorded to the aboriginal population. Heroic eighteenth and nineteenth century settlers create a melting-pot to which Asian populations have since been added. Now there is a modest boast about Australia in astronomy, and about the keel that won the America's Cup from the United States. A dashing video display says perhaps only half of what might be said about the splendour of Australia as a place. Korea, by contrast, makes itself seem a little like Japan but more exotic (which is fair). Its high-tech products are relatively modest — cars, telecommunications equipment and so on. But the similarity is in itself enough to suggest the threat of competition from around the corner.

Demonstration Plant for Continuous Alcohol Production. (10kℓ×2)

Kyowa Hakko, Japan's biotechnology leader, has begun fresh research in recombinant DNA, large-scale plant/animal cell cultivation, cell fusion, bioreactors and more. This follows our success in interferon β and γ production by recombinant *E.coli* plasmid, and more recently, our mass production of salmon growth hormone. We have also developed a host-vector system using Coryneform bacteria through creative research that opens the way to improved amino acid productivity.

Kyowa Hakko is now pioneering the commercial applications of these technologies. For example, we have already achieved over 4,000 hours of continuous alcohol fermentation with living immobilized yeast. Ten kiloliter demonstration plants are currently in operation. Productivity is more than 20 times that of conventional batch-wise fermentation.

KYOWA HAKKO is changing the world of biotechnology.

Corporate pavilions

Electronic extravaganza

GOING over the top to prove that technology can be a barrel of fun are the big Japanese electronics corporations — Toshiba, Sumitomo, Matsushita, Hitachi, Mitsubishi, Mitsui and the Electric Power corporations. And for children and their mums and dads on a day trip to the Expo the whole experience probably will be great fun and a lot closer to a day at Disneyland than at a science museum.

The first three corporations offer films as their main attraction, the last three rides — a kind of high-tech ghost train — and Hitachi in the middle combined the two with a rotating movie theatre. Among the rides the "Electrogulliver" trip offered by the Electric Power corporations is by far the most unnerving.

The ride begins with thirty seconds of complete and total darkness, after which the chair makes a sudden lurching descent and its occupant is hit by a fine spray of cold water. This turns out to be preparation for a quick steam in a very hot volcanic magma chamber. After that the traveller goes through a forest inhabited by twitching purple cockroaches and into the heart of the Sun to participate in a nuclear fusion reaction — an environment available in 3-D and computer simulation in pavilions elsewhere, so the visitor to Tsukuba soon becomes perfectly at ease with a few protons flying excitedly about.

Elsewhere there are rides into space and past black holes, and in Mitsui's water theatre the adventures of a boy and robot, incorporating a film projected onto a giant circular waterfall surrounding the ride.

Indeed, exhibitors opting for film are nowhere content with mere conventional projection systems. 3-D is everywhere. Sumitomo boasts Japan's first purpose-built giant 3-D screen and a moving tale of a little girl and her sheepdog "Bozo", and Hitachi the world's first 3-D colour computer graphics and a curiously old-fashioned view of the future, with robots vacuum-cleaning and scolding children for not doing their homework in a story much like that of comic strips of 20 years ago. Toshiba has a super-reality theatre using film taken and projected at three times the normal speed for the ultimate image. Special effects are provided by the maker of those for "2001" and "Close Encounters of the Third Kind" and contain the best robot ("Pal") in the Expo.

Some pavilions also have some technology on display. Toshiba's robots are particularly impressive. One inspection robot and five one-armed assembly robots deftly spin traditional Japanese tops and make them walk a tightrope. Alongside is state-of-the-art medical imaging equipment — magnetic resonance, tomographical X-ray and ultra-sound — and an astonishing pattern recognition machine that can sort out foreign banknotes at the rate of 1,500 a minute. To make the machine more lovable for the Expo, it does not actually touch any money but sorts out five kinds of cards depicting scenes from fairy tales. Unfortunately the machine still looks for all the world like a giant metal-and-glass sarcophagus — a few pink ribbons might have improved it.

Most pavilions rely simply on spectacle. You certainly will not learn any science from them (or see much real technology) and Westerners are in danger of emerging with a fuse blown somewhere. But Japanese children have been reared on their local television and are made of sterner stuff. They will be queuing up for more until the Expo ends. □

Film projection onto falling water is Mitsui's main attraction.

Four million pairs of 3-D glasses will be given away during the Expo.

NEC pavilion

A place for galactic heroes

FUN and games with the future, the insistent theme of the Japanese pavilions, will be eagerly sampled at the Nippon Electric Company (NEC) pavilion, most easily recognized by the 32-metre parabolic antenna which towers above it. There was some embarrassment, on the day it snowed heavily at Tsukuba the week before opening day, that workmen had to keep the crowds away from the lumps of slush falling from the rim until the dish could be pointed to the zenith.

NEC has built a theatre for playing interactive computer games. Visitors are given a piece of plastic, not called a credit card but called a boarding pass, that will activate a small computer terminal in front of every seat. A film whose script begins with Neil Armstrong's observation on landing on the Moon puts the audience into a space ship whose navigators repeatedly run into swarms of meteorites and, now and again, a black hole. At the approach of each potential catastrophe, everybody's seat vibrates. Those who make the wrong choices of a strategy for escaping find that their seats tilt back alarmingly. Half-way through the show, there is an exercise at destroying meteorites with a ray-gun, when each terminal records its user's score.

Crude though it may be, this jazzy show cannot but be a hit. NEC has probably underestimated the queues there will be, with merely 30 square metres set aside outside for standing in line. But those who will be waiting under cover will be treated to a 5-minute quarrel between three television sets whose screens are not merely filled with cleverly drawn animated faces, but which can nod and shake so tellingly that even those who cannot understand the Japanese will think them alive.

NEC's motto for the present is "C & C", which means computers and communications. The company has set out to simulate something of what it thinks the next century will be like in what it calls its Techno-Plaza. There is a vehicle with a computerized guidance system that locates it on a moving map display, and which tells the driver when and which way to turn at intersections. Just as well, visitors will conclude, for the driver will otherwise be too busy using the tricks with which the vehicle is equipped for sending documents back to head office and retrieving data from the databanks. NEC apparently has no immediate plans to put its car on the market.

Two of the exhibits are more telling: a group of three six-jointed robots, or simulations of human arms, which are wired and programmed in concert to carry out co-operative tasks, and the prototype of a telephone interpreter that will convert spoken Japanese into spoken English. NEC has for some time been putting a large part of its research and development into artificial intelligence. If the rough edges of its interpreting telephone can be smoothed out, it may not have to wait until 2000 to have something to sell.

John Maddox

Fujitsu pavilion

Toughest robot in town

What mankind can dream, technology can achieve ... Robots act for us, machine translation systems think for us ... computer imaging technology simulates realities beyond our realm of perception.

ALTHOUGH Fujitsu falls in with most other corporations in its glorification of technology, it does so with a little more style; some interesting exhibits are on display and its 3-D film is streets ahead of anyone else's.

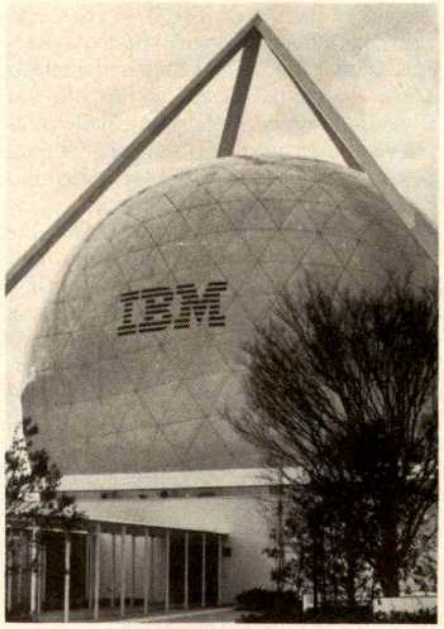
Dominating the exhibition is the world's largest humanoid robot, Fanuc Man; 5 metres tall, weighing 25 tons, and kept in a special cage which makes it look as though it is eager to break out and start climbing skyscrapers. But Fanuc Man is,

symbolically, both gentle and strong. For the amusement of visitors it alternates between the dexterous task of assembling a one-thirtieth scale model of itself, aided by television cameras set into its hands, and pressing a 200-kg barbell (not by sheer brute force but by careful load balancing). Fanuc Man and his like are destined to assist one-armed robots who spray paint and spot-weld cars with the assembly of heavy components — doors, seats and so on.

Japan's lead in robot production is pretty much unquestioned. But software has been considered a different story, with Japanese thought lagging behind their US and European counterparts in creative ability. Fujitsu makes that point but claims that the software used at the Expo shows just how quickly things are changing. Fujitsu believes its machine translation system to be the world's most advanced and it is set to work at the Expo translating Japanese sentences — written by children at a booth on their way into the pavilion — into English, French and German for projection on a screen elswhere in the building. A Fujitsu engineer was happy to admit, though, that even a short sentence takes 15 minutes of mainframe computer time to translate. Just why is not hard to see. Japanese is written without breaks between words and the first step must be to segment the sentence into words through a dictionary and information about the adjacency relationships of words; only then can a context-free grammar be put into use to parse the sentence and identify grammatical elements. Next comes the really difficult bit: the computer has to have some sort of commonsense world model to figure out which particular meaning of each word is intended — it has to "understand" the sentence — before a translation can be attempted. Fujitsu uses the semantic network approach; essentially a hierarchical grouping of words with linked meanings (a bit like the organization of a thesaurus rather than a dictionary), as a part of a knowledge base. It is after this stage that words from a different language with corresponding meaning can be selected.

Clearly the problems are very complex and general purpose machine translation with enough knowledge to handle the rambling sentences written by real people is a long way off. But in restricted fields where ambiguity has been deliberately eliminated, progress is expected to be more rapid. Within five years, Fujitsu expects computers to handle almost all translation of technical manuals; technical translators may be the first highly skilled white-collar workers to be made redundant by computers.

The other software advance of which Fujitsu is keen to boast is that used in generating the company's new 3-D film — the world's first 3-D computer graphics film for projection on a dome. The film depicts a journey inside ice crystals, through the planets, and into the Sun to see the mechanism of nuclear fusion, and ends with a sensational simulation of a DNA molecule being wound and rewound and re-



packed until it forms a chromosome. Days of computing time on one of the world's largest and fastest supercomputers were needed to generate this sequence; the intention was not to produce a cartoon but to produce exact simulations based on the most recent molecular models. Many a 3-D film at the Expo promises a trip inside a "different dimension" — Fujitsu's is the only one to achieve it. □

IBM (Japan) pavilion

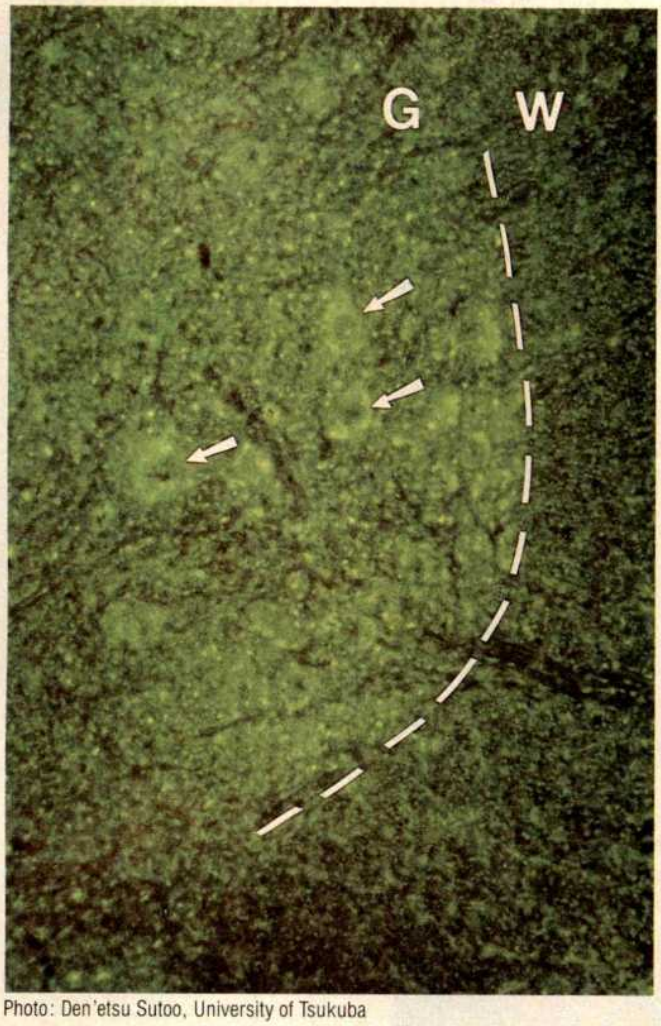
A touch of wisdom

AMONG the domestic pavilions, IBM (Japan) would have to take the prizes for exhibits that are both fun and teach one something about science. Responsible for the overall organization was Nobel-prize winner Leona Esaki, who now works for IBM, and a team of top Japanese scientists—the difference shows. What IBM wanted to get over was something of the spirit of scientific discovery and of the way each scientist builds on what has gone before. The latter is attempted through a picture and text wall display of key periods and individuals in the history of science. The earlier periods — the Ancient Greeks beginning with Pythagoras, passing through the contribution of men like Avicenna from the Arab world to the Middle Ages and the revolution brought about by Brahe, Kepler, Galileo and Newton — were pretty much what might be expected. From then on a newer view of the history of science emerges.

First, there is the transition in the early eighteenth century when "the religious motivation to demonstrate God's will through the understanding of Nature's laws gradually gave way to the study of Nature for its own sake, or... for material benefits" — the age of Watt, Franklin and Cavendish. Then follows the Age of Specialization, that of Darwin, Maxwell and Edison, when scientists founded professional societies and "sought recognition through short papers on specific topics rather than lengthy treatises attempting to explain all natural phenomena as elements

The IBM pavilion takes its form from paintings of the nineteenth-century Zen priest Sengai — the circle, triangle and square respectively symbolize the Universe, human intellect and Earth.

Instruments of a New Age of Exploration



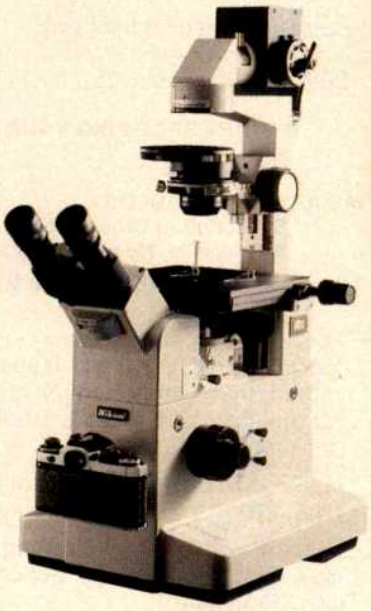


Photo: Den'etsu Sutoo, University of Tsukuba

The ongoing challenge of nerve research—potentially one of the most rewarding research endeavors in advanced biochemistry. Nikon brings you this brief glimpse of how man and machines are working together to deliver new views of the nerve world.

The project: Exploration of the central nervous system. More specifically, investigation of the synthesizing mechanism of acetylcholine and catecholamine and the function of their neurotransmitters.
The significance: Greater understanding of the emotions and behavior of humans and animals; further elucidation of epilepsy, alcoholism, neuroblastoma, etc.
The process: As shown in the photograph, the ventral side of a mouse cervical spinal cord was immunohistochemically stained for choline acetyltransferase. Grey matter, white matter and motoneurones are represented by G, W, and the arrows, respectively.
The equipment: Nikon biological microscopes and Nikon's Microflex photomicrography system. The advanced photometer of the system was crucial in determining the amount of a particular neurotransmitter or its related enzymes present in smaller nerve regions.
Nikon microscopes have been aiding scientific progress for over 60 years. Whatever your microscopy/photomicroscopy needs may be, Nikon has the system that's perfect for you.

Circle No.12 on Reader Service Card.

CONVENIENT·INFORMATIVE·TIMELY·PROVOCATIVE

FOUR DYNAMITE REASONS WHY YOU SHOULD SUBSCRIBE TO BIO/TECHNOLOGY NOW . . .

1 ■ You'll save time. Because you don't have time to read every journal in the field, BIO/TECHNOLOGY is written and edited to give you all the information you need in ONE convenient source. BIO/TECHNOLOGY is the only journal to give you news. Features. Original research. Product evaluations. Industrial applications. Job openings. Book and product reviews. And more. If it's important to your work, you'll find it between the covers of BIO/TECHNOLOGY.

2 ■ You'll learn new ways to improve your on-the-job skills and run a more successful operation. Each month BIO/TECHNOLOGY gives you the scoop on invaluable start-up information . . . the latest instrumentation . . . marketing breakthroughs . . . funding sources . . . new technologies . . . patents and licences . . . profiles on how others are avoiding the pitfalls and reaping the rewards. In fact, just one practical tip from BIO/TECHNOLOGY can be worth many times the cost of your subscription.

3 ■ You'll be up-to-date on all major industry developments. With correspondents all over the world, BIO/TECHNOLOGY delivers the inside story on who's doing what, where. You'll get the latest word on changing government regulations and tax law, and how they affect your work.

Plus you'll read original research papers by bench scientists, engineers, and biologists that will help keep you in the forefront of every new discovery worth knowing about.

4 ■ You'll get new ideas you can put to use immediately. BIO/TECHNOLOGY lets you rub elbows with eminent scientists, tour new facilities and learn how new processes work in every field from genetic engineering to molecular biology. Each month, BIO/TECHNOLOGY helps spark ideas for your own research, for new industrial applications and for getting along in the increasingly competitive financial arena.

If you're not already subscribing to BIO/TECHNOLOGY, don't delay the moment any longer - return the coupon below and we will send you twelve issues. You risk nothing. If for any reason BIO/TECHNOLOGY doesn't live up to your highest expectations, just let us know and you'll receive a full refund on all unmailed copies. Remember too, that your subscription may be tax deductible.

TO START RECEIVING YOUR SUBSCRIPTION, FILL OUT THE COUPON BELOW AND RETURN WITH PAYMENT TO:

U.S.A.: BIO/TECHNOLOGY
Subscription Order Dept., P.O. Box 316
Martinsville, New Jersey 08836 U.S.A.

To speed up your subscription in the U.S.A., call toll free 1-800-524-0328.

of a single system". This was the period when *Nature* (the journal) was born — not that all its papers were that short.

In our own century came the Age of Technology, when immediate industrial applications came to be expected for research results and "military research in particular flourished" — a remark that would be commonplace if it were not the only reference to the military uses of science spotted in the whole Expo. And now we are in the Age of Big Science.

Along the way, Japanese scientists who had made a contribution to the world's science are introduced quite naturally, in contrast to the government's History Pavilion, which attempts to establish that there is a "Japanese science". The four Japanese Nobel-prize winners, Yukawa, Tomonaga, Fukui and Esaki himself, are of course mentioned but so are others who are not well known in the West but should be: among them Shizuki Tadao (1760-1806) who introduced newtonian mechanics to Japan, Kitasato Shibasaburo (1853-1931) who discovered the plague bacillus, and Nagaoka Hantaro (1865-1930) who created a Saturn-like model of the atom.

To teach you something of what science is about there is a whole series of interactive displays of the type familiar in Western museums, with plenty of buttons to press. In a model of the atom, for example, it is possible to excite an electron into higher orbitals and see it emit a flash of light as it later drops back; on a giant globe one can manoeuvre continents around to follow different stages of the Earth's evolution. Scientific games are also available in plenty — played on a whole roomful of IBM personal computers.

The supposed highlight of the exhibition is a theatre in which 11 synchronized projectors show a film simultaneously on a domed roof and a giant sphere set in the middle of the hall, while spectators are carried around in a circular walkway. The film is designed to teach the relationships and dependencies that exist between man and science and not "simply to dazzle the visitor". All very proper and almost a rebuke to some pavilions nearby. □

NTT pavilion

Electronic future on display

JAPAN'S soon-to-be-privatized telecommunications monopoly, NTT, has seized the opportunity provided by the Expo to try and show that "INS will make life more exciting".

INS (Information Network System) is what NTT believes will be the telecommunications system of the future: optic fibre cable and complete digitization of the transmission systems will usher in the electronic age of videophones, home shopping and banking, instant access to databanks and electronic mail. A model system is already on trial in the Mitaka suburb of Tokyo (see *Nature* **311**, 289; 1984); the very newest gadgets were on display at the Expo.

One instrument not seen before is the scopephone; a telephone with a couple of centimetre-square black-and-white video screens in its plinth and a miniature camera, revealed only by a small opening, under that. The scopephone does not need the high-bandwidth cable that handicaps ordinary videophones or videoconferencing facilities; of course, the picture is not of such high quality, and if the subject moves about too much the picture temporarily blurs before settling down again. But the scopephone gives a perfectly adequate sense of seeing the person you are talking to — and it is cheap. Chances are this could be commercialized on a large scale very soon.

Also new is a miniature fax (facsimile transmitter) built into a public telephone that achieves the transmission of whatever is written on a small piece of paper just the size of a visiting card; it will make it possible for the Japanese to extend their habit of introducing themselves by exchanging namecards even to a telephone call. As most Japanese bow even when speaking on the telephone (the habit is easy to acquire and hard to break) this invention will make the ritual introduction complete — clearly someone in NTT's marketing division had a brainwave.

On display too is a videoconference room, the sketchphone (that enables one to transmit doodles as one speaks) and the CAPTAIN teledata system. But the big problem with all the hardware is a familiar one — what can it be used for? NTT tackled this question by asking what would have happened if the hardware had been available a hundred years ago: a series of sketches performed by actors in small studios around the pavilion gives the result.

One performance comes right out of one of the most curious episodes in Japanese history soon after the Meiji restoration had opened Japan to the West. The setting is the Rokumeikan — a banqueting hall and ballroom specially built in 1883 for the Japanese elite to entertain foreigners to Western-style balls in formal Western clothes. The balls must have been very uncomfortable for the Japanese but their purpose was very serious — to convince the long-nosed red-faced barbarians who had pushed their way into the country that the Japanese were as civilized as anyone else. At issue were the "unequal treaties"; treaties forced on the Japanese that ensured that foreigners who committed crimes in Japan could only be tried (or more often acquitted) by their own consular courts. The treaties were a source of great shame to the Japanese. In the event, a naive display of elegant manners and correct dress did not convince the foreigners that the Japanese were equals and the treaties were not revoked — rapid industrialization and military might did the trick a little later.

So much is known to every Japanese schoolchild; what the sketch shows is poor Mrs Itoh, wife of the first Prime Minister Itoh Hirobumi, worrying over what to wear, and how to dance, and what food to cook to please the foreign devils at the Rokumeikan. Of course, INS provides all the answers — instant access to video databanks through the high-speed video response system gives her dancing lessons and cooking lessons and doubtless many other insights into all our nasty habits. Information is power! The point is well made: Tokyo is these days full of foreigners clutching books on how to do business with the Japanese (and even how to hold chopsticks) and doubtless wishing there were video databanks to make it all a little less painful.

But NTT's video presentations of the future uses of INS fall short of being really convincing. A forester worried about how many trees to cut calls up an Earth resource satellite, a fisherman with access to a meteorological satellite — will it be cost-effective? With INS's more exotic applications, Japan has for once moved out in front of other nations. Will Japan discover that being a trail-blazer can also mean going the wrong way? □

Brainwaves to touch

WHY should Kodansha, a major Japanese publisher, have taken an area of 1,800 square metres at Tsukuba to build what it calls a "brain house", a multi-video explanation of how the human brain works? Because that is how people use its products, of course.

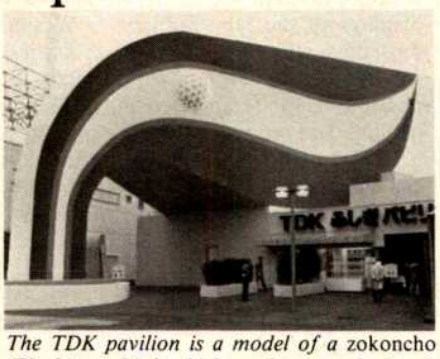
The result is an extraordinarily ambitious exercise in popularization. The designers have tried to represent what little is known of the anatomy and neurophysiology of the human brain in a series of working models; press a button and see how input to the right eye distributes signals predominantly to the left cortex, but partly to the right hemisphere. Other sensory systems, and the role of the hypothalamus and the pituitary, are similarly described. Perhaps the definiteness of the labelling (and the life-size and thus too-small models) may give visitors the impression that phrenology is back in fashion.

This sober stuff is submerged in one of the jazziest video displays at Tsukuba. The whole of a darkened dome is used to represent the way in which the networks of neurones are used in different physiological functions, while a character called Goku, derived from Chinese fairy stories but animated for these purposes, serves as an entertaining unacademic expositor.

As popularization, the pavilion succeeds in the sense of showing a lot of what is known. It conveys a sense of what remains unknown less convincingly. But it is a courageous attempt to explain a large chunk of science without promising that a host of gadgets will ensue. John Maddox

TDK pavilion

Animals getting taped



MAKING strange the ordinary abilities (or events) we normally take for granted is perhaps the first step to becoming a good scientist: one Nobel-prize winning ethologist used to advise that one should try looking around one from the standpoint of a "Martian that just arrived on Earth". The pavilion presented by TDK (the magnetic tape manufacturer) comes close to simulating that spirit. It attempts through a film to give some taste of the strange experience of perceiving the world as if through the visual, auditory and touch senses of an animal.

The idea is one that has often attracted animal documentary film makers but is notoriously difficult to carry off. TDK's attempt is at its most successful in depicting the underwater world of fish, where changes in the field of vision, depth of focus and the absence of long range are easy to simulate photographically. The world of the horse, where the visual field is extended to 320 degrees in the horizontal plane but greatly narrowed in the vertical plane, is also easy enough.

Things get much more difficult when smaller forms of life are considered, the forms of which D'Arcy Thompson wrote: "A water-beetle finds the surface of a pool a matter of life and death, a perilous entanglement or an indispensable support. In a third world, where the bacillus lives, gravitation is forgotten. We have come to the edge of a world in which we have no experience and all our preconceptions must be recast."

Alas, after attempts to see what a rainstorm would be like for a small insect — an occasional encounter with a very large object — things come seriously unstuck as the film turns to the compound eye; an extraordinary kaleidoscope of multiple images fills the screen while a voice tells one that "it is thought the brain may process the images into one" (of course, this may have been a clever in-joke for troubled insect neurophysiologists). Nor does the film find any new way round the intractable problem of modelling auditory and tactile senses, other than explaining how they are better developed in certain species.

But overall, the film just about works, and at the end it returns nicely to technology by stressing how, from the study of animals with senses superior to our own, we can learn how to build new sensors. Respect Nature and learn from it is the message, one that got lost in the multi-sensory stimulation of most pavilions. □

The TDK pavilion is a model of a zokoncho *(Elephinsect bird) which combines an elephant's trunk, an insect's compound eye and the flying abilities of a bird.*

Tokyo residents kept awake by the next-door neighbours' stereos would certainly be grateful if Matsushita can speed development of their speakers. Sound from the large circular speakers set a couple of metres above the ground can only be heard when standing within the smaller circle seen on the floor — a 50-centimetre movement of the head and all the sound vanishes. Normal sound is of too long a wavelength to be sharply focused in the same way that light can. Only ultrasound can be easily focused — but of course humans cannot hear it. So what Matsushita have done is to use two focused beams of ultrasound of slightly different frequencies. At the point of focus they interact with one another; the result of the sum and difference of the two waves is the generation of audible sound at that point only.

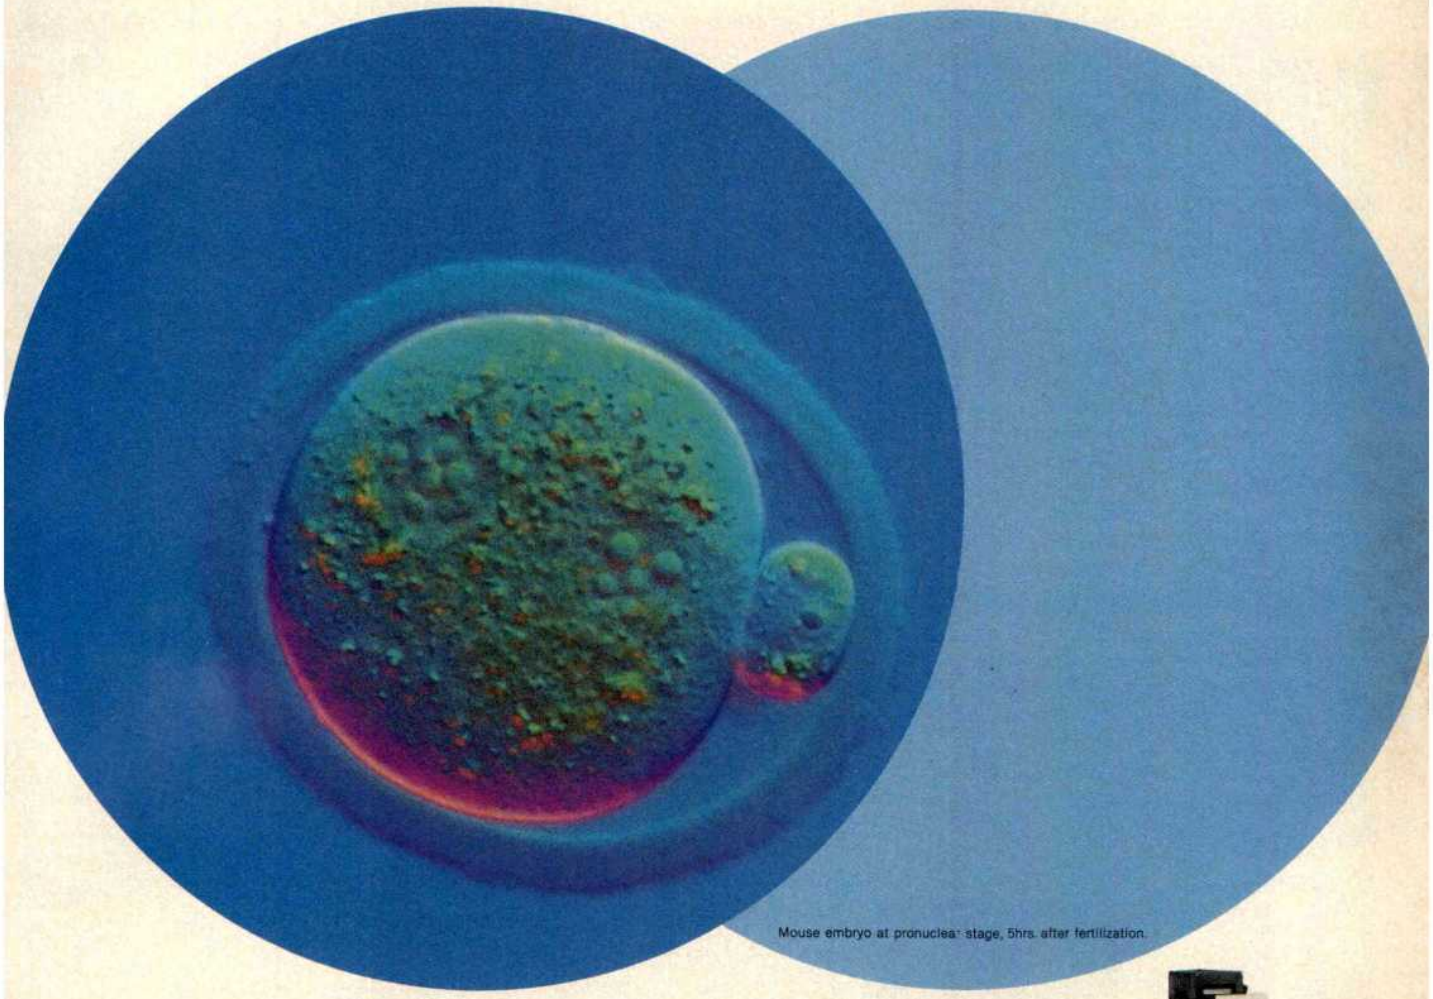
Suntory pavilion

Today birds, tomorrow men

AT last a discordant note in the hymns being sung to the boundless joys of technology at the Japanese corporate pavilions! At the Suntory pavilion not only is it acknowledged that technology can cause plenty of problems, but also that some of those problems need dealing with fast.

Suntory's must be the only pavilion to state clearly that curses have also sprung from technology: "ever worsening environmental pollution, wanton consumption of the precious blessings of Nature, a loss of concern for the protection of living things, a lack of warm regard for one's neighbours".

The pavilion's theme is "Today birds, tomorrow men", the point being made is that birds are among the living things most sensitive to changes in the environment and many have been pushed to extinction — after them it is us. To drive the point home, the pavilion employs the world's largest cinema screen and a film, concentrating on efforts to save wild birds, which contains what must be some of the best shots ever taken of wild birds in flight.



The film centres on a family of Canada geese and, in the most striking sequences, it follows them in flight across ocean and forest, partly in extreme close-up from just behind the leading bird as the flock flies in a V-shaped formation soaring across the oceans. How did the photographer manage it? A Suntory representative could say only that a special "silent glider" had been developed by a Japanese-Canadian team to allow the mid-air close-up.

To its credit, the pavilion is part of Suntory's Wild Birds Campaign, which has been running since 1973. Suntory is a large whisky manufacturer and has built bird sanctuaries at many of its plants. No doubt it is good for the corporate image, but it is good for the birds too. □

Suntory's pavilion was shaped by bending steel pipes, one by one, into catenary curves. The surfaces are meant to evoke the image of a hill and to symbolize Man's desire to regain the beauty of the natural environment of the past.

A look into the future

Mouse embryo at pronuclear stage, 5hrs. after fertilization.

Olympus microscopes bring your objectives in focus

Accuracy, superb performance characteristics and extreme versatility characterize the new Inverted Research Microscope IMT-2 and the Zoom Stereo Microscope SZH. Both from Olympus, acknowledged leader in the design and manufacture of opto-electronic precision instruments. The built-in quality and advanced design of Olympus microscope systems are the cornerstones of simple, yet accurate operation.

The IMT-2 is the most up-to-date inverted microscope on the market. It is ideally suited for micro manipulation, cell injection and other research applications, particularly in the growing field of biotechnology.

The Zoom Stereo Microscope SZH, with its innovative building block design and flat-field, highly corrected objectives, is ready to meet the diverse challenges of biotechnology and industry.

Olympus—providing you with the technology to look into the future.

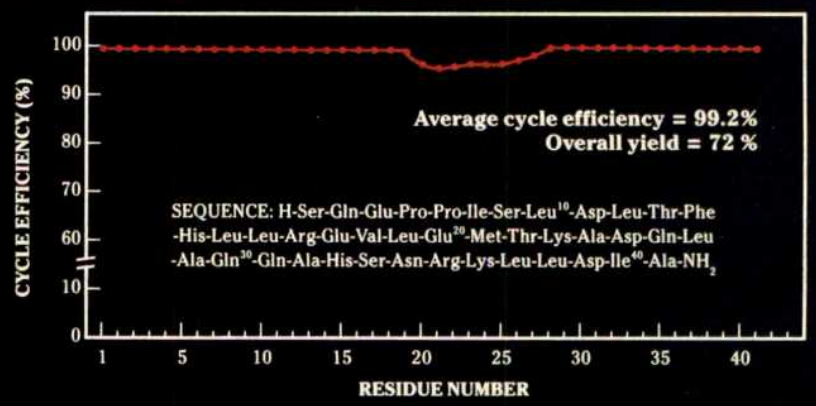
THE BIOSEARCH SAM TWO PEPTIDE SYNTHESIZER

THE INTELLIGENT CHOICE FOR AUTOMATED PEPTIDE SYNTHESIS!



The BIOSEARCH SAM TWO is the one peptide synthesizer that will satisfy the needs for all peptide research. The synthesizer's advanced design and integrated software totally automate the arduous task of peptide synthesis and deliver unsurpassed results.

Uncomplicated operation

The Sequence Driven™ software automatically calculates and scales all reagent requirements for synthesis of milligram to multi-gram quantities of crude peptide. The microprocessor reviews the desired sequence and assigns optimum coupling strategies. Synthesis of over 1000 peptides has demonstrated routine coupling efficiencies exceeding 99% for sequences of various lengths and complexities.

Proven Reliability

Exceptionally reactive complexes of the protected amino acid are formed without dilution or contamination to produce superlative coupling efficiencies. Sophisticated failsafe mechanisms protect the automated synthesis from power line failures, nitrogen pressure failures and reagent depletion.

Quantitative determination of cycle efficiency at each step during a capped synthesis of ovine corticotropin-releasing factor (41mer) on the Biosearch Sam Two Peptide Synthesizer.

Advanced, Flexible Design

The reaction vessel has been designed to incorporate non-destructive mixing and complete internal rinsing, which increase efficiency. The standard synthesis software accommodates improved t-BOC chemistry protocols, while programming flexibility allows for FMOC and other peptide chemistries.

Uniquely Supported

Our expert chemical advisors and *high purity* protected amino acids, resins and synthesis reagents support the Biosearch Sam Two Peptide Synthesizer—The ultimate in synthesis automation.

For further information on performance specifications contact Biosearch.

CERN collider seeks the Centaurs

Last Sunday the proton-antiproton collider at CERN generated the world's highest energy interactions yet, in a quest for some strange effects first seen in cosmic rays. The work should continue.

AT 1 a.m. last Sunday morning, jubilant experimenters at the European Organization for Nuclear Research (CERN) working on the UA5 detector on the proton–antiproton collider recorded their first events at 900 GeV in the centre-of-mass, the highest energy at which matter has been collided with matter (or antimatter) under controlled conditions on Earth. The object over the next few weeks will be to discover if the collisions show signs of the very-high-energy "Centauro" ("centaur-like") events first detected in a Japanese–Brazilian cosmic-ray experiment in the Andes[1] as long ago as 1972, events that appear to lack all production of photons. Centauros are unexplained and treated with scepticism by most experimental particle physicists, but if they exist — and those who have studied the data carefully say they do — they would presage a fundamental reconstruction of theory.

Hence CERN's brief gamble, which, following an idea by UA5 group leader John Rushbrooke of the Cavendish Laboratory, Cambridge, involves a complicated ramping of the bending magnet current and accelerator cavities so that the colliding beams can reach — momentarily — 450 GeV apiece. The energy can only be maintained for four seconds at a time, as the magnets would overheat at the currents required to sustain the bending of 450-GeV beams. So the beams are decelerated to 100 GeV, and then brought up again to 450 GeV a few seconds later when the magnets have cooled sufficiently. It is undoubtedly an extraordinary feat of accelerator engineering, which pushes the collider energy up nearly by half from its usual constant 630 GeV maximum in the centre of mass.

The experiment certainly is a gamble, however, and CERN is treating it as such, giving UA5 the tail-end of the electricity supply year, when by contract *Electricité de France* can cut supplies to CERN for a day at a time — and usually does. There are five such *jours critiques* left before Easter, when UA5 must shut down for good. CERN staff describe experiments at such times as "crazy runs", but Rushbrooke said on Monday that he hopes UA5 will still collect some 100,000 events.

This should be enough to see if the Centauro effect is real — provided it occurs at or below 900 GeV. UA5 has already searched at 630 GeV but found no sign of the events. In the cosmic-ray experiment on Mt Chatacaya in the Andes, however, a per cent or so of the highest energy events recorded were photon-less Centauro events. (These events appeared unusually different in the upper and lower halves of the Chatalcaya detector — hence the "centaur" designation.)

Nevertheless, all the five Chatalcaya Centauros appeared to have equivalent centre-of-mass collision energies of 1,500–2,000 GeV, and it is uncertain whether, even at its boosted 900-GeV energy, the CERN collider will reach the threshold at which the Centauro effect sets in.(It is presumably somewhere between 630 and 1,500 GeV, if the events exist at all.)

At this point CERN's competitor steps into the act — the Tevatron collider at the Fermi National Accelerator Laboratory (Fermilab) near Chicago. Already this July and August, the superconducting Tevatron will take its first trial proton and antiproton beams, and the detector designed by Roy Schwitters of Harvard University and his collaborators will begin to take data at centre-of-mass energies that should run from 800 to 1,600 GeV. "It's a shakedown cruise" and "a very ambitious goal", said Schwitters last week, to get data on the Tevatron collider so early (the first serious data were not expected before spring 1986) and "we'll be delirious with joy if we see any collisions", but the chance is there that if CERN sees no Centauros now, Fermilab may see them this summer at its higher energies, or at least by the end of next year.

UA5 is worth a gamble, however — and not only to keep up the prestige of CERN (though prestige itself is not a negligble factor, as the vitality of a laboratory depends on it). UA5 is a unique detector, containing the world's largest "streamer chamber". This visualizes tracks as streams of sparks, rather as bubble chambers visualize them as rows of bubbles, and can resolve more detail in multitrack events than many other detectors, such as those under construction at Fermilab.

If, as the cosmic-ray experiments suggest, some strange global change is going on in the track composition and multiplicities at very high energies, UA5 may be in the best position to detect it. CERN might even be well advised, if the present run reveals no Centauros, to try boosting the energy yet further in the next "crazy run" period in March 1986, by improving the cooling of the bending magnets (though that could be expensive). Fermilab, also, might do well to introduce steamer chambers to its complement of Tevatron collider equipment.

But this leaves out the question of the cosmic-ray observations themselves, and whether more can be done in that area. Undoubtedly physics smacks of the 1940s rather than the 1980s, as the events are rare and uncontrolled — as opposed to the billions of events that can be produced with tuned, intense accelerator beams. But they can be of almost unlimited energy, and still thus throw up new physics, as the Centauro events themselves indicate.

One member of the UA5 collaboration, Narendra Yamdagni of the University of Stockholm, has spent five years working with the Japanese physicists who contributed to the Centauro study, and is impressed with the evidence. This shows up not only Centauros, but also other ultra-high-energy phenomena such as "binocular" events, where the cosmic-ray collision far up in the atmosphere appears to produce two (or more) clear jets of products, and, more recently, so-called "chiron" events in which there appears to be a microscopic bunching of tracks within each jet. A Moscow collaboration working on Mt Pamir has also seen a Centauro event "even more spectacular" than the ones seen on Chatalcaya, says Yamdagni.

Yamdagni has now left cosmic-ray work to experiment on UA5 and the large electron collider (LEP) at CERN, but he strongly recommends that cosmic-ray research should be amplified, perhaps by flying 1-ton cosmic-ray experiments in routine passenger-carrying jumbo jets. "Their payload is 50–70 tons" says Yamdagni, "so it should be possible to accommodate a ton".

Cosmic-ray intensities in the stratosphere are 40 times those obtainable deeper in the atmosphere on Mt Chatalcaya, Yamdagni points out. Moreover, within a one-ton experiment, equipment (such as proportional chambers) could be included to make results less ambiguous than at present. It would also make them more acceptable to sceptical particle physicists. Japan Airlines are already flying, free, 20-cm-cube detectors designed by the Waseda University group that helped find the Centauros. Perhaps they should be 125-fold more generous, and extend the dimensions to a metre. **Robert Walgate**

Publications

Variations on a theme

from Jared Diamond

WE SCIENTISTS have chosen a cruel profession. To advance, we must publish, but our best works are often rejected, published in mangled form, ignored, or criticized. We must publish a lot, but not by plagiarizing the work of others nor by recycling our own material. While chasing grants, claiming priority for discoveries, and currying academy memberships, we risk missing deadlines, being passed over for appointments, or getting fired. We suffer grievously from politics, and few of us get rich. Worst of all, only a short span of productivity remains to us from the time we complete professional training until our creative powers wane. How are our problems to be solved? On the occasion of the 300th anniversary of Bach's birth (21 March 1685), what perspective can be gained from the way great composers faced these problems?

Incomprehensibly to modern scientists, desperate to amass long lists of publications, Bach never bothered to publish his B minor mass, St Matthew and St John passions, and Brandenburg concerti, which rank today among the monuments of western culture. Those works survived in manuscripts; his great C minor fantasia and fugue survived in a single copy, supposedly rescued from a pile of wrapping paper in a Leipzig shop; but his St Mark passion and dozens of cantatas mentioned by his contemporaries disappeared.

Other composers, eager to get their works published and decently produced, have encountered difficulties that are familiar to scientists. A few weeks before Schubert's death, four of his greatest works — the C major quintet and the last three piano sonatas — were rejected in one letter from the Leipzig publisher H.A. Probst, Beethoven's violin concerto was premiered without a rehearsal, and the soloist (one Franz Clement) interrupted it to play his own sonata, on one string with the violin turned upside down. Verdi could not complete *Aida* in time for the deadline (to celebrate the opening of the Suez Canal).

As for plagiarism, Mozart's requiem was commissioned by Count von Walsegg zu Stuppach, who liked to order works from professional composers and produce them as his own. The art of recycling works of one's own and others was honed to perfection by Bach and Handel. Of Bach's fourteen concerti for harpsichord, not more than two are original, while the Christmas and Easter oratorios were mostly lifted from his cantatas. Scientists have lost their jobs for far less extensive recycling.

Virtually all great composers have been exposed to vicious criticism. Berlioz despised Bach's music; Debussy, Fauré and Dukas walked out on Mahler's conducting of his second symphony; Weber viewed Beethoven's seventh symphony as evidence of insanity; Brahms compared Bruckner's symphonies to endless serpents; and a critic likened Pasatieri's music to a "stream of perfumed urine". Compared with such metaphors[1], the invective of the most pugnacious modern biologists — the cladistic taxonomists and vicariance biogeographers — is unimaginative (for example, "Darwin preached from ignorance"[2]). Like the research of Mendel and Wegener, Ives's work found widespread approval only after his death.

Disappointments in the quest for positions and honours have loomed as large for musicians as for scientists. Through servile letters, Bach managed to wheedle the honorary title of royal court composer out

"... I am afraid we shall only be able to publish your manuscript if it is cut by ten bars..."? (British Library).

of the Elector of Saxony. Other composers suffered crushing rejections. Few scientists take the loss of an NIH grant as hard as Tchaikovsky took the termination of his 14-year grant from the widow Nadezhda von Meck; he wrote bitterly that her name would be found carved in his heart when he died. To the end of his life, Brahms remained deeply wounded by the action of the Philharmonic Orchestra in Hamburg, his birthplace, in passing him over at the age of 30 as conductor. Schumann was compelled to resign as conductor at Düsseldorf, while the Vienna Opera fired Mahler in 1907 and Richard Strauss in 1924. A worse fate nearly befell Haydn, who as a teenager narrowly escaped castration by a choir director eager to preserve his soprano voice.

One might suppose a musician's career to be free of the problems of priority that are commonplace to scientists; a race to isolate the AIDS virus, yes, but surely not to compose the B minor mass? In fact, the shortage of suitable libretti has provoked scrambles among opera composers rivalling that which pitted Pauling against Watson and Crick. Leoncavallo, who apparently wrote an operatic libretto based on a novel by Mürger and showed it to Puccini in 1893, was enraged to learn from Puccini over lunch in 1894 that he was busy at work on a rival libretto. Newspapers reported both composers' intentions that night, and the race was on. Puccini won by 15 months; he also wrote the better version of *La Bohème*.

Like great scientists, few great musicians become rich, and fewer still are shrewd enough to retain their riches. Bach's Brandenburg concerti were sold after his death for four gröschen apiece; Beethoven lost money on the premiere of his ninth symphony. Brahms eventually was able to sell his compositions for high fees but foolishly entrusted management of his money to his publisher Simrock, who lost heavily in stock market speculation.

Musicians have had even less success than scientists at using their talents for or against political causes. Prokofiev dutifully composed a cantata, *Hail to Stalin*, and was named People's Artist of the Soviet Union, but lived to see his works banned, like those of Lysenko's rival, the geneticist Vavilov. Shostakovich fell from official grace and regained it with his fifth symphony (subtitled "A Soviet Artist's Reply to Justified Criticism"), only to fall again.

Comparisons between scientists and musicians are especially instructive for psychologists studying how human creativity develops with age[3-7]. Creativity tends to flower and fade early in fields that require reasoning skills rather than varied knowledge, but late in fields requiring one to unite disparate data. Thus, pure mathematicians and molecular biologists peak in their twenties and thirties but evolutionary biologists peak much later. Darwin published *On the Origin of Species* when he was 50, and produced seven major books in the eleven years up to his death at 73, while Ernst Mayr recently completed his monumental *The Growth of Biological Thought* (Harvard University Press, 1982) at 78. Musicians, of course, are famous for precocity but it is less appreciated that most great composers, except Sibelius, continued to be creative until felled by illness or death. Composers whose music unites words, voice and instruments particularly tend to peak very late in life — they are the evolutionary biologists of the musical world. Haydn, Janacek, Lalo and Rameau produced their greatest operas, oratorios, or masses between the ages of 65 and 72. Verdi's masterpieces *Othello* and *Falstaff* were completed at 74 and 80, while Richard Strauss's poignant and richly orchestrated

Erratum

In the fifth paragraph of Ian Stewart's article "How bent is a knot?" (14 March, p.130), the sentence beginning "If $n = 1$ (M is a curve)" should have continued "then $4\sigma_1$ must be replaced by $2\sigma_1$. And if $n = 3$, $N = 4$, then σ_1 is replaced by...".

Four Last Songs, looking back on his long happy marriage and its impending dissolution by death, were written at 84. By contrast, I am unaware of any Nobel Prize awarded for work done after the age of 65.

Do the changes in the creative style of composers with age offer a message for scientists aware of shifts in their own creativity? The desire for recognition often drives scientists cruelly to demand of themselves a time scale of creative development that their subject matter does not permit. It is not easy for young evolutionary biologists to be patient, nor older molecular biologists to be satisfied with an enforced change of intellectual goals as they age. Many composers confronted with similar problems were able to find inner peace. Richard Strauss, like his equally precocious librettist Hugo von Hofmannsthal, remained creative to the end, but was well aware of, and adapted to, changes in his abilities. No longer able to spin out the long musical phrases that had marked the symphonic poems of his youth, he turned instead to operas based on much shorter themes. The published correspondence of Hofmannsthal and Strauss[8] will fascinate scientists concerned with mastering the problems of publishing or perishing as they grow older. They might also bear in mind that as his total output (especially of sacred contatas) shrank with age, Bach concentrated on his two contrapuntal masterpieces, the *Musical Offering* and *Art of the Fugue*. □

Nuclear structure

Taken with a grain of salt

from Virginia A. Zakian

THE cytoplasm of eukaryotic cells is permeated by a highly-ordered subcellular skeleton of filaments and membranes. Even non-structural cytoplasmic components such as glycolytic enzymes are firmly positioned within this three-dimensional array. It would not, therefore, be surprising if the nucleus possessed an organizing skeleton required for the proper positioning of sequences important for replication, transcription, and chromosome integrity. Indeed the appearance of chromosomes at cell division as well as recent studies on polytene chromosomes in *Drosophila* interphase nuclei[1] provide cytological evidence for nuclear order. A variety of biochemical studies also support this view, including the isolation by Laemmli and co-workers of what they call the nuclear scaffold[2-5]. In a recent paper, this group has explored the nature of DNA sequences associated with the scaffold in *Drosophila* cells in interphase and asked whether these associations change as a function of gene transcription: their answer is provocative.

It is still a matter of controversy whether a nuclear substructure exists at all. Scepticism centres on the methods used to prepare material suitable for biochemical analysis: because there is no assay for structural integrity, it is difficult to prove that interactions found in intact nuclei are maintained during isolation. Of the different procedures developed to probe nuclear substructure, the isolation of the nuclear matrix is the most widely used. The matrix is defined as the largely proteinaceous structure which remains after isolated nuclei are extracted with non-ionic detergents and high-salt (2 M NaCl) and then digested with DNase[6]. Prior to the digestion, chromosomes are attached to the matrix at multiple sites such that the DNA is organized into topologically-independent, supercoiled domains[7]. After DNase digestion, the matrix retains the approximate shape of the nucleus and exhibits three major ultrastructural features: an outer lamina, a residual nucleolus, and a fibrillar network.

There is little consensus as to the nature of the DNA sequences involved in attachment to the matrix: some reports indicate that it is a random subset of the genome whereas others find an enrichment for repetitive sequences or specific genes. But a number of studies in a variety of systems suggest that the matrix provides a structural support for DNA replication, in that newly synthesized DNA is tightly associated with the matrix (see, for example, ref.7). Moreover, many workers find that structural genes are preferentially associated with the matrix in cell types in which the gene is actively transcribed (see, for example, ref.8). For some investigators these data are sufficient to indicate that the matrix serves a crucial role in organizing nuclear events; for others, they are artefacts of isolation, in that exposure of nuclei to high salt could induce precipitation of proteins or transcription complexes onto the matrix as well as allow sliding of DNA attachment sites.

Although the relationship between the nuclear matrix and Laemmli's nuclear scaffold is not clear, they share certain structural properties: for example, a subset of nuclear proteins is common to both and both include the peripheral nuclear lamina. The scaffold is prepared from the metaphase chromosomes of mammalian cells by the depletion of their histones and most other nuclear proteins, leaving a proteinaceous axial structure which retains the approximate shape of the original chromosome and is surrounded by a halo of DNA loops[2]. A rapidly-sedimenting structure with similar biochemical properties has been isolated from interphase cells[3]. The scaffold from both mitotic and interphase cells is sensitive to disruption by chelation and is believed to be held together by metalloprotein interactions[4,5].

For their recent investigation of the scaffold-associated DNA sequences in *Drosophila* interphase cells, Laemmli's group has developed a gentle, low-salt procedure of nuclear lysis. Isolated nuclei are extracted with buffers containing spermidine and lithium di-iodosalicylate (LIS), a salt with detergent-like properties which can be efficiently removed after use. These histone-depleted nuclei are washed, pelleted, and digested with restriction enzymes which solubilize about 70 per cent of the DNA. Both the solubilized DNA and the DNA in the residual nuclear scaffold are then assayed for the presence of specific sequences, including fragments of histone and heat-shock genes.

When fragments derived from the five-kilobase histone gene repeat unit are examined, one fragment is found exclusively with the scaffold whereas all the other fragments are found primarily in the supernatant. The scaffold-bound fragment is rich in adenine and thymine (A + T) and is derived from a non-transcribed 'spacer' sequence upstream of the histone 1 gene. Likewise an A + T-rich fragment from the non-transcribed spacer of the *hsp70* heat-shock genes is scaffold-associated. Moreover, this association is independent of the transcriptional state of the *hsp70* genes. Finally, many copies of a middle-repetitive A + T-rich element, including a copy found upstream of the *hsp70* gene, are scaffold-bound. These results suggest that the DNA loops of interphase nuclei are maintained through sequence-specific associations with scaffold proteins and that these associations do not change as a function of transcriptional activity. None of the specific associations are maintained if LIS-extracted nuclei are treated with 2 M NaCl after digestion with restriction enzymes. One interpretation is that a high concentration of salt disrupts the specific DNA-protein interactions in the scaffold; at the

same time it induces non-specific associations of active-gene regions through precipitation of transcription complexes[5].

These results are provocative: although they support the hypothesis that the nucleus is highly ordered, they raise doubts about the validity of methods widely used to analyse nuclear structure. However, in the absence of an accepted assay for structural integrity, this report must be evaluated with caution. It is possible that the LIS-extraction procedure introduces its own artefacts: for example, it might induce precipitation of A + T-rich sequences on to the residual scaffold. It is also possible that there are different classes of DNA-protein associations in intact nuclei, only some of which are transcription-dependent and only some of which are maintained through different isolation procedures. For example, it is easy to imagine that DNA interactions with the peripheral lamina will display a different sensitivity to extraction conditions than do interactions with the internal fibrillar network.

The argument against high-salt methods for the study of nuclear structure will be strengthened if others obtain similar results in different systems. Convincing proof of the importance of a given nuclear substructure may ultimately require the identification of mutations in its components; investigations in a lower eukaryote, amenable to genetic analysis, may be the most profitable way to establish functional basis for nuclear structure. □

Magnetochemistry

How many atoms make a metal?

from D. Michael P. Mingos

MAN'S ability to recognize and exploit the characteristic properties of metals has been an important part of his technological development, although the magnetic and electrical properties of metals have only been fully utilized in the past hundred years. The scientific interpretation of these characteristics is based on a band-theory model, which raises the question of whether the characteristic properties of a metal are still displayed by the molecular clusters containing as few as 10 - 100 metal atoms that have been synthesized in recent years. The paper by D.C. Johnson *et al.* on page 231 of this issue examines transition metal cluster compounds and suggests that certain magnetic properties that they are characteristic of the bulk metal begin to appear when as few as ten metal atoms are present.

The band-theory model describes a metal as an infinite and regular three-dimensional array of atoms where electrons are no longer localized but are shared between the constituents, which are thus able to respond cooperatively to external forces. Ideally, studies on emergent metallic properties should be carried out on small-diameter particles (5 - 100Å) but these pose severe experimental and technical problems. First, such particles do not all contain the same number of metal atoms but have a statistical distribution of sizes. Second, to avoid contamination by oxide species, it is necessary to study them under high vacuum conditions.

The strategy adopted by Johnson and his colleagues avoids these difficulties by investigating molecular cluster compounds of osmium, composed of 3 - 10 atoms, that are held together at distances comparable to those found in the bulk metal. These clusters have a small chunk of bulk metal at their centre, but each metal atom is also bonded to carbon monoxide molecules, which stabilize the cluster and provide a protective sheath to stop the cluster aggregating into particles of bulk metal. Such cluster compounds have been synthesized in large numbers in recent years, particularly by research groups in Cambridge and Milan, and have been structurally characterized by single-crystal X-ray techniques. As a result, well-characterized compounds with fixed numbers of metal atoms and high purity are now available in reasonable quantities. They are generally air-stable and highly-coloured crystalline solids.

Johnson *et al.* have measured the magnetic properties of these compounds using a high sensitivity computer-interfaced Faraday magnetic balance in the temperature range 1.5 - 300 K. The compounds show a temperature-independent paramagnetic susceptibility, which is not surprising since, in a formal sense, all the electrons are paired up in metal-metal bonds. The observed paramagnetism arises from excited states that are not thermally accessible. The interesting aspect of the results arises from a positive correlation between the observed paramagnetism and the number of metal atoms in the cluster. They argue that the paramagnetism increases in this sequential fashion because molecular electronic states begin to develop into the band and continuum states that are characteristic of the bulk metal. The number and energies of the excited states increase with the number of metal atoms in the cluster, as demonstrated by a red shift in the electronic spectra, and consequently they make a larger contribution to the observed paramagnetism. This leads them to predict that transition-metal cluster compounds containing more metal atoms may show very interesting electronic properties that arise from a polarization catastrophe within the clusters themselves.

The authors are more equivocal in their answer to the fundamental question of how many atoms are needed in a cluster to mimic effectively the bulk properties of a metal. This depends on the particular property being measured. Transport properties, such as electrical conductivity, require complete ionization of electrons from the parent site — a process which might require 0.1 - 10 eV. — before metallic character can be detected. Magnetic properties, in contrast, are observed for clusters with quite small numbers of metal atoms, because modification of the intra- and inter-unit exchange energies requires only about 10^{-3} eV.

An industrial chemist is more likely to want to know how big the cluster need be before it performs effectively and selectively as a catalyst in a chemical reaction, a question that cannot be answered by this type of magnetic measurement. Chemists have, however, now synthesized molecular clusters with up to forty metal atoms, so no doubt they will soon be able to design suitable experiments to answer this question. □

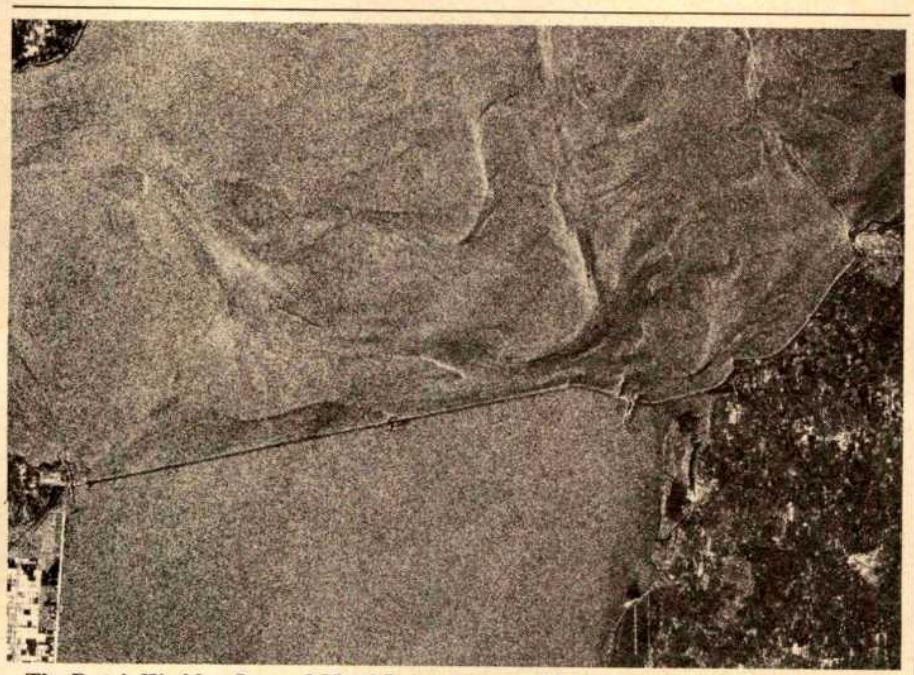
Satellite oceanography



Radar images of the sea bed

from J.F.T. Zimmerman

SINCE G.P. De Loor first observed sand-wave-like features in radar images of the sea surface[1,2], the SEASAT satellite has produced many examples of the radar imaging of bottom topographic features[3,4]—as in the accompanying figure. Whether taken from side-looking airborne real-aperture radar (RAR)[1,2] or satellite-borne synthetic radar (SAR)[3,4], at first sight a sea bottom topographic image is something of a mystery. In a recent paper[5] (see also page 245 of this issue[6]), Alpers and Hennings have given a firm theoretical foundation to the most likely solution of the mystery.

The images may seem to be mysterious for two reasons. First, radar waves do not penetrate into the sea for more than a centimetre, so no direct reflectance from the bottom is possible in waters which may be up to some decametres in depth. Second, since radar backscattering from the sea surface occurs primarily by first-order Bragg-scattering[7] (on account of short surface

windwaves with a wavelength half that of the horizontal component of the radar wavelength — of the order of several centimetres to decimetres) and since, as a rule of thumb, surface waves do not 'feel' the bottom when the water depth exceeds half the wavelength, the Bragg-resonant surface waves cannot form an image of the bottom topography in any direct way. So, from the outset it has been clear that it is necessary to find at least one extra link, connecting modulations in the amplitude of the scattering surface waves to fluctuations in water depth. Although several hypotheses have been raised for this missing link, one has always been a strong candidate. It invokes the modulation of the (tidal) current velocity field by the bottom topography, the resulting spatial variability of the current velocity field in turn modulating the energy density of the relevant part of the surface wave spectrum[8]. It is this mechanism that has now been given a firm theoretical basis by Alpers and Hennings[5].

The Dutch Wadden Sea and IJssel Lake, separated by an enclosure dyke, as viewed by SEASAT-SAR. Whereas the Wadden Sea has strong tidal currents, the dyke excludes them from the IJssel Lake. The tidal channel system in the Wadden Sea is clearly visible but the relict tidal topography in the IJssel Lake is not visible due to the absence of tidal currents. (Courtesy National Aerospace Laboratory, Amsterdam).

Their contribution arises from a synthesis of theoretical results aleady obtained for the various interactions between electromagnetic (radar) waves, surface waves, tidal currents and bottom topography. For the modulation of tidal currents by the sea bed, the simplest possible approach is followed, resting on two assumptions. One is that there is divergence-free volume transport, which gives an inverse relationship between the cross-isobath velocity component and the water depth; the other is that the along-isobath velocity component is independent of position. Although the latter may be an oversimplification in the light of velocity-current interaction theories[9,10], the former is certainly justified for topographic length scales that are small compared with the tidal wavelength. Thus any tidal current with a velocity component in the direction of the local bottom slope produces divergences or convergences in the velocity field. As Alpers and Hennings show, these velocity gradients can produce images of the slope of the sea bed (rather than the depth itself) in two ways, one of which applies only to SAR and the other to both SAR and RAR.

The first mechanism is, in fact, an artefact of the SAR imaging process, called 'velocity bunching'. In the absence of currents, the azimuthal (along-flight) position of a SAR target is determined by the vanishing of the Doppler frequency shift when the target is at a right angle to the flight direction. When the target moves with a current having a component in the radial direction of the radar beam, an additional Doppler shift is produced so that the target is given a false position in the image in the azimuthal direction. In the presence of gradients in the radial velocity, targets are differently misplaced causing the otherwise homogeneous grey tone to show areas of dark and light colouring according to the sign of the velocity gradient, which in turn is related to the bottom slope.

Alpers and Hennings estimate the strength of this process to be nearly an order of magnitude weaker than the second mechanism, which involves the hydrodynamic interaction between the Bragg-resonant surface waves and the tidal velocity field. Two ingredients of surface-wave theory[11] are relevant to this mechanism. Waves propagating at the sea surface in a nonhomogeneous horizontal current-velocity field experience both refractive effects and an energy exchange with the current-velocity field due to the wave-radiation stress working against the strain-rate of the velocity field. This causes the wave energy density to increase when the current velocity increases in the direction of propagation, and *vice versa*.

This, in itself, would provide a mechanism of imaging but a second process also plays an important part. The short Bragg-resonant surface waves are located in that part of the wavenumber spectrum that is called 'saturation range'. This denotes the quasi-steady state in which a delicate, but poorly understood, balance between wind-forcing, nonlinear interaction among different wave components and dissipation by wave breaking maintains a spectrum in which the energy density falls with the fourth power of the wave number. So, if the straining of the velocity field perturbs the energy level of a certain wave component in the saturation range, one may expect this component to relax to its original value either by enhanced breaking (in the case of oversaturation) or by feeding upon the wind (in the case of undersaturation). Alpers and Hennings choose to parameterize this process by simple linear relaxation, characterized by a relaxation time scale that is of the order of a minute at most, and is short compared with the time (of the order of 5–60 minutes) that the waves need to travel over a typical bottom surface. The perturbation in energy density level for a specific location is given by a simple balance between the forcing due to the strain-rate of the velocity field and the relaxation process, and so it is proportional to the velocity gradient. This, in turn, is proportional to the bottom slope (divided by the square of the depth), so the energy density of the scattered waves — and thus the intensity of the radar signal — is largest on the downstream side of the ridge and smallest on the upstream side. As a consequence, when the current flows in opposite directions during the ebb and flood of the tide, a sign reversal of the image intensity should occur, which is indeed observed in RAR images[1,2]. This, together with the estimated relative strength of image-contrasts (20–30%), represents a firm corroboration of the theory.

Evidently, the theory also applies to the imaging of any other phenomenon that causes velocity divergences or convergences at the ocean surface — for instance, internal waves, trapped at strong vertical density gradients in the ocean interior, produce an undetectable vertical displacement at the ocean surface. Such waves have shown up in radar images and again can be explained by the stretched formalism[6].

Successful as the theory may look, it rests on some drastic simplifications, in particular on the form and strength of the relaxation mechanism. This is clearly brought out by comparing the paper of Alpers and Hennings with that of Phillips[12], which runs more or less along the same lines, albeit without a discussion

of topography-current interactions. The basic difference is that Phillips uses a more sophisticated parameterization of the relaxation. He stresses the fact that return to equilibrium by wave breaking in the case of oversaturation can be a more vigorous process than feeding upon the wind in the case of undersaturation. This may lead to strong asymmetry in the imaging process even in cases where the imaged current-velocity field has a symmetrical shape itself. Under certain conditions this leads to remarkable deviations from the results of Alpers and Hennings. For instance, when a local divergence of the velocity field decreases the wave-energy density, return to equilibrium may be so slow that the actual balance is not between straining and relaxation but between straining and advection. In this case, it is not the gradient of the current but the current velocity itself that is imaged by the radar (not the slope of the bottom but its inverse depth). For convergence, on the other hand, the relaxation of oversaturation by wave breaking may happen so quickly that excessively large strain rates are necessary to produce sufficient image contrast.

Although observations seem to support Alpers and Hennings, it is no surprise that careful observations of the relevant physical parameters in tidal areas are recommended in both papers to settle the dispute over the relaxation time scale. Perhaps this is a pious wish — but both off the Dutch coast in the southern North Sea and at the Nantucket shoals near Massachusetts[13], experiments have been set up to tackle these questions. □

Blood volume regulation

On the right lines at last?

from W.E. Balfour

A WELCOME and secure step in our understanding of body fluid regulation is reported by Lang and his colleagues from Heidelberg on page 264 of this issue[1]. Their experiments on the rat heart show that a peptide is released from the atria in response to stretching in the isolated heart, or to expansion of blood volume in the intact animal. Since the peptide is one of the recently characterized atrial natriuretic factors that regulate fluid excretion by the kidney, the fluid regulation control loop between heart and kidney is confirmed.

The idea that blood volume is hormonally controlled is not new[2], nor is the possibility that low pressure elements of the heart can sense the fullness of the circulation[3]. What is new is that the heart atria contain secretory granules, the contents of which are released in response to stretch rather than depending on an automatic reflex. Lang *et al.* have shown these effects by using a radioimmunoassay developed after the atrial peptides had been isolated and synthesized[4]. The atria contain an immunoreactive molecule which is larger than that secreted in response to a stretch. Lang's group stretched the atria in two ways: by small increases in perfusion pressure in the vena cava of the isolated heart, and by expanding the blood volume by injection of graded quantities of saline in the intact animal. In each case, the response is a graded release of relatively large amounts of atrial peptide, which has a short half-life.

Unfortunately, the renal response was not measured by Lang *et al.* There are, however, two groups of experiments which do include a renal response; they are focussed on the left rather than the right atrium, but few would dispute that blood volume expansion raises the pressure in both atria. Linden's[5] experiments dissect the functional components of the response to distension of the left atrium, brought about by inflation of balloons, in anaesthetized dogs. The renal response, requiring an intact vagus nerve, is an increase in water excretion, which, in the short term of these experiments, does not result in any substantial correction of the plasma volume, the expansion of which is simulated by the balloon. Ledsome[6] has recorded similar reversible changes together with a fall in plasma vasopressin concentration, a result which is consistent with the hypothesis that atrial distension leads to a water diuresis.

On the othe hand, Kaczmarczyk *et al.*[7], working with surgically-prepared, yet conscious, trained and confident dogs, have used three stimuli to raise the atrial pressure and thus to effect a brisk increase in the excretion of both salt and water. Two of the stimuli, intravenous saline loading and ingestion of a sodium-containing meal, are just as effective after denervation of the heart, whereas stimulation by mitral stenosis, which raises only the left atrial pressure, is not effective after denervation. It is of particular interest that all of these effective stimuli are associated with a fall in the concentration of plasma renin. Only the stimulus of mitral stenosis is prevented by denervation of the heart.

More recently, Lee *et al.*[8], also working with conscious dogs, have shown that partial constriction of the ascending aorta fails to provoke the release of renin, even though the downstream fall in arterial pressure is similar to that which would be effective if the descending aorta were constricted. Constriction of the ascending aorta raises the left atrial pressure which inhibits renin release, probably through a hormonal mechanism. Thus, in these manoeuvres, increasing atrial stretch reduces the plasma concentrations of both renin and, it seems, vasopressin. The crucial question is whether these changes are causally related to the renal elimination of sodium and water in the proportions required for volume correction.

There have been few studies describing how atrial natriuretic factor causes natriuresis and diuresis. The reported potency of the peptide varies widely. This is probably related to whether the animals are conscious or anaesthetized, hydrated or dehydrated, sodium deficient or replete. Much less material is required if the renal artery is the route of administration but, so far, only anaesthetized animals have been used.

Two renal effects of atrial natriuretic factors — vascular and renin-reducing — have so far been recognized. The first is a specific reduction in renal vascular resistance[9], associated with which is an increase in renal papillary plasma flow[10] as high as that observed in rats congenitally lacking vasopressin (Brattleboro rats)[11]. Such increases in renal medullary plasma flow would be expected to dissipate (as they do in Brattleboro rats) the medullary osmotic gradient, which is a prerequisite for the excretion of a copious isotonic urine. Brattleboro rats, or rats whose blood vasopressin concentration is low from having recenty drunk water, excrete an isotonic urine at rates as high as one ml min^{-1} in response to maintained blood volume expansion[12].

Urine flows of one ml min^{-1} represent such a large recovery of the glomerular filtrate that they can be achieved only at the expense of a reduction in the normal level of fluid reabsorption in the proximal tubule. It is possible that the second action of atrial natriuretic factor — reducing renin secretion — is important here. Proximal-tubule puncture studies in rats whose renin-generated angiotensin II levels have been reduced by captopril, show a marked reduction in sodium reabsorption[13], and Shirley[14] has argued that the increased sodium excretion seen on captopril treatment of anaesthestized Brattleboro rats is likely to be a proximal-tubule effect.

The distal tubule has a much smaller role to play in the control of natriuresis,

particularly in short-term volume control, although it can become important as a fine control mechanism in the longer term. It is interesting that the angiotensin II-stimulated release of aldosterone from adrenal glomerulosa cells[15-17] can be inhibited by physiological amounts of the atrial factor and that avid receptors for the atrial peptide have been found in kidney tubules in smooth muscle of the vasculature and in glomerulosa cells[18].

It is necessary to ask whether the fall of both plasma renin and of vasopression exerts a regulatory or permissive role on the excretion of salt and water. This will not be answered until there have been measurements matching the observed changes in the concentration of atrial factor in the plasma to the different sensitivities in the control of the secretion of these two hormones. There is a long way to go before we can emulate Verney's observation[19], in the allied field of water balance, that a one per cent rise in the osmotic pressure of blood going to the brain is sufficient to produce a maximal antidiuresis. □

Solid state dynamics

Unsolved problems of creep

from J. Weertman

ON page 255 of this issue Doake and Wolff[1] bring new information to a very intriguing, unresolved problem in high temperature creep of crystalline solids. The outcome of their examination of creep flow of ice in polar ice sheets is of importance not only to glaciers but to the deformation of the Earth's mantle and, of course, to the understanding of the creep process itself.

The origin of the problem is the old observation by Harper and Dorn[2] of a creep rate that is proportional to the applied stress (Newtonian creep) in aluminium at relatively low stresses, in conditions such that the creep should be produced by dislocation motion and so is expected to be proportional to a power of the applied stress. This expectation arises from the fact that creep rate is proportional to the product of the dislocation density and the average dislocation velocity. The former quantity, in steady state, is proportional to the stress squared and the latter to the stress. Hence the creep rate is proportional to the cube power of the stress. (Higher powers are also possible[3,4].)

It was easy to dismiss the original Harper-Dorn experiment by claiming that steady-state creep had not been attained. The initial dislocation density in material that shows decelerating creep before steady-state creep is reached is higher than when steady-state conditions prevail. If the creep rate is measured only in a small initial strain region, the dislocation density may be approximately a constant during the course of creep experiments. Hence the creep rate falsely seems to be proportional to stress. Very recently, Soliman and Mohamed[5] have shown experimentally that this applies to the original Harper-Dorn experiment and to more recent experiments that were not extended to large strains. It does not, however, apply to experiments in which Harper-Dorn creep has been measured in metals with large strains[6].

Blacic and I[7] recently offered an explanation of Harper-Dorn creep that has yet to be tested experimentally. We pointed out that the temperature cycling that is inevitable in the usual high-temperature creep tests is sufficient to produce large chemical stresses on the dislocations by periodically altering the value of the equilibrium-point defect density. Hence the dislocation density can be controlled by the chemical stress rather than by the applied mechanical stress. The average dislocation velocity remains proportional to the applied mechanical stress and the creep is Newtonian. This explanation, that Harper-Dorn creep is an artefact of temperature cycling, does not work for Harper-Dorn creep of ice in glaciers and in polar ice sheets, because seasonal temperature fluctuations are effectively removed at depths greater than about ten metres. (This has also been pointed out by Lliboutry and Duval[8].)

Nor, for the same reason, does it work for Newtonian creep in the Earth's mantle. Glacial rebound data and the anomalous motion of satellites orbiting the Earth are very nicely accounted for by analyses of mantle deformation that are based on Newtonian creep for the mantle[9,10]. Moreover, Harper-Dorn creep has been observed by Poirier *et al.*[11,12] in a mineral analogous to one of the presumed major minerals of the lower mantle.

If Harper-Dorn creep is real, and not just a peculiar experimental artefact, life is made easier for modellers of both mantle flow and glaciers. They can use the simpler linear constitutive law in their work. But the rub is that transient creep still cannot be ruled out as the explanation of the evidence for mantle and glacier Harper-Dorn creep. The creep strains that are involved in the analysis of both glacial rebound and anomalous satellite motion are generally quite small. Hence it is still possible to dismiss the application of these results to convection currents in the mantle, where clearly the strains are quite large.

As pointed out by Doake and Wolff[1], the measurements they analysed may also involve non-steady-state creep. The tilt of boreholes gives the creep rate as a function of depth, but the shear stress also increases with depth. To have steady-state creep, the stress must remain constant. Their results can be accounted for either if ice at moderate stresses is indeed Newtonian or if transient creep effects make it appear to be Newtonian although it is not. The same is true of the evidence that indicates Newtonian mantle creep. To help resolve this problem, it would be well worth obtaining the spreading rate of the Ward Hunt Ice Shelf in the Canadian Arctic. This ice shelf is much thinner than the Antarctic shelves considered by Doake and Wolff, and should give another, large creep-strain datum point at a much lower stress level. If ice is Newtonian and if it can be shown that temperature cycles do not account for Harper-Dorn creep in laboratory experiments, the very interesting phenomenon of creep in crystalline solids will remain to be solved. □

Protein engineering

Hydrogen bonds in active sites

from John Galloway

SINCE the sceptical reception of Latimer and Rodebush's suggestion in 1920 that they hold water molecules together, hydrogen bonds have come a long way. They are now widely believed to play the definitive role in determining molecular specificity. Hence the interest of protein engineers in hydrogen bonds and the paper on page 235 of this issue in which Alan Fersht and colleagues analyse, by means of systematically altering the amino acids of the active site of an enzyme, the hydrogen bonds that determine substrate specificity.

Full realization of the potential of protein engineering is some way off. The chief problem is our inexact understanding of the energetics of the three-dimensional structures of proteins and of the relationships between those structures and the proteins' functions. It is well enough established that the sequence of amino acids uniquely defines a protein's three-dimensional structure and, in doing so, confers on it a capacity to interact functionally with perhaps only one other molecule. Driven to the molecular level, the study of biological specificity thus becomes the detailed analysis of this structural and functional idiosyncracy and the mechanisms by which it is achieved.

Without a detailed understanding of the way proteins are put together, it is inconceivable that new proteins can be designed or old proteins given new roles. But that understanding is hard to win in the degree of detail needed, and the capacity to determine structure and function by protein crystallography still far outstrips any attempt to predict it from amino-acid sequence. It may become possible to mimic protein folding by analogue means but otherwise we are left with energy calculations which are not easy. Although, among other things, fair calculations can be done '*in vacuo*', proteins fold in water, which probably mediates all interactions of any interest. Since it is now possible to change any residue in a protein by site-directed mutagenesis of its gene, the present compromise is to study empirically the structural and energetic changes associated with small changes in amino-acid sequences.

For Fersht *et al.*, the protein under study is the enzyme tyrosyl-transfer RNA synthetase which activates tyrosine, forming a complex between the enzyme and the intermediate tyrosyl-adenylate, before transferring the amino acid to its transfer RNA. (The enzyme is of no apparent medical or commercial interest.) The power of the approach lies in combining site-directed mutagenesis both with enzyme kinetics, which gives accurate estimates of changes in binding energies, and with high-resolution crystallography, which gives the detailed structural changes. (Without high-resolution crystallography the technique can still be used, but merely as a probe of the role of residues in catalysis, for instance.) A logistical difficulty that such combined methodology usually has to face is that the techniques of mutagenesis and kinetics are quick to yield results, but protein crystallography tends to lag behind. It is striking that this is not the case for the tyrosyl-transfer RNA synthetase studies, presumably in part because of growing familiarity with its structure.

The most noteworthy of a number of findings described by Fersht *et al.* is that a hydrogen bond involving a side chain with a net charge on it is stronger — by up to a factor of about six — than a hydrogen bond with no such involvement. Indeed by the time the difference in energy is properly weighted by a Boltzman exponential factor, a 'charged' hydrogen bond may well contribute one to two orders of magnitude more to specificity than an 'uncharged' one. That is useful to know in building up a database of interactions and it also reminds us of something that is often forgotten — hydrogen bonds are to a large extent simply a convenient way of looking at a part of the overall spectrum of electrostatic interactions between molecules or parts of molecules. A convenient way of expressing such an interaction is in terms of a multipole expansion

$$\frac{e_1e_2}{r_{12}} + \frac{e_1\mu_2 + e_2\mu_1}{r_{12}^2} + \frac{\mu_1\mu_2}{r_{12}^3} + \cdots\cdots$$

where e represents net charge and μ a dipole and 1, 2 refer to the interacting groups. The leading term in computing a hydrogen bond between neutral groups — like water molecules — is the third one. But if one group has a net charge, then the second term will lead and typically will be a good deal bigger. Since the problem is complicated by the presence of strongly dipolar water molecules, it would not have been very surprising had the effect of the charged hydrogen bond not shown up. That it has done, is well worth noting.□

Ecology

Competition in imaginary worlds

from Paul H. Harvey and Robert M. May

TO WHAT extent does competition influence the distribution of species among the islands of an archipelago? This seemingly straightforward question cannot easily be answered despite scores of studies using a variety of techniques to analyse the distributions of many plant and animal species from several groups of islands [1]. No consistent patterns emerge. Indeed, various authors working on the same data set often reach different conclusions because they have used different assumptions in their statistical models. A new approach by Colwell and Winkler [2],using a computer to generate a myriad of imaginary worlds, helps us to understand the limitations of conventional analyses for detecting the factors that actually govern the distribution of species in archipelagos.

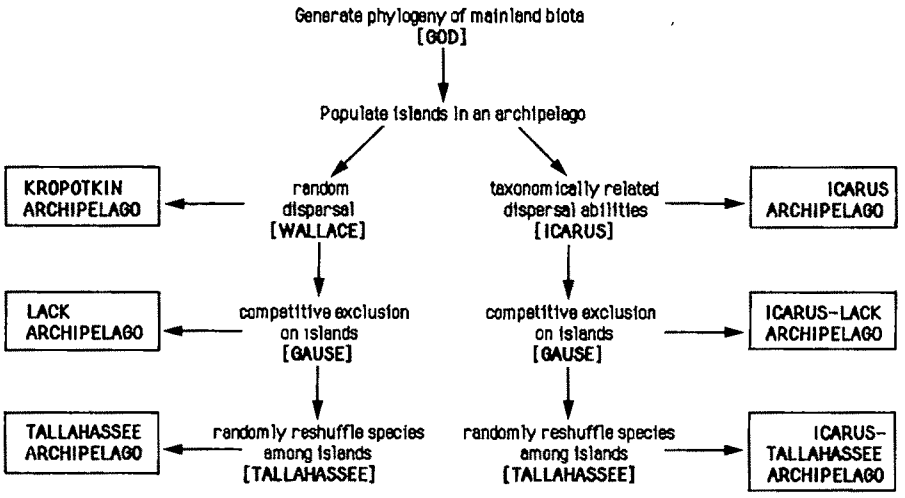
The essential problem is that each archipelago is unique, with its plant and animal species put in place by the slow workings of evolutionary processes. The logically appealing techniques of The Scientific Method — manipulative experiments with controls and replicates — are not easily applied in the real world. As emphasized by Simberloff, Strong and others at Florida State University [3], one way of trying to tease out the processes underlying observed patterns of distributions of species is to compare these patterns with null models constructed by randomly reshuffling the species among the islands. But the effects of competition may still inadvertantly be built into the null models, which assume that competition is absent

Colwell and Winkler[2] shed light on these problems by generating imaginary archipelagos, each populated according to specified rules. Using the worlds they have created, they explore the extent to which conventional methods of analysis can detect the competitive or other factors that actually govern the distribution of species in their archipelagos.

They begin by generating phylogenies, using a simple simulation model designed by Raup and Gould[4]. As the hypothetical species evolve, their phenotypes change gradually so that, on average, closely related species are more like each other than are more distantly related species. For the purposes of the model, easily measurable characters such as beak length and width are chosen. This evolution takes place on a large land mass under the guidance of a computer program called GOD. The organisms then disperse to the islands of a nearby archipelago, their destinations determined by additional computer routines, summarized in the figure.

One routine allows random invasion of the different islands with subsequent interspecific competition determining which species establish successful populations on each island. When phenotypically similar species invade an

island, some are likely to become locally extinct as a result of competitive exclusion. An alternative routine allows random invasion of islands from mainland without subsequent competition. As competition occurs only in the first routine, the second makes a suitable null model for comparison. One recent empirical study uses exactly this method: Graves and Gotelli [5] compare the actual avifaunas on land-bridge islands in the New World against the distribution patterns generated by sampling appropriate pools of mainland species.



But a different type of comparison is often made with real data. Species found on different islands are randomly redistributed among the same islands (by computer of course); the reassortment is then compared with the original distribution pattern [3]. Colwell and Winkler incorporate a computer routine that mimics this procedure. They find that the species distributions differ very little between the reassorted archipelago and the one on which competition has occurred, thus confirming that the effects of competition are indeed partly incorporated into the null model derived from the reassortment routine. Consequently a comparison that uses this procedure is less likely to detect the effects of competition than is Colwell and Winkler's first procedure [6,7].

Another factor, usually ignored, that leads to underestimating the influence of competition, is the varied abilities of different taxa to disperse [6,8]. For example, kingfishers are more vagile than kiwis, and so are likely to be found on islands which kiwis have not reached. In a second series of comparisons, Colwell and Winkler allow dispersal abilities as well as morphological characteristics to evolve in the phylogenies generated by their computer. The result is that closely related species tend to end up on the same islands. Some species are extirpated when competition occurs, thus producing a species assemblage on each island that is taxonomically less biased than that of the original invaders. Because differential dispersal abilities produce the opposite pattern from competition if they are ignored when designing null models, the effects of competetion are shown to be consistently underestimated.

Colwell and Winkler have also contributed to the comparisons of the distributions of species that are not likely to be in competition, the subject of several recent discussions[9-11]. Classic cases in the literature include searching for competitive exclusion between owls and hummingbirds or between ducks and warblers [12]. The simulation study helps to place this problem in context. Since the computer has a complete phylogenetic record, it can assign relative taxonomic status with accuracy. Comparisons made at lower taxonomic levels, say among species within a genus, are far more effective for detecting the statistical consequences of competition — the level at which the process acts most strongly — than those that incorporate a wider taxonomic spread, say an order or a class. Here, however, the creator (GOD, or Colwell and Winkler) has a considerable advantage in knowing the likely relations between competitive intensity and the phylogenetic relationship among species, whereas such relations may be less clear to an observer in the real world. Colwell and Winkler could, if they wished, give objective and usable criteria for assigning subsets of species into "guilds" containing species with similar patterns of resource utilization, whereas such decisions about grouping real species usually involve some subjectivity.

The problems do not stop here. Sample sizes tend to be small and Type II statistical error (failure to reject an incorrect null hypothesis) tends to be high, making it very difficult to reject the null model from which the effects of competition have been excluded [2]. Even if it can be, there are often alternative interpretations of the patterns revealed [5]. For example, habitats differ between islands and the complimentarity of species distributions could result simply from differences in habitat preferences or realized niches [5,13].

In the nature of things, ecologists and biogeographers can often obtain no more than circumstantial evidence. On the one hand, the studies of Colwell and Winkler illustrate some of the difficulties and pitfalls in working with such circumstantial evidence. On the other hand, by seeking to design appropriate null hypotheses that allow real patterns to be distinguished from statistical artefacts, they have achieved a constructive step in the direction indicated by Simberloff, Strong and colleagues [3]. Where manipulative field experiments are possible, the answers are usually much less ambiguous. Some experiments of this kind — for some taxonomic groups but not for others — point to the importance of competition in structuring natural communities [14,15]. □

Colwell and Winkler [2] generate a computer phylogeny using a routine called GOD, and distribute species among the islands of an archipelago according to rules specified by either WALLACE or ICARUS. The species on each island are then subjected to competition using GAUSE, to produce archipelagos with new species compositions. Finally the species on the post-competition archipelagos are redistributed among the islands using TALLAHASSEE. Recent analyses of real data sets search for the effects of competition by comparing the equivalent of the LACK and ICARUS-LACK ARCHIPELAGOS with the TALLAHASSEE and ICARUS-TALLAHASSEE ARCHIPELAGOS respectively. These comparisons consistently underestimate the effects of competition [2]. More suitable nulls models against which to compare the LACK and ICARUS-LACK ARCHIPELAGOES are the KROPOTKIN and ICARUS ARCHIPELAGOS respectively.

100 years ago

THE Prince of Wales, President of the International Inventions Exhibition, has fixed Monday May 4, for the opening of the Exhibition. Rapid progress is being made in all branches connected with the Exhibition. The large space set apart for machinery in motion is already being filled, whilst preparations for receiving other exhibits are well forward, some of which have arrived at the building. The Aquarium Department is receiving considerable attention, and will form a very attractive feature. Lord Onslow has lately presented 1500 exceedingly fine carp to the Aquarium, and a large number of fish indigenous to the Canadian Lakes have also been received for exhibition in the tanks.

From *Nature* **31** 465, 19 March 1885.

Mechanisms for homologous recombination

SIR — Fink and Petes [1] argued that the difference between a 50% frequency of crossing-over associated with meiotic gene conversion at homologous loci, on one hand, and absence of crossing-over associated with events involving repeated sequences at different locations in the genome on the other hand, suggested the existence of more than one pathway in homologous recombination. Fincham [2] and Whitehouse [3] stressed that the frequency of crossing-over associated with meiotic gene conversion varies widely and can be much smaller than 50%. They pointed out that eukaryote recombination can occur by a single pathway that entails two steps with gene conversion occurring in the first step and reciprocal exchange in the second: variation of crossing-over association might reflect special conditions required for the second step. Nevertheless, but for different reasons than Fink and Petes, we think that recombination events occurring at homologous positions in fungi may arise via several mechanisms.

Genetic analysis in fungi shows that gene conversion can occur via distinct pathways. It strongly suggests meiotic heteroduplex DNA intermediates, involving either one of the two interacting duplexes [4]. These intermediates can be matured by mismatch correction [5]. In yeast, gene conversion can occur by the repair of double-strand gaps [6] and it has been suggested that this might be a major pathway for meiotic recombination [7]. This diversity in the origin of gene conversion is illustrated by current models [7-9].

The competing models for gene conversion all retain the idea of a crossed strand junction at the end of the conversion area. They predict that crossing-over arises by the resolution of the junction and therefore is associated with gene conversion. These models cannot explain simply the evidence gathered over years of genetic analysis of the crossing-over mechanism. In particular we argue that reciprocal exchanges can be spatially and temporally separated from gene conversion. In *Sordaria* cross-overs can be separated from a site of gene conversion by a reigon in which a marker shows normal mendelian segregation [10]. In yeast, mitotic gene conversion events which occur in G_1 are sometimes associated with cross-overs in G_2 [11]. Unified models predict that frequency of gene conversion for a central marker should be high in cells which are recombinant for the flanking markers, when the interval between the outside markers is less than the average conversion length. However, in *Ascobolus*, reciprocal recombination selected within gene *b2* was found to be rarely associated with gene conversion in the interval [12].

Bacteriophage λ encodes functions for two recombination systems and is a substrate for host-encoded recombination. Why should eukaryotic genetic recombination involving much larger genomes be more simple? Eukaryotes should have evolved different recombinational systems to deal with the different situations in their genomes and life histories where recombination is required.

As an alternative to continual tinkering to explain unpalatable facts, it seems worth considering schemes which invoke multiple mechanisms for recombination. We believe that the recognition of this possibility may simplify models and rejuvenate research in the whole field of recombination.

Null hypotheses and prediction

SIR — In the past decade or so a subtle misuse of null hypotheses has become almost standard in ecology, biogeography, functional morphology and theoretical palaeontology. This comes from an overly strict adherence to the narrow Neyman-Pearson view of statistics as hypothesis-testing. The alternative approach of R.A. Fisher, himself an evolutionary biologist as well as the founder of modern statistics, emphasizes estimation, causation and the expansion of knowledge. (I simplify a complex subject.)

The difficulty here comes when a null hypothesis is placed in a privileged position, to be accepted at least provisionally until disproved. What we really want to know is how well it is supported compared with other possibiliites, not all of which may be precise or even known. For this one can compare likelihoods, calculate confidence intervals, and use similar, even qualitative, approaches which treat all possibilities as reasonable *a priori*.

It may be that, because of simplicity, theoretical coherence, prior knowledge, or the like, one possibility is indeed initially preferable, or the initial likelihoods of hypotheses may be unequal. Then one can merely incorporate such knowledge of via Bayes's theorem, precisely or very roughly, without the complexities of bayesian statistics. But it is rarely the case that one hypothesis is sufficiently preferable *a priori* that it should just be accepted until disproved.

For instance, the absence of adaptation for a particular structure should not be assumed until adaptation has been shown (itself often a difficult endeavour), although the possibility must be kept in mind. There are various mechanisms for nonadaptive and even inadaptive evolution at any one level [1,2], but most involve natural selection, and thus adaptation in some other way. Theoretical coherence based on a wide span of background knowledge actually gives a greater initial likelihood to direct or indirect adaptation without making, by itself, a precise and testable hypothesis.

Prediction is commonly associated with Popper, although it has been fashionable even in natural history since at least Cuvier's [3] time, and it is commonly regarded as the only way to do science. Yet much of the evolutionary half of biology, including the basic discovery by both Darwin and Wallace, is justified deductively [4], like mathematics. Within the domain where this is the case, hypotheses themselves are superfluous although prediction may be added, as Darwin did, to give additional justification.

We must not let the simplicity of a cookbook methodology blind us to real diversity. As Harvey *et al.* [5] recently quoted in another context, from Tukey [6], "Far better an approximate answer to the *right* question, which is often vague, than an exact answer to the *wrong* question, which can always be made precise."

The magnetic susceptibilities of a series of cluster carbonyl compounds of osmium have been measured by a high-sensitivity Faraday method and the evolution of certain aspects of 'metallic' behaviour in the high-nuclearity clusters is revealed by a steady increase in the excess molecular susceptibility as the cluster size increases. We also consider here 'metallic' status in the cluster compounds of other transition elements.

THE physical and chemical properties of small metallic particles with diameters < 100 Å (refs 1-6) are interesting because of their importance in heterogeneous catalysis and their position as intermediaries between the atomic and (bulk) metallic regimes. It is often asked in what manner, and at what nuclearity, atomic and molecular properties admit 'metallic' behaviour[1,6-13]. This description involves, to first order, the neglect of inter-cluster interactions and deals primarily with the evolution of the electronic structure of isolated cluster states. Representative examples include ultra-fine dispersed metal catalysts[2-4], 'naked' metal clusters formed via the controlled aggregation of metal atoms in low-temperature matrices[14-16], and, the subject of the present investigation, inorganic cluster compounds of the transition elements[17]. The study of small metallic particles poses severe experimental problems because of unavoidable distributions of particle size within a sample and the necessity for high-vacuum conditions to avoid contamination with oxide species[1]. In contrast, carbonyl cluster compounds of, for example, Os, Rh and Pt, of generic formula $M_m(CO)_n^{Q-}$, with $Q \geq 0$, $n > m$, are well characterized molecular species, obtainable in samples of very high purity, and many are air-stable. The cluster carbonyls of these three elements have been shown by X-ray crystallography to exhibit many different geometries (Fig. 1), which are fragments of extended metallic lattices (hexagonal close-packed (h.c.p.); face-centred cubic (f.c.c.); body-centred cubic (b.c.c.)), or resemble other types of close packing (for example, polytetrahedral, icosahedral), theoretically favourable for particles containing a few dozen atoms[17-20].

The compounds in Fig. 1 represent metallic cluster fragments isolated from adjacent cluster units by inert sheaths of carbonyl ligands; these cluster units are fundamentally different from, for example, those within the ternary molybdenum chalcogenides (ref. 21 and references therein), often called Chevrel phases, $M_xMo_6X_8$ (where M represents a rare earth or other metallic element and X is S, Se or Te), in which the chalcogen atoms occupy bridging positions between the metal cluster units, and extensive inter-cluster interactions give rise to itinerant electron behaviour at ambient temperatures, and superconductivity below ~15 K.

The transition-metal cluster carbonyls, therefore, may be ideal systems for monitoring the genesis of the electronic structure of particulate transition metals. We report here a systematic study of magnetism in the cluster carbonyls of osmium.

Magnetic measurements

The magnetic susceptibilities of the various Os cluster compounds were measured over the range 1.5-300 K using a high-sensitivity computer-interfaced Faraday balance, described elsewhere[22]. Samples were suspended on a 1-mm quartz rod from the arm of a Cahn RG electrobalance. The sample container (4.2 × 10 mm) was fashioned from high-purity Spectrosil quartz. An electromagnet (Eastern Scientific Instruments) supplied variable fields up to 11.8 kG. The magnetic field gradient was measured using $HgCo(SCN)_4$ as a standard and varied by < 2%. Temperature was controlled (±0.1 K) and monitored with a digital temperature controller (Oxford Instruments, DTC 2) using a Au/Fe versus chromel/P thermocouple. A calibrated silicon diode resistance thermometer was used to measure the sample temperature, independently of the controlling thermocouple, over the entire temperature range. The Cahn balance was operated on the 1-g scale, on which a sensitivity in ideal conditions of 0.0005 mg can be achieved; in normal operating conditions, the sensitivity was only ~0.001 mg and the reproducibility was ~0.001 mg. A typical error estimate in the measurement of magnetic susceptibility is $\pm 10 \times 10^{-6}$ e.m.u. mol^{-1} for $Os_3(CO)_{12}$ and $\pm 30 \times 10^{-6}$ e.m.u. mol^{-1} for the cluster $H_2Os_{10}C(CO)_{24}$. For each sample, magnetic measurements were taken at three values of the magnetic field, at 8.8, 10.5 and 11.8 kG. The total measured susceptibility values of the Os cluster compounds at room temperature, which are (overall) diamagnetic, range from $-170(\pm 10) \times 10^{-6}$ e.m.u. mol^{-1} for $Os_3(CO)_{12}$ to $-700(\pm 40) \times 10^{-6}$ e.m.u. mol^{-1} for $Os_{10}C(CO)_{24}I_2$ and have been corrected for the intrinsic magnetism of the sample container.

The experimental quantity of most direct interest is the excess molecular susceptibility, χ_{ems}, of the Os cluster compounds, which represents the difference between the magnetic susceptibility of the molecular complex (Fig. 1) and the sum of those species from which the complex is composed. The natural choice for these constituents is Os and H atoms, freely rotating CO molecules and, in the case of $H_2Os_{10}C(CO)_{24}$, an additional C atom (the interstitial C atom, Fig. 1). Reliable values for Os (-66×10^{-6} e.m.u. mol^{-1}), I (-52×10^{-6} e.m.u. mol^{-1}), C ($+5.0 \times 10^{-6}$ e.m.u. mol^{-1}) and H (-2.93×10^{-6} e.m.u. mol^{-1}) are given by König[23]. The measured magnetic susceptibility for gaseous CO is -9.8×10^{-6} e.m.u. mol^{-1}. The observed molar susceptibilities and derived excess molecular susceptibilities at 298 K and 11.8 kG for six cluster compounds of Os are given in Table 1 and these limiting high-temperature values are plotted as a function of cluster nuclearity in Fig. 2. Note that the

experimental excess molecular susceptibilities (χ_{ems}) are considerably larger than the intrinsic errors in our measurements. (For example, for the low-temperature susceptibility of $H_2Os_{10}C(CO)_{24}$ to arise from Os (IV) impurities, some 20% of the molecules in the sample would have to be Os(IV) complexes. No evidence of such complexes was found by infrared spectroscopy or X-ray diffraction.)

The magnetic susceptibilities of the entire series of Os clusters are truly temperature-independent down to 1.5 K, except for the decanuclear hydrido-cluster, $H_2Os_{10}C(CO)_{24}$, which shows a temperature-dependent paramagnetism at low temperature, approximating closely to a Curie-type behaviour.

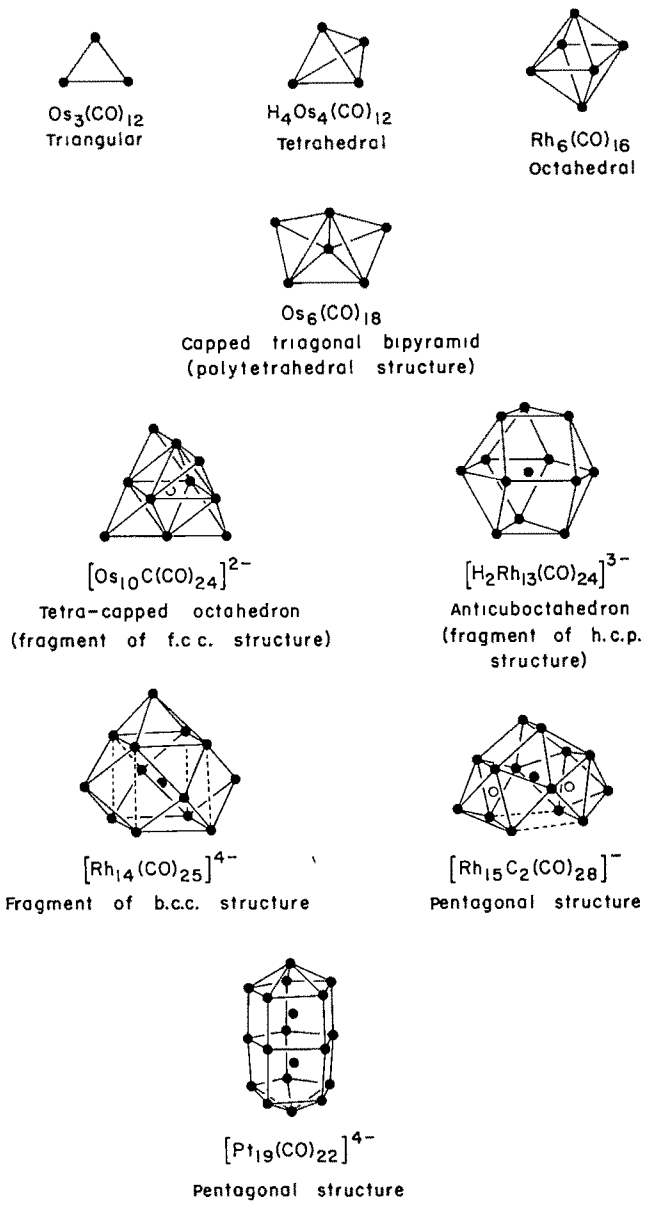

Fig. 1 A representation of typical metal atom geometries in transition metal carbonyls. For clarity, the carbonyl ligands have been omitted. Open circles denote interstitial carbon atoms in the cluster compound. **Materials.** The compounds $Os_3(CO)_{12}$, $H_2Os_3(CO)_{10}$, $H_4Os_4(CO)_{12}$, $Os_7(CO)_{21}$, $H_2Os_{10}C(CO)_{24}$ and $Os_{10}C(CO)_{24}I_2$ were prepared by existing methods[18,46]. The purity and composition of the samples were carefully checked by TLC, infrared spectroscopy and, in the case of the clusters containing <10 Os atoms, by mass spectrometry (AEI MS12, 100–150 °C). The elemental purity of all compounds was also tested by atomic absorption spectroscopy; the elements Mn, Fe, Co, Ni, Cu, Zn, Cd, Pb and Pd were tested in a 47-mg sample of the decanuclear cluster $H_2Os_{10}C(CO)_{24}$ and were undetectable down to the limits of detection of the absorption spectrometer, which were 1 p.p.m. for Fe and Zn, and 0.1 p.p.m for the remaining elements.

Discussion

The excess molecular susceptibilities (Fig. 2), χ_{ems}, are most naturally interpreted as arising from a Van Vleck paramagnetic contribution to the susceptibility. Somewhat related magnetic behaviour has been observed previously in transition metal (molecular) complexes that have nominal singlet ground states, for example, in $Cr_2O_7^{2-}$, MnO_4^- and WO_4^{2-} complexes, as well as in Co (III) complexes possessing a low-lying excited state[24–26]. However, of particular importance here is the marked increase in χ_{ems} with increasing cluster size (Fig. 2) and how this relates to our view of the electronic structure of these materials.

In the present instance, a Van Vleck contribution[26] to the observed susceptibility will arise from modification of the cluster wavefunction by the external magnetic field. The modified wavefunction is described by the admixture of excited states in which electrons are promoted from delocalized bonding orbitals of the cluster to the delocalized antibonding orbitals. As the second-order perturbation expression for this paramagnetic contribution contains terms inversely proportional to the excitation energies between the occupied and unoccupied molecular orbitals[26,27], the increase in χ_{ems} with increasing cluster size suggests that the excitation energy gap decreases correspondingly. This interpretation (discussed below) would be invalidated if the matrix element $\langle n|\mu_z|0\rangle$, connecting the ground state $|0\rangle$ with the excited state $|n\rangle$ of energy $(E_n - E_0)$ above the ground state, changed significantly with cluster size. This, however, is improbable.

That relativistic effects, of which spin-orbit coupling is the best known, may well be significant in a heavy atom such as Os does not invalidate our qualitative interpretation of χ_{ems}. Although a closed-shell ground state will contain admixtures of states having non-zero total-spin, S, in relativistic theory, such a closed relativistic configuration will still be symmetric under time-reversal; the operator describing the interaction of the closed shell with the external magnetic field is antisymmetric and thus, under this operation, the first-order energy of interaction vanishes. Hence, the observed magnetic contribution consists, apart from the usual diamagnetic term, of second-order effects in which the wavefunction is modified by the magnetic field. Note that attempts to account for the delocalization of cluster bonding electrons in molecular orbitals would lead to larger diamagnetic terms, as the electrons would necessarily have larger effective radii than those confined to single Os atoms; and the values of the excess molecular susceptibility would then be increased with respect to those given in Table 1.

Several limiting descriptions are applicable to this Van Vleck temperature-independent paramagnetism (TIP), sometimes called the 'high-frequency' or 'second-order Zeeman' paramagnetism (see ref. 27 for a detailed review of the four important situations). Note that the same energy denominator that governs the magnitude of the Van Vleck paramagnetism is also responsible for the important paramagnetic contribution to the chemical shielding constant in nuclear magnetic resonance (NMR)[28]. However, one of the matrix elements in the NMR situation differs slightly from that in the Van Vleck paramagnetism.

In the normal case where the characteristic energy gap $(E_n - E_0)$, separating occupied from vacant orbitals, is large compared with the thermal energy, that is, $(E_n - E_0) \gg kT$, the induced paramagnetism is truly temperature independent[27,29]. The Os clusters would, at first sight, be expected to have a pure spin-singlet magnetic ground state. Thus, theories of bonding have successfully concentrated on the number of skeletal electron pairs required to bind the metal cluster unit, implicitly assuming a pure diamagnetic ground state[30,31]. The magnetic behaviour (Fig. 2) suggests that this picture is reasonable for small clusters, but becomes inappropriate for larger clusters in which there is obviously a large reduction in the frontier-orbital energy gap. Overall, then, we attribute the increasing Van Vleck TIP contribution for the high-nuclearity clusters primarily to a reduction in $E_n - E_0$, identified here as a measure of the separation of the frontier orbitals in the cluster[32]. A theoretical molecular

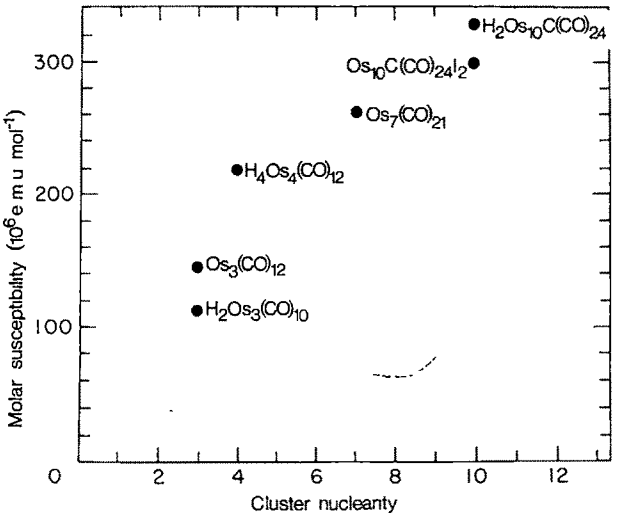

Fig. 2 Magnetism in Os cluster carbonyls. The variation of the high-temperature (298 K) excess molecular susceptibility, χ_{ems}, as a function of cluster nuclearity.

orbital study has been made[33] on $Ru_3(CO)_{12}$, isostructural with $Os_3(CO)_{12}$, to aid interpretation of its ultraviolet/visible electronic spectrum[34]. The first excited state in this D_{3h} molecule lies ~3 eV (24,000 cm^{-1}) above the ground state. Although optical transitions to this particular state are forbidden, it is of the correct symmetry to give a non-zero value for $|\langle n|\mu_z|0\rangle|^2$. This leads to a value for the TIP susceptibility of $\sim 180 \times 10^{-6}$ e.m.u. mol^{-1}, if we estimate $|\langle n|\mu_z|0\rangle|^2$ from symmetry arguments[35], which is indeed consistent with our observed value for $Os_3(CO)_{12}$. The next three excited states correspond to allowed optical transitions, but are magnetically forbidden, so that the sum over excited states in the calculation of the excess molecular paramagnetism is dominated by the HOMO–LUMO interaction, in this case.

It is important to note that these cluster molecules are tightly bound and contain electronic energy levels with values of $(E_n - E_0)$ greatly different from those of the individual interacting metal centres[36]. If the cluster units were loosely bound, as in the case of van der Waals-type clusters of noble gas atoms[19,37], their magnetic properties would simply be those of an assembly of mononuclear metal carbonyl fragments. This is clearly not the case for the title systems.

The ultraviolet/visible spectra of larger clusters show a trend towards absorption at lower frequencies. Chini[32] has noted that this trend can be taken to reflect the separation of frontier orbitals, which clearly correlates with the colour sequences found in the Os clusters and carbonylmetallates. If excited states of suitable symmetry are present, this would give rise to an increased TIP susceptibility as the cluster size increases (Fig. 2). Unfortunately, a more detailed discussion would be premature, as our knowledge of the excited electronic states in cluster molecules is extremely limited[20]. Very few data are available for the electronic absorption spectra of high-nuclearity clusters. Satisfactory quantitative theoretical calculations on large many-electron clusters of metal atoms with large spin-orbit coupling constants cannot at present be performed. Even the relatively simple case of the dichromium molecule, Cr_2, has given rise to considerable disagreement among the results from different methods of calculation[38]. Extended Hückel molecular-orbital calculations using Rh atom parameters have been partially successful, but an incorrect number of cluster valence molecular orbitals was obtained[39] for (ligand-free) 10-atom clusters having the geometry of $H_2Os_{10}C(CO)_{24}$.

If one traces the evolution of the Van Vleck paramagnetic contribution from the situation when $(E_n - E_0) \gg kT$, to $(E_n - E_0) \ll kT$, then the second-order Zeeman effect transforms smoothly from temperature-independent paramagnetism, to a Curie-type paramagnetism[7,29]. For the situation in which the characteristic energy gap is sufficiently small to be comparable with kT, namely, $(E_n - E_0) \leqslant kT$, the resulting contribution to the magnetization gives a susceptibility contribution proportional to $<n|\mu_z|0\rangle|^2/kT$. This has the usual Curie form, although here the mechanism of magnetization is by the admixture of virtual excited states into the ground state, whereas for 'free' (Curie) spins, the mechanism is that of redistribution among the spin states[29]. Note that, in this case, the energy parameter $(E_n - E_0)$ does not enter into the paramagnetic contribution. In the intermediate regime, Figgis[27] has noted that the observed magnetic susceptibility contains contributions from both types of effect.

Table 1 Magnetic susceptibility data for Os clusters (298 K)*

Cluster	χ_m(obs) (10^6 e.m.u. mol^{-1})	χ_{ems} (10^6 e.m.u. mol^{-1})
$Os_3(CO)_{12}$	−170 ± 10	+146 ± 10
$H_2Os_3(CO)_{10}$	−188 ± 10	+114 ± 10
$H_4Os_4(CO)_{12}$	−200 ± 10	+219 ± 10
$Os_7(CO)_{21}$	−405 ± 20	+263 ± 20
$H_2Os_{10}C(CO)_{24}$	−580 ± 30†	+326 ± 30
$Os_{10}C(CO)_{24}I_2$	−700 ± 40	+304 ± 40

* All values are corrected for the susceptibility of the Spectrosil container. The experimental data are temperature-independent down to 1.5 K; except for $H_2Os_{10}C(CO)_{24}$†, which is temperature-dependent below ~150 K.

We have reported[40] that the decanuclear cluster $H_2Os_{10}C(CO)_{24}$ behaves in this fashion, revealing a strong temperature-dependent paramagnetism at low temperatures. In addition, preliminary magnetic measurements on several high-purity anionic decanuclear Os clusters also show a Curie-type paramagnetism in the magnetic susceptibility. In terms of the Van Vleck theory of magnetism, this strong paramagnetic susceptibility is nominally symptomatic of a diamagnetic state in which the energy gap separating the ground state and excited state for mixing is comparable with kT. However, we caution against accepting this statement as a rigorous characterization of $(E_n - E_0)$ from the susceptibility data, as the thermodynamic and magnetic properties depend on the overall pattern of energy levels[41–43]. In particular, it is not clear whether the assumption of Boltzmann-type statistics is indeed valid for a metal cluster of this size, that is, whether Fermi–Dirac statistics would not be more appropriate in this particulate metal regime.

An alternative description, much discussed in solid-state physics[1,11,12], approaches the problem from the bulk metallic regime and considers the consequences of the fragmentation of a metallic sample into a 'particulate' metal. Briefly, the finite extension of the electron wavefunction within a particulate metal causes a changeover of the electron levels from quasi-continuous to discrete. The results of theoretical calculations of the magnetic properties of particulate metals depend on the assumptions made concerning the overall distribution of energy levels, for example, whether they are equally spaced, or in a Poisson distribution, and whether or not degeneracy of levels is allowed[41,42]. The unitary ensemble calculation, most appropriate for metals (such as Os) with high spin-orbit coupling, is the least studied, but a transition from the temperature-independent Pauli paramagnetism of bulk metals to a Curie-type behaviour in the magnetic susceptibility has been predicted for both odd- and even-electron metals[12,41,42]. Experimental observations of enhanced low-temperature susceptibility have been made for particles of metals as diverse as lithium[44] (odd electron), magnesium[45] and platinum[42] (even electron).

In terms of its magnetic properties, the decanuclear cluster $H_2Os_{10}C(CO)_{24}$ may be representative of a small metallic particle in the so-called quantum-size effect regime.

We note that the structure of $Os_{10}C(CO)_{24}I_2$ is considerably more 'open' than the hydrido-cluster $H_2Os_{10}C(CO)_{24}$, because of the bonding contribution of the iodine atoms[46]. It may be more correct in this context to regard the iodo-cluster as an octanuclear cluster with two extra peripheral (edge bridging)

Os atoms. In $Os_{10}C(CO)_{24}I_2$, only temperature-independent paramagnetism is observed (Fig. 2).

The low-temperature paramagnetism of $H_2Os_{10}C(CO)_{24}$ has been further investigated by electron paramagnetic resonance (EPR). Spectra of polycrystalline $H_2Os_{10}C(CO)_{24}$ showed a broad almost-symmetrical lorentzian resonance centred at $g = 2.27 \pm 0.02$. As the temperature was raised, the peak-to-peak linewidth, ΔH_{pp}, increased from ~50 G at 18 K to ~80 G at 77 K.

EPR signals with characteristic dysonian (asymmetrical) lineshapes are given by conduction electrons in bulk metals[48]. The mechanism of electron spin relaxation in metals has been discussed in detail by Elliott[49,50], who showed that spin relaxation occurs through the combined agencies of electron–phonon scattering and spin–orbit coupling. For heavy bulk metals in which spin–orbit interactions are large, for example, Os with a spin–orbit coupling constant of ~1,000 cm^{-1}, electron spin relaxation times are expected to be extremely short and EPR resonances are anticipated to be broadened beyond detection at ambient temperatures[51]. Using values of the resistivity relaxation rate (τ_R^{-1}), derived from measurements on bulk Os metal, and taking $g = 2.27$, gives an electron spin lattice relaxation rate of $2 \times 10^{14}\ s^{-1}$; the corresponding EPR linewidth would be $\sim 1 \times 10^7$ G, clearly undetectable. But a relaxation rate of $\sim 1 \times 10^9\ s^{-1}$ is indicated from the EPR of $H_2Os_{10}C(CO)_{24}$.

This large reduction in electron spin relaxation rate from the bulk Os value is also consistent with a description of $H_2Os_{10}C(CO)_{24}$ as a particulate metal. It is well established that electron spin relaxation processes are inhibited or suppressed in this quantum-size effect regime[12,52]. Briefly, in a particulate metal the electronic energy level spacing may become comparable with the magnetic Zeeman energy. Quenching of the electron spin relaxation processes in small metallic particles arises because electron (spin) transitions between these discrete energy levels[52] are restricted as opposed to the situation in a bulk metallic sample[49]. Therefore, this quantum-size effect considerably narrows the EPR absorption and it may become detectable. Moreover, if the particle diameter is smaller than the characteristic microwave skin depth, the lineshape changes from dysonian to lorentzian[48,50]. EPR signals of lorentzian shape have indeed been observed for small particles of metals with both odd (for example, alkalis[50], silver[53–55]) and even (for example, magnesium[44] and platinum[56]) numbers of valence electrons. Similarly, small metallic particles studied[57] by EPR in alkali halide (host) crystals include the (even electron) 2nd row transition metals Pd and Cd. There have been no reports of Os colloids isolated in these host materials.

Conclusions

This study of the magnetic properties of a series of Os clusters demonstrates experimentally the manner in which the changeover from molecular to 'particulate-metal' behaviour may develop as a cluster aggregate forms. The temperature-independent Van Vleck paramagnetism increases sequentially with cluster size as the molecular electronic states begin to develop into the band or continuum regime and ultimately terminates in the characteristic Pauli paramagnetism in the bulk metallic state. Moreover, electronic states within the particulate-metal regime, in which quantum-size effects may be operative, can exhibit enhanced paramagnetism compared with both their localized- and itinerant-electron counterparts. Similar observations have been made on particulate samples of several metals. There are other theoretical predictions and experimental observations of enhanced paramagnetism in this 'narrow-band' regime separating the metallic and insulating states[58,59].

We have demonstrated the considerable sensitivity of magnetic measurements in detecting the onset of certain aspects of what may be termed 'metallic' behaviour. This has an important bearing on the question[6], 'how many atoms are needed in an aggregate or cluster to mimic effectively the bulk properties of a metal'? The answer must obviously depend on which particular property of the metal one wishes to describe. Transport properties (for example, conductivity, Hall effect) require, as a prerequisite for detection of metallic character, the complete ionization of an electron from its parent site, which typically involves energy changes in the range 10^{-1}–10 eV. As far as the magnetic properties are concerned, modifications to the intra- and inter-unit exchange energy in the metal cluster as the nuclearity increases need only be of the order of magnitude of the magnetic Zeeman or hyperfine energies (both typically in the range 10^{-4} eV) for noticeable changes to be observed. These types of experimental considerations are fundamental to any consideration of 'metallic' characteristics. Several authors[1,7–10,60] have suggested a criterion for bulk properties in clusters based on the width of the electron d band, as determined experimentally, for example, by photoelectron spectroscopy. Such a criterion obviously involves large energy terms in the range 1–10 eV. Similarly, quantum mechanical calculations aimed at reproducing bulk-metal d-band widths in clusters seem certain to require several hundreds, or even thousands, of atoms before metallic status would be conferred on the aggregate[7–10]. These approaches may overlook and obscure many interesting magnetic and optical properties of clusters in the particulate-metal regime.

We have suggested that transition metal carbonyl cluster compounds represent ideal model systems for monitoring the genesis of a particulate metal from individual molecular units. Transition metal cluster compounds of slightly higher nuclearity than those examined here may show very interesting electronic properties, possibly arising from a polarization catastrophe[6] within the cluster units themselves.

This research was funded by the SERC and NSF; travel grants enabling the Cornell/Cambridge collaboration were supplied by NATO (grant 250.81) and the Royal Society. We thank Professor Sir Jack Lewis, Dr B. F. G. Johnson and Professor A. D. Buckingham for their support during all stages of this investigation. We also thank Dr N. C. Pyper for his reading of the manuscript and for many helpful suggestions.

The role of complementary hydrogen bonding as a determinant of biological specificity has been examined by protein engineering of the tyrosyl-tRNA synthetase. Deletion of a side chain between enzyme and substrate to leave an unpaired, uncharged hydrogen-bond donor or acceptor weakens binding energy by only 0.5–1.5 kcal mol^{-1}. But the presence of an unpaired and charged donor or acceptor weakens binding by a further ~3 kcal mol^{-1}.

THE hydrogen bond is a ubiquitous feature of biological interactions: it is essential in determining the structure of proteins and nucleic acids; it is a major determinant of specificity in enzyme catalysis and in biological information transfer; and it can influence directly the rate of enzymatic reactions by stabilizing the ionic charges formed in the transition state. Hydrogen bonding in macromolecules and their complexes in aqueous solution is a complex phenomenon because water competes for the hydrogen-bonding sites[1,2]. The calculation of the overall energetics is consequently difficult and there is little knowledge of the energies involved[3]. Here we apply an experimental approach to the problem, using site-directed mutagenesis to produce mutant enzymes that differ in their abilities to form hydrogen bonds with their substrates. The interaction energies can be calculated from kinetic data on the modified enzymes.

Our experimental system is the tyrosyl-transfer RNA synthetase from *Bacillus stearothermophilus*. This enzyme catalyses the aminoacylation of $tRNA^{Tyr}$ in a two-step reaction; activation of the amino acid to form the enzyme-bound tyrosyl adenylate complex followed by transfer to $tRNA^{Tyr}$ (ref. 4).

$$E + Tyr + ATP = E.Tyr\text{-}AMP + PP_i \quad (1)$$

$$E\ Tyr\text{-}AMP + tRNA = Tyr\text{-}tRNA + AMP \quad (2)$$

The particular suitability of this enzyme (E) for obtaining accurate kinetic data and its other favourable characteristics for systematic site-directed mutagenesis have been described in detail elsewhere[5]. The three-dimensional structure of the enzyme and its bound aminoacyl adenylate are known from X-ray crystallography[6–9]. Eleven possible hydrogen bonds have been identified that may be formed between the enzyme and substrate, eight of which are from amino-acid side chains that may be mutated (Fig 1). We are systematically mutating these residues to measure the energetics of their interactions and to test whether hydrogen bonds are actually involved[10]. In all cases, the mutations lead to a smaller side chain that either lacks or has a modified hydrogen-bond donor or acceptor. Our initial data are consistent with hydrogen bonding being an exchange reaction whereby the hydrogen-bond donors and acceptors on the free enzyme and free substrate break their bonds with water on forming the bonds in the enzyme-substrate complex[5,11,12]. Here we analyse the effects of mutation of several different types of hydrogen bonds, including bonds from residues involved in determining the high specificity of the enzyme for tyrosine rather than phenylalanine (Tyr 34), bonds for simple binding of the substrate (Cys 35, His 48, Thr 51, Tyr 169) and a bond closer to the seat of reaction (Gln 195). These bonds may be classified further according to charge; most are between uncharged polar residues, but some involve a charged group on either the enzyme or substrate.

Experimental observations

Our experimental results for the activation of tyrosine are listed in Table 1. The contributions of the side chains to binding were calculated from the values of k_{cat}/K_M as described previously (ref. 5, Table 2). Note that the data refer to the binding of the substrate in the transition state. Such data give, in general, the most reliable measurements of incremental binding energies as the effects of strain, nonproductive binding and induced fit do not affect k_{cat}/K_M (ref. 13). The data for the activation of phenylalanine by the wild-type enzyme and a mutant in the specificity pocket are listed in Table 3. The contributions of side chains to binding energy, discussed in more detail below, may be summarized and classified thus: (1) deletion of a side chain on the enzyme that forms a good hydrogen bond with an uncharged group on the substrate weakens binding energy by only 0.5–1.5 kcal mol^{-1}; (2) deletion of an uncharged side chain on the enzyme that forms a hydrogen bond with a charged group on the substrate weakens binding by ~3.5–4.5 kcal mol^{-1}—only two relevant experiments were performed for this category and so the range could be much wider, but the crucial point is that these energies are considerably higher than in (1); (3) deletion of a group that forms a too-long hydrogen bond actually improves binding.

Effects of removal of side chains

Our measurements on the mutated enzymes give the overall contributions of the side chains to binding. The hydrogen bond donors/acceptors that are removed on mutagenesis are the only portions of the side chains in direct contact with the substrate. But the mutation of an amino acid in a protein from a larger side chain to a smaller may have further structural consequences superimposed on the energetics of the hydrogen bonding. Any fine structure analysis must consider these possibilities and

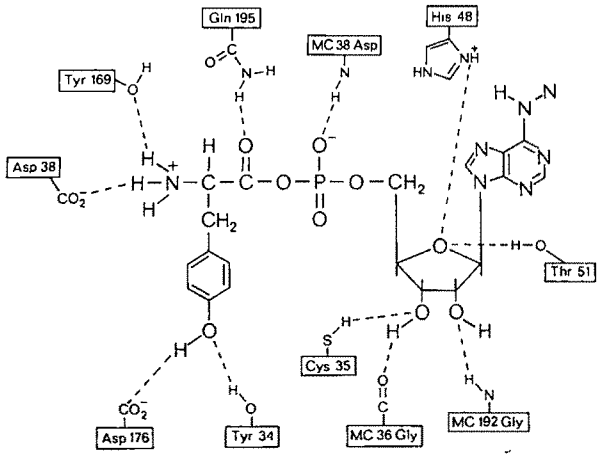

Fig. 1 Hydrogen bonds between the tyrosyl-RNA synthetase and tyrosyl adenylate. MC, main chain.

attempt to eliminate artefacts. The obvious experimental procedure is to crystallize the mutants and use protein crystallography to detect structural changes. Such a technique will detect changes of ~0.1 Å or more but will miss a series of smaller changes. (The effects of small relaxations of protein structure on binding are not known.)

Because kinetics measurements are exceptionally sensitive and can detect changes of a fraction of a kilocalorie, we use kinetic methods to increase the reliability of analysis. For example, application of the 'double-mutant' procedure of Carter *et al.*[14] has shown that mutation of residues 35 and 48 does not cause structural changes propagated through the protein[14]. Experiments in which we have mutated side chains by the removal of methyl groups buried in the protein, however, show that these small changes can weaken binding by up to 1 kcal mol^{-1} (A.J.W., A.R.F., P.C. and G.W., unpublished data). Because of this, we have analysed many different mutants to observe trends. The combination of the extensive and consistent kinetic data (see below) and modelling by molecular graphics suggests that the results so far reflect the direct effects of hydrogen bonding itself and are not dominated by structural change.

Hydrogen-bond strengths *in vacuo*

The stabilization energies of hydrogen bonds *in vacuo*, between compounds X-H and B-Y in equation (3), have been calculated[15]:

$$\text{X-H}\cdots\text{B-Y} = \text{X-H} + \text{B-Y} \qquad (3)$$

(where −H is a hydrogen-bond donor and −B is an acceptor). Representative values for the energies of stabilization for different donors and acceptors are: water/water, −6.4 kcal mol^{-1}; water/CH_3SH, −3.1 kcal mol^{-1} for −SH as the acceptor, −3.2 kcal mol^{-1} for −SH as the donor; imidazolium/water, −14 kcal mol^{-1}; acetate/water, −19.8 kcal mol^{-1}. These values are much greater than those in Table 2 for the overall energies of bonding in aqueous solution.

General model for H bonding in water

Our data fit the formulation of Jencks[16] and Hine[17]:

$$\text{E-H}\cdots\text{OH}_2 + \text{HOH}\cdots\text{B-S} = \text{E-H}\cdots\text{B-S} + \text{HOH}\cdots\text{OH}_2 \qquad (4)$$

For convenience, we assume that the enzyme has a hydrogen-bond donor, −H, and the substrate (S) an acceptor, −B, that pair in the enzyme-substrate complex. In the free enzyme, −H and −B are bound to water molecules. The number and types of hydrogen bonds are conserved in the reaction, which is thus essentially isoenthalpic (within the limits of Hine's[17] equation). For example, as discussed by Wilkinson *et al.*[5], a −SH group is just as effective as a −OH group as a hydrogen-bond donor/acceptor, despite the different absolute strengths of −SH···O and −OH···O bonds in equation (3); if, in equation (4), −H is part of a −SH group, then there is a −SH···O bond

Table 1 Activation of tyrosine by tyrosyl-tRNA synthetase and its mutants

Enzyme	k_{cat} (s^{-1})	K_M (ATP) (mM)	K_M (Tyr) (μM)	k_{cat}/K_M (ATP) ($s^{-1}\,M^{-1}$)	k_{cat}/K_M (Tyr) ($s^{-1}\,M^{-1}$)
Wild type	8.35	1.08	2 23	7,730	3.74×10^6

Δ(321-419)†	7.50	1.08	2.4	6,940	3.12×10^6

Mutant enzymes were prepared, assayed and active-site titrated as described previously[5,14]. Activation was measured by pyrophosphate exchange at 25 °C, *p*H 7.78 in the presence of 144 mM Tris-Cl, 10 mM $MgCl_2$ and 2 mM PP_i. Kinetic constants for variation of ATP were determined in the presence of 0.05 mM tyrosine (except where indicated otherwise) and for tyrosine in the presence of 2 mM ATP. Values of k_{cat} are extrapolated to infinite concentration of tyrosine and ATP.

* 0.3 mM tyrosine.

† Experiments on truncated enzyme with residues 321–419 deleted (the tRNA binding domain)[22].

‡ 1.7 mM tyrosine.

on the left-hand side and a −SH···O bond on the right in the enzyme-substrate complex. The contribution of hydrogen bonds to enzyme-substrate binding energy arises from entropy; water hydrogen bonded to the enzyme or substrate has lower entropy than bulk water and the release of hydrogen-bonded water helps drive enzyme-substrate binding[13,16]. Thus, there is a crucial distinction between the absolute energy of a hydrogen bond as in equation (3) and the overall energetics of hydrogen bonding in solution. It is the overall energetics that are important in the binding of enzymes and substrates, and it is the overall energetics that we measure from site-directed mutagenesis.

The removal of one of the hydrogen-bonding groups from equation (4), for example a side chain of the enzyme as in equation (5),

$$\text{E}\,\text{OH}_2 + \text{HOH}\cdots\text{B-S} = [\text{E B-S}] + \text{HOH} + \text{OH}_{2(\text{bulk})} \qquad (5)$$

does not necessarily lead to the loss of the absolute binding energy (enthalpy) of a hydrogen bond as defined by equation (3). Deletion of a hydrophilic side chain means that a water molecule must be located next to a hydrophobic region of the enzyme in the space vacated. This water molecule is at a high energy because it is at an interface and not in bulk water where it can fulfil readily all its hydrogen bonding. There is no hydrogen bond from E to H_2O in the free enzyme and so this partly (or even fully) compensates for the lack of the hydrogen bond from E to −B in the enzyme-substrate complex. When the substrate binds, it displaces the high-energy water molecule (which returns to the bulk solvent), and the hydrophilic hydrogen-bond acceptor of the substrate occupies the 'hydrophobic' site. The overall energetics of the reaction in equation (5) depend on the precise interactions made by the mutant enzyme with the water molecule and the group −B on the substrate. If, for example, the enzyme-bound water molecule in equation (5) is in the same orientation as that in equation (4), then equation (5) may be written as

$$\text{E}\,\text{OH}_2 + \text{HOH}\cdots\text{B-S} = [\text{E B-S}] + \text{HOH}\cdots\text{OH}_2 \qquad (6)$$

There is one hydrogen bond on the right and a similar one on the left of equation (6). This reaction is approximately isoenthalpic when −B is −OH and, to a first approximation, the energetics of equation (6) are the same as those of equation (4). Therefore, deletion of the hydrogen bond in the enzyme-substrate complex does not lead to the overall loss of the absolute strength of a hydrogen bond and may, in certain circumstances, cause no loss of binding energy. The energetics clearly depend on the precise nature of the interactions in each particular example and so will

Table 2 Comparative binding energies of wild-type and mutant enzymes with substrates

Comparison (Residue and position)		Substrate	ΔG (kcal mol^{-1})
Phe 34	Tyr 34*	Tyr	0.52
Gly 35	Cys 35*	ATP	1.14
Ala 51	Cys 51	ATP	0.47
Gly 48	Asn 48	ATP	0.77
Gly 48	His 48*	ATP	0.96
Ser 35	Cys 35*	ATP	1.18
Phe 169†	Tyr 169*†	Tyr	3.72
Gly 195	Gln 195*	Tyr	4.49
Gly 35	Ser 35	ATP	−0.04
Ala 51	Thr 51*	ATP	−0.44

The first two columns show the residues compared. The apparent contributions (ΔG) of the side chains of different amino acids to the binding energy of the enzyme–transition state complexes were calculated by comparing the ratios of k_{cat}/K_M for activation by wild-type and mutant enzymes as described previously[5], using the equation $\Delta G = -RT \ln\{(k_{cat}/K_M)_{mut}/(k_{cat}/K_M)_{wt}\}$ (subscripts mut and wt refer to mutant and wild-type (or reference) enzymes respectively).

* Wild-type; † truncated enzyme[22].

Table 3 Activation of tyrosine and phenylalanine by tyrosyl-tRNA synthetases

Enzyme	Activation of Tyr			Activation of Phe	$\frac{(k_{cat}/K_M)_{Tyr}}{(k_{cat}/K_M)_{Phe}}$
	k_{cat} (s^{-1})	K_M (μM)	k_{cat}/K_M ($s^{-1}M^{-1}$)	k_{cat}/K_M ($s^{-1}M^{-1}$)	(Relative specificity)
Wild type	5.4	2.2	2.5×10^6	17	1.5×10^5
Tyr→Phe 34	4.4	4.4	1.0×10^6	100	1.0×10^4

Impurities of tyrosine in the phenylalanine were removed by scavenging with tetranitromethane[23]. Conditions as described in Table 1 but data are not extrapolated to infinite concentration of ATP but given for 2 mM ATP. For activation of phenylalanine, the Phe concentration was varied between 5 and 30 mM, well below the K_M value. The specificity of wild-type enzyme is close to that measured previously under different conditions[23].

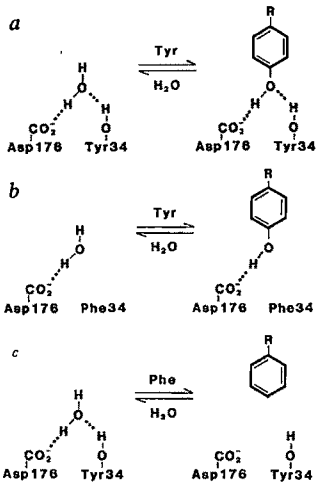

Fig. 2 Illustration of the hydrogen-bond inventory on tyrosine and phenylalanine binding to the tyrosyl-tRNA synthetase. *a*, Binding of wild-type enzyme and tyrosine involves the formation of two hydrogen bonds between its hydroxyl and Asp 176 and Tyr 34, but two equivalent hydrogen bonds of Asp 176 and Tyr 34 with water are broken. *b*, Binding of tyrosine to the Tyr→Phe 34 mutant involves just the formation of one hydrogen bond with the enzyme, but only one hydrogen bond is broken on displacing the bound water molecule. *c*, The binding of phenylalanine to the enzyme with the concomitant displacement of water would lose a strong hydrogen bond between water and Asp 176 and lead to a partially desolvated charge between the enzyme and substrate. Also, Tyr 34 would be unsolvated. Further, when tyrosine is bound, there are van der Waals' interactions between its phenolic hydroxyl and the enzyme, which are not present when phenylalanine is bound. It is probable that phenylalanine binds to the enzyme with the water molecule remaining bound between Asp 176 and Tyr 34. Note that in *a* and *b* the water molecules released from the enzyme on the binding of tyrosine can be considered to take the place of the tyrosine hydroxyl in solution so that there is no net change in the number of hydrogen bonds in solution.

vary from case to case. Before this study, the magnitudes of the energetic changes were unknown. Now we discuss these and show how particular examples may be rationalized and categorized.

Case A. Deletion of a side chain (−H) that interacts with an uncharged group on the substrate. Equation (5) or (6) describes this. The low contribution to specificity of a hydrogen bond between two uncharged residues is exemplified by the mutation Tyr→Phe 34 (Figs 1, 2). This is a very conservative mutation whereby a small group is deleted whose interaction is important in the recognition of tyrosine compared with phenylalanine. Yet, K_M for tyrosine increases by a factor of only two (Table 1) and the specificity for tyrosine decreases by a factor of only 15 (Table 3). The apparent bond energy of 0.5 kcal mol^{-1} is one of the lowest yet found, perhaps because the tyrosine −OH is a poorer hydrogen-bond acceptor than an aliphatic or water −OH and so the bond from Tyr 34 to the tyrosyl −OH of the substrate is relatively weak. The thiol-containing side chain from Cys 35, which donates to the 3′-OH of the ribose of ATP, contributes 1.1 kcal mol^{-1}. The tyrosyl-tRNA synthetase from *Bacillus caldotenax* differs from the enzyme from *B. stearothermophilus* by only four amino-acid replacements (M.D. Jones, unpublished data). One of these is an asparagine at position 48. The side chain of Asn 48 contributes 0.77 kcal mol^{-1} and that of His 48 contributes slightly more binding energy at 0.96 kcal mol^{-1}.

Note that equation (5) is relatively insensitive to the nature of the side chain deleted (when −B is uncharged). For example, consider the deletion of a charged histidine side chain (−H is imidazolium) as in the mutation His→Gly 48. Then, relative to wild-type enzyme, a strong interaction between imidazolium and the substrate is lost in the mutant enzyme–substrate complex, but this is compensated for by a loss of a strong interaction between imidazolium and water in the free mutant enzyme.

We have analysed several mutants as well as those listed in Table 2. In all cases, the deletion of a side chain that interacts with an uncharged group on the substrate loses between 0.5 and 1.5 kcal mol^{-1} of binding energy.

Case B. Deletion of a side chain that interacts with a charged group on the substrate. This is exemplified by the mutation Tyr→Phe 169 (Fig. 1) whereby the hydrogen bond to the ammonium ion is lost in the enzyme–substrate complex. Equation (5) still describes the situation, but there is now the loss of a strong hydrogen bond between the charged group on the substrate and water when forming the enzyme–substrate complex and 3.7 kcal mol^{-1} of binding energy are lost on Tyr→Phe 169. Gln 195 binds to a carboxylate oxygen of tyrosine in the E.Tyr complex and to the carbonyl oxygen of tyrosyl adenylate (Fig. 1; refs 6, 7, 18). On mutation of Gln→Gly 195 there is a loss of binding energy of 4.5 kcal mol^{-1} in the transition state where the oxygen atom is fractionally charged.

Case C. Deletion of a group on the substrate that interacts with a charged residue on the enzyme, described by the equation.

$$E\text{-}H^+\cdots OH_2 + HOH\,S = [E\text{-}H^+\,S] + HOH + OH_{2(bulk)} \quad (7)$$

This has similar consequences to Case B. A strong interaction in the enzyme–water complex is lost, an example being the 'modification' of tyrosine to phenylalanine. Phenylalanine binds more poorly to the enzyme by ~7 kcal mol^{-1} (Table 3). The phenylalanine either displaces the water molecule that is bound between Asp 176 and Tyr 34 in the enzyme (Fig. 2), leaving two unpaired hydrogen bonds, or, more probably, binds with a water molecule still bound between Asp 176 and Tyr 34. The water is crammed in a space which is too small, so that there are unfavourable interactions with the substrate.

A minimum estimate of the strength of the bond between Asp 176 and the tyrosine −OH can be made from the relative binding of tyrosine and phenylalanine to the mutant Tyr→Phe 34 (5.45 kcal mol^{-1} calculated from the data in Table 3). If phenylalanine displaces the bound water molecule as in Fig. 2, then there will be the loss of the hydrogen bond and also of the dispersion energy between the enzyme and the −OH group. The latter is worth ~1–2 kcal mol^{-1} (ref. 19) so the hydrogen bond

is worth 3.5–4.5 kcal mol^{-1}. If it is easier to bind phenylalanine without displacing the water, then the bond must be stronger than this.

Case D. Deletion of a side chain when there are geometrical constraints against hydrogen bonding in an enzyme–substrate complex. The above cases assume that there are no constraints on forming hydrogen bonds in the enzyme–substrate complex. When, as in equation (8), there is poor hydrogen bonding

$$\text{E-H}\cdots\text{OH}_2+\text{HOH}\cdots\text{B-S}=[\text{E-H B-S}]+\text{HOH}\cdots\text{OH}_2 \quad (8)$$

because the intermolecular distance between −H and −B is too great, there is just one good hydrogen bond on the right-hand side but two on the left of the equation. Deletion of −H may increase the affinity of the enzyme for the substrate because with the mutant enzyme there is one good hydrogen bond on the right but now only one on the left. Mutation of Thr→Ala 51 (ref. 12) is an example of this, as is Ser→Gly 35.

Case E. Deletion of a side chain on the enzyme or a group on the substrate that allows access of water between enzyme and substrate in their complex. It was suggested in Case C that phenylalanine binds to the tyrosyl-tRNA synthetase without displacing the bound water molecule but with unfavourable van der Waals' repulsion. On deletion of a large side chain from the enzyme, there could perhaps be adequate room for a water molecule to occupy comfortably the gap left by the deleted side chain, as in equation (9).

$$\text{E HOH}\cdots\text{OH}_2+\text{HOH}\cdots\text{B-S}=\text{E HOH}\cdots\text{B-S}+\text{HOH}\cdots\text{OH}_2 \quad (9)$$

A hydrogen-bond inventory shows that the number of hydrogen bonds may be formally conserved, as in Case A, equation (6). The energetics are expected to be similar to Case A for −B being an uncharged side chain. When −B is charged, as in Case B, the retention of solvent water by the charged group in the mutant enzyme–substrate complex will tend to attenuate the effects described in Case B.

Biological specificity

The classical view of biological specificity is that binding energy is provided by dispersion forces and the hydrophobic effect, whilst complementary hydrogen bonds and salt bridges give specificity[16,20]. This study shows that, irrespective of any small structural effects that occur on deletion of side chains, a side chain that forms a hydrogen bond between the enzyme and an uncharged group on a substrate provides only 0.5–1.5 kcal mol^{-1} of binding energy relative to the absence of the side chain. This means that an unpaired uncharged hydrogen bonder provides a factor of only 2.5–15 or so towards specificity. But the absence of a group on the enzyme or a substrate that should form a hydrogen bond with a charged group (as in Cases B and C) affects binding by ~4 kcal mol^{-1} and is worth a factor of 1,000 in specificity. Thus, specificity is caused to some extent by hydrogen bonding but is best mediated by charged residues.

In principle, the same reasoning may be applied to the contribution of hydrogen bonding in base pairing during DNA replication or transcription. There is, however, one important difference when analysing, for example, G·T and A·C mispairing. All the cases discussed here concern the removal of groups so that no unfavourable steric interference is set up between the enzyme and substrate. But, if in base mispairing, G·T takes up the same overall geometry as an A·T base pair and A·C the same as a G·C pair, unfavourable steric and electrostatic interactions will be set up between >NH groups. These effects will compound the loss of hydrogen bonds in the mispairs. In general, unfavourable steric interactions are an important element in specificity, as van der Waals' repulsion energies are such a strong function of interatomic distance. High specificity by steric repulsion is the basis of double-sieve sorting of amino acids by the aminoacyl-tRNA synthetases[21]. Thus, two important components of biological specificity are the avoidance of unsolvated charges and unfavourable steric interactions between enzyme and substrate.

New quasars with $z = 3.4$ and 3.7 and the surface density of very high redshift quasars

C. Hazard* & R. McMahon†

* Department of Physics and Astronomy, University of Pittsburgh, Pittsburgh, Pennsylvania 15260, USA
† Institute of Astronomy, Madingley Road, Cambridge CB3 0HA, UK

It has been suggested that there is a sharp decline in the space density of quasars beyond redshifts $z \sim 3.5$[1]. We describe here the discovery on a UKST (UK Schmidt telescope) low-dispersion IIIaF objective prism plate of a QSO (quasistellar object) with $z = 3.7$, which is the second highest redshift QSO known and, moreover, lies in the same region in which a QSO with $z = 3.61$ has already been reported[2]. We also note a QSO with $z = 3.4$. Before these observations, only seven QSOs with $z \geq 3.4$ were known throughout the whole sky. When compared with the results of a search for QSOs with $2.7 < z < 3.3$ on the same plate, these observations do not support suggestions of a $z \sim 3.5$ cut-off in the QSO distribution[1], but rather support the suggestion of a steady decline from $z \sim 2$. We show here that deep searches over small areas of sky are unlikely to be successful in discovering QSOs at $z > 4$ and that such searches must be carried out over very large areas, even if only to a moderate limiting magnitude of $m(R) \sim 19$.

The UKST, in combination with the 44-arc min objective prism and IIIaJ plates, has proved a powerful tool for the detection of QSOs by their Lyα emission up to $z = 3.3$, a limit set by Lyα then passing beyond the red limit of the IIIaJ response at ~5,200 Å. This particular prism has usually been considered to have too low a dispersion to be used effectively with a IIIaF emulsion, which has a red limit at ~6,800 Å and can, in principle, detect QSOs up to $z \approx 4.5$. However, the discovery of the $z = 3.52$ QSO1159+123 (ref. 3) has shown that UKST IIIaF prism plates can be used to find high-z QSOs; the selection problems caused by irregularities in the spectral response of the

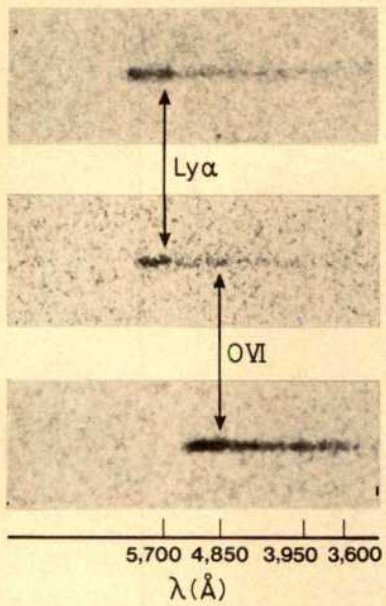

Fig. 1 Objective prism spectra of 0055−2659 reproduced by courtesy of the UK Schmidt Telescope Unit.

IIIaF emulsion can be minimized by using auxiliary IIaD and IIIaJ prism plates to check selected candidates. The rapid decrease of the prism dispersion with increasing wavelength produces in the majority of IIIaF prism spectra a strong enhancement of the continuum emission near their red limits. This makes emission lines above 6,000 Å difficult to distinguish and limits the maximum redshift attainable to $z \cong 3.9$. As QSOs with $z \leqslant 3.3$ are better found on IIIaJ plates, the useful range of the IIIaF plates is $3.3 \leqslant z \leqslant 3.9$.

The new QSOs were discovered on a set of high-quality plates centred on RA 00 h 53 min, dec. −28° 03′, the same field in which the $z = 3.61$ QSO DHM0054−284 (ref. 2) was found. Their positions, magnitudes and estimated redshifts are given in Table 1. These were the only new objects found in our search about which we were reasonably certain on the basis of the prism data alone, although we would certainly have included DHM0054−284 in Table 1 if it had not already been identified. The objective prism spectra of the $z = 3.7$ QSO0055−2659 are reproduced in Fig. 1 and illustrate how the IIaD and IIIaJ spectra are used to support the identification. The Lyα emission visible in both the IIIaF and IIaD spectra, the OVI emission visible in the IIaD and IIIaJ spectra and the heavy absorption in the IIIaJ continuum, all combine to support the identification as a high-z QSO. Our measurements of the various emission features are presented in Table 2 and the estimated redshifts are in such good agreement that we had no hesitation in confirming from the prism data alone the identity of 0055−2659 as a QSO with $z = 3.7 \pm 0.05$. Its strong blue continuum, extending to at least 800 Å in the rest frame, makes this bright QSO particularly suitable for ground-based absorption line studies and for satellite observations. The $z = 3.4$ QSO0042−2627, could also be identified with confidence. The emission line in the IIIaF spectrum is too strong to be an artefact of the emulsion response and it is just visible at the extreme limit of the IIIaJ spectrum.

Observations by A. Boksenberg (personal communication) on the 2.5-m Isaac Newton telescope on La Palma have already confirmed the estimated redshift for 0055−2659, and those by A. Boksenberg and W. L. W. Sargent (personal communication) on the Palomar 5-m telescope, that of 0042−2657. The measured redshifts are 3.67 and 3.4, respectively, which establishes 0055−2659 as second in redshift only to the $z = 3.78$ radio-selected QSO2000−330 (ref. 4) and as the highest redshift QSO selected by purely optical techniques. Of the nine known QSOs with $z \geqslant 3.4$, three have now been discovered in the 36 square degrees of one UKST field, a success rate that raises questions regarding the failure of previous high-z QSO surveys going to fainter magnitude limits.

The failure to find any QSOs with $z > 3.8$ in the earlier special searches over areas of only a few square degrees must be considered in light of the fact that even in the redshift range $3 < z \leqslant 3.3$ QSOs are not exactly common. Although even weak emission-line QSOs in this redshift range are readily found on Schmidt Telescope IIIaJ prism plates, and such plates covering several thousands of square degrees have now been searched, the latest QSO catalogue[5] lists only 38 in this redshift interval. As far as we know, the highest number of QSOs with $3 < z \leqslant 3.3$ on a single Schmidt plate has been found by C.H. and W. L. W. Sargent (unpublished data) on a UKST plate centred on RA 15 h 00 min, dec. +11° 00′. They have confirmed by slit spectroscopy a total of nine such QSOs with $B(J) < 20$, with only a few candidates remaining to be examined so far. This represents a decrease by a factor of at least 10 from the number of QSOs they found around $z = 2$ in the same redshift interval. Hazard[6] claims that this steep decrease cannot be attributed to a bias against the selection of the higher-z QSOs but corresponds to a decrease in the co-moving density of emission-line QSOs for $z \geqslant 2$. He further suggests that the failure to detect QSOs around $z = 4$ over small areas of sky, rather than implying a QSO cut-off at $z \sim 3.5$, represents an extrapolation of the observed decline between $z = 2$ and $z = 3$ to higher redshifts.

Assuming $m(J) - m(R) \approx 0.7$ for QSOs around $z = 3$ (see Fig. 1 in ref. (2)) and a rate of decrease of a factor of 10 per unit redshift interval, the extrapolation gives an expected six QSOs per UKST field with $m(R) < 19.3$ and $3.3 < z < 3.9$. The discovery of three QSOs in the 0053−2803 field with $m(R) \leqslant 18$ is consistent with this estimate, particularly as some of the $z > 3$ QSOs in the 1500+1100 field are weak emission line objects that would probably not have been detected on the IIIaF plate. The only surprise, perhaps, is that all are so bright, as, for the usual power law luminosity function, the majority would be expected to lie near the plate limit at about 19 mag; we have searched carefully for fainter candidates, but without success, apart from a possible weak line $z = 3.5$ QSO with $m(R) = 18.4$ at RA 01 h 01 min 15.7 s, dec. −26° 53′ 26″.

Any significant clustering of high-z QSOs or any difference in the redshift distribution in different regions of sky could invalidate the above comparison. We have, therefore, attempted a direct comparison of the QSO densities between $3.3 < z < 3.9$ and $z \sim 3$ by searching the IIIaF plate for QSOs with $2.7 < z < 3.3$ using the same procedures adopted in the search for the higher-redshift objects. Genuine QSOs with $z < 3.3$ can be unambiguously identified by their Lyα emission in the IIIaJ spectra. We did, indeed, find that not all the $z \sim 3$ QSOs that are recognizable on the IIIaJ plates can be found on the IIIaF plates, showing that our survey for objects with $z > 3.3$ is also probably incomplete. The search yielded a total of 11 QSOs with $2.7 < z < 3.3$. When compared with our results for $3.3 < z < 3.9$, this represents, for a magnitude-limited sample and for $\Delta z = +0.6$, a decrease in QSO density by a factor of 3, which is in satisfactory agreement

IIIaJ	4,875	OVI	3.71
		Adopted redshift 3.70 ± 0.05	

with the decrease by a factor of ≥ 10, between $z = 2$ and $z = 3$ found on the 1500+1100 plate. These results are more consistent with a steady decline in the QSO density above $z > 2$ than with a cut-off in the QSO distribution at $z \sim 3.5$. This could imply that the birth of the majority of QSOs occurred at $z \sim 2$ and could have important implications regarding the epoch of galaxy formation and the rate of growth of the massive galactic nuclei that are generally believed to be the primary QSO energy sources.

Our results, relating both to the fall in the surface density of QSOs with increasing redshift and to the apparent lack of a strong magnitude dependence in the number of high-z QSOs, are consistent with the type of combined luminosity and density evolution proposed by Koo[7]. According to Koo, the luminosity function at $z = 2.15$ corresponds to a steep power law dependence at the bright end with the QSO density rising rapidly with decreasing brightness up to $M_B = -28$, where there is a transition to a much flatter distribution for the fainter objects. With increasing redshift the basic form of the distribution remains unaltered, but it is displaced in the log ρ/M plane so that the turn-over point shifts both to brighter absolute magnitudes and to lower densities. For sufficiently high redshifts the observed QSOs will be dominated by those lying in the flat region between the turn-off point and the absolute magnitude corresponding to the limiting apparent magnitude. The occurrence of a bright high-z QSO in a given field is thus as probable as a QSO near the limiting magnitude, although, in practice, the former is the one more likely to be selected; that all known high-z QSOs are relatively bright is therefore no accident. In a magnitude-limited sample, the number of QSOs in a given redshift interval will decrease with increasing redshift at a rate approximately corresponding to the degree of density evolution, but modified by the different rates of displacement of the turn-off point and the limiting magnitude; if there is a maximum QSO luminosity, the numbers will decrease more rapidly when it comes into effect.

It is easy to show, by a similar extrapolation to that used earlier, that the expected number of QSOs to $m(R) \sim 21$ with $4 < z < 5$ is less than 0.1 per square degree, a figure quite consistent with the reported null detections over an area of 5 square degrees[1]. Furthermore, this figure is only weakly dependent on the magnitude limit and about half of the QSOs will be brighter than 19 mag. Deeper surveys cannot be used to compensate for a drastically reduced search area and it follows that searches for very high-z QSOs, carried out over small areas of sky, have a very low probability of success. Searches over very large areas, even if only to a moderate limiting magnitude of $m(R) \sim 19$, offer the only realistic hope.

We have demonstrated the usefulness of the UKST low-dispersion IIIaF objective prism plates in high redshift surveys, at least up to $z \sim 3.7$. The extension to $z > 4$ will probably require the use of the new higher-dispersion prism with appropriate filters or the use of broad-band colours. The strong Lyα emission of all presently known high-z QSOs has at least removed the worry that increasing absorption due to intervening gas or dust might prevent their discovery when using slitless spectroscopy techniques. Finally, the observations presented here should encourage more active searches for these objects which provide the only means we have at present for probing the early history of the Universe.

We thank the UKST for help and for excellent plate material and R. Terlevich for his part in the development of the Cambridge objective prism programme. We also thank M. Irwin for providing the magnitude measurements from the Cambridge APM, R. Sword for the reproduction of the objective prism spectra and Dr D. C. Koo for useful discussions.

Infrared Seyferts: a new population of active galaxies?

M. H. K. de Grijp*†, G. K. Miley†‡, J. Lub† & T. de Jong§

* ESTEC-SA, Postbus 299, 2200 AG Noordwijk, The Netherlands
† Sterrewacht Leiden, Postbus 9513, 2300 RA Leiden, The Netherlands

§ Sterrenkundig Instituut, Universiteit van Amsterdam, Roetersstraat 15, 1018 WB Amsterdam, The Netherlands

A Seyfert spectrum is one of the most important indicators of nuclear activity in galaxies. It is characterized by broad emission lines with high ionization. Most known Seyferts have been found indirectly, for example, by the presence of a strong ultraviolet continuum (Markarian galaxies) or of intense radio emission (broad/narrow-line radio galaxies). Here, we present a new method for finding hitherto unknown Seyferts based on their mid-infrared spectra and we show using data from the Infrared Astronomical Satellite (IRAS) that this method has a success rate of ~70%. One Seyfert, so discovered, contains the most luminous infrared nucleus known so far. X-ray surveys are also an efficient means of finding new Seyferts and QSOs (quasistellar objects)[1,2], but tend to reveal samples at considerably higher redshifts and lower space density. We believe that 'infrared' Seyferts may soon outnumber those detected by other methods.

IRAS[3] has detected many thousands of galaxies, principally at wavelengths of 60 and 100 μm. Most galaxies detected in flux-limited samples at these wavelengths[4,5] have relatively steep infrared spectra with indices $\alpha \sim -2.5$ (defined by $S_\nu \propto \nu^\alpha$, where S_ν is the flux density at frequency ν). This cold infrared emission (~ 30 K) is believed to be produced in the disks of spiral and interacting galaxies[5–7].

On the other hand, for most known cases of infrared emission from the nuclear region of active galaxies, the spectrum is significantly flatter in the infrared. For example, NGC1068 has a 250 K mid-infrared component whose spectrum peaks near 30 μm[8–11] and which originates from a region ~60 pc in size. A similar component is observed in 3C390.3[12]. Quasars also have relatively flat infrared spectra[13].

These considerations prompted us to investigate whether a relatively flat infrared spectrum may be an indicator of nuclear activity. We selected a subsample of 'warm' objects from the partially completed IRAS survey, all at high galactic latitude ($|b| > 20°$) and with spectral indices between 25 and 60 μm of $-1.25 < \alpha < -0.5$. These wavelengths were chosen as the most efficient for indicating flat-spectrum nuclear infrared emission. A cold galactic disk would dominate the 100–60-μm spectrum, possibly masking a warm nuclear component.

The IRAS sources so defined were identified using the Palomar Sky Survey and ESO/SRC (European Southern Observatory/Science Research Council) plates. After excluding objects that were clearly galactic (stars, small H II regions, planetary nebula), the remainder (54 objects) were published in IRAS Circular 11 as a list of candidate active nuclei[14].

Spectra were taken of 40 of these objects (Table 1). The observations were made in photometric weather between 7 and 9 March 1984 with the Image Dissector Scanner (IDS) on the Boller and Chivens spectrograph at the 3.6-m ESO telescope at La Silla with a dispersion of 172 Å mm^{-1}. This resulted in a wavelength coverage of 3,800–7,000 Å, with a resolution of 11-Å FWHM. The exposure times for the objects discussed in this letter was 10 min. Wavelength calibration, flatfielding and flux calibration were carried out in the standard way with the ESO IHAP system (Image Handling and Processing), using the white dwarfs W485 and L745−46A as standard stars.

Our results are summarized in Table 1. In classifying the optical spectra, we adopt the scheme of Baldwin *et al.*[15] in which

Table 1 Results of the spectroscopic observations

Column 1 lists the IRAS designation as given in IRAS Circular 11. Column 2 codes for the shape of the infrared spectrum ($\alpha > -1.25$): F1 marks a flat spectrum between 25 and 60 μm; F2 denotes that the 25-μm flux is unreliable, but that the spectrum is flat between 60 and 100 μm. The measured redshifts are given in column 3 (the error is smaller than 0.001, except for those marked ':'. The corrected [OIII] linewidths (FWHM deconvolved with the instrumental response) are given in column 4 and the typical uncertainty is 60 km s^{-1}. Column 5 gives the type of optical spectrum and information about the number of optical counterparts possibly associated with the infrared sources.

Seyfert galaxies have high ionization with [OIII]λ5007/$H\beta > 6$ and [NII]λ6584/Hα > 0.4. All the spectra defined in this way have broad resolved [OIII] lines >250 km s^{-1} full-width to half maximum (FWHM), also typical of Seyferts[16–18]. Although higher resolution spectra are clearly necessary, the results obtained up to now suggest that on average the widths of the forbidden lines are substantially larger (57% broader than 600 km s^{-1}) than in previous surveys[19] (15% broader than 600 km s^{-1}), which may be an effect of the large fraction of Seyfert IIs in this sample, as they are known to have broad forbidden lines[16].

One of these infrared Seyferts (Fig. 1) is IRAS1051−273P11. Our measured redshift of 0.161 combined with the IRAS 25-μm

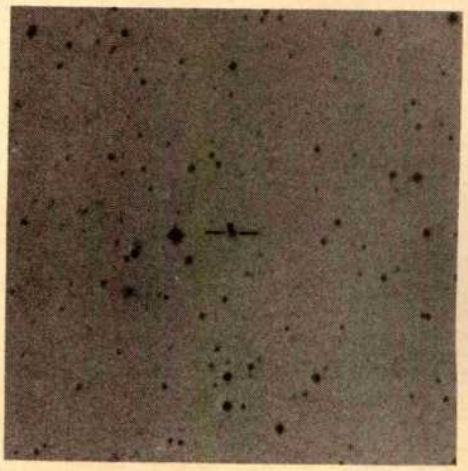

Fig. 1 A reproduction of the ESO/SRC J-plate of IRAS1051−273P11. North is up, east to the left; the picture encompasses 5×5 arc min on the sky. Close to the north of this Seyfert galaxy is a star.

flux density of 0.4 Jy results in a 25-μm luminosity of $10^{25.3}$ W Hz^{-1}, which is an order of magnitude larger than that of the mid-infrared component of either NGC1068 or 3C390.3, making it the most luminous Seyfert galaxy known in this wavelength range. If the 25-μm flux is thermal in origin, arguments analogous to that used for NGC1068[11] would require heating by an ultraviolet source of 2×10^{12} L_0.

In Table 1, 24 objects have reliably-determined flat infrared spectra between either 60 and 25 μm or between 60 and 100 μm. Of these flat-spectrum objects 17 (that is, 71%) have Seyfert spectra, which should be compared with a Seyfert rate of ~10% for Markarian objects. Hence a flat infrared spectrum is a remarkably efficient predictor of the Seyfert phenomenon and a preliminary analysis of IRAS circular 16 (ref. 20), which contains sources with similar infrared colours, seems to confirm this picture. Also, the IRAS source 0421+040P06[21,22], which has a 25-60-μm spectral index within our selected range, has been found recently to have a Seyfert-type spectrum.

Extrapolation of our results to the all-sky survey indicates that the IRAS database contains several thousand Seyferts, compared with ~330 Seyferts previously known[23]. Taking the redshifts of the 21 Seyferts in Table 1 and assuming a Hubble constant of 75 km s^{-1} Mpc^{-1}, the space density of the infrared Seyferts, determined using the V/V_{max} method, is 1.7×10^{-4} Mpc^{-3}, 2.5 times greater than values based on the Markarian Seyferts[24]. As no correction was made for incompleteness, this should be viewed as a lower limit. The fractional error based on this sample is 40%, but combination with recent new data yields the same figure with a 25% uncertainty.

Seyferts found through X-ray surveys are quite distinct in their properties from the infrared Seyferts; the space density of the X-ray objects is more than an order of magnitude lower and they are on average 10 times further away. Indeed a large fraction of them may more properly be called QSOs.

How do the infrared Seyferts differ from the Markarian Seyferts and why have they not been discovered before? The possibility that, using infrared criteria, we select more distant galaxies than does the Markarian method is improbable as there is no significant difference in the redshift distribution of our sample compared with the Markarian one[24] and both have median redshifts of 0.03. It is more probable that the infrared Seyferts are systematically fainter in the optical than the Markarian Seyferts[24]. The Markarian catalogue becomes incomplete below an apparent magnitude of 15.5; although there is considerable uncertainty in the brightness of the infrared Seyferts, our initial estimates indicate that several are fainter than this magnitude.

It is also not unexpected that a large number of infrared Seyferts would be missed by the Markarian catalogue. The same dust that is presumably responsible for the infrared emission would significantly redden the non-thermal visible light from

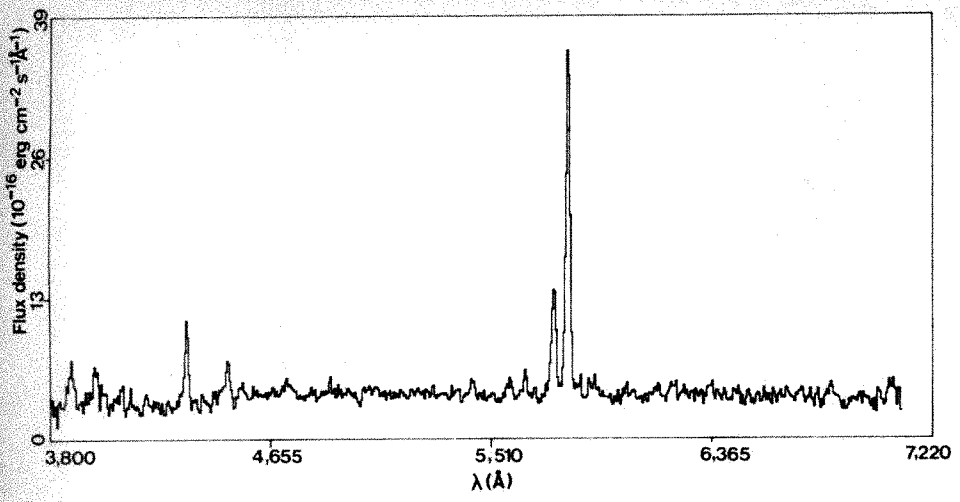

Fig. 2 The spectrum of IRAS1051−273P11 taken with the 3.6-m telescope at La Silla. A correction for the instrumental sensitivity has been applied, which tends to increase the noise on the edges of the spectrum. Note that Hα is redshifted out of the wavelength range.

the nucleus, thereby reducing or eliminating the ultraviolet excess required for inclusion in the Markarian survey. Obscuration by dust outside the nucleus could also significantly affect the detectability. Hence the Markarian (ultraviolet) and IRAS (infrared) techniques are complementary indicators of the Seyfert phenomenon.

We show here that an infrared survey can be a highly efficient means of discovering new Seyferts. The nature of the objects selected in this way and their relationship with other active galaxies will be studied further. Comparison of the infrared properties with the intensities and profiles of the narrow emission lines will give unique information about the role of dust in the narrow line region.

A study of the visible morphology and the radio properties of the infrared Seyferts is of particular interest. These Seyferts may be a link between optically-selected Seyferts, which are associated predominantly with spirals, and the radio-selected ones, which are in elliptical galaxies.

Finally, in addition to the all-sky survey discussed here, a deeper survey of limited regions of the sky was carried out by IRAS. This survey should reach factors of 5–15 times deeper than the all-sky survey and contain several thousand sources and should enable infrared Seyferts to be detected out to redshifts of >0.5 where the effects of cosmological evolution are believed to play an important role.

This work is based on observations made at the European Southern Observatory, La Silla, Chile. G.K.M. is on assignment from the European Space Agency, Noordwijk, The Netherlands.

On the binary nature of cosmic γ-ray burst sources

S. A. Rappaport & P. C. Joss

Center for Space Research, Center for Theoretical Physics and Department of Physics, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139, USA

The basic nature of cosmic γ-ray burst sources[1] has remained a mystery. Schaefer[2] and Schaefer *et al.*[3] recently discovered three images on archival photographic plates probably due to optical flashes from the error boxes of three γ-ray burst sources. This discovery opens up the possibility of ground-based optical studies of these objects (see, for example, ref. 4) and provides an important new set of data that can constrain models significantly (see, for example, ref. 5 and references therein) for these intriguing sources. London and Cominsky[6] have considered a model for the optical flashes, wherein γ-ray bursts are emitted by a collapsed object in a close-binary stellar system and a small fraction of the γ radiation is reprocessed into optical radiation in the surface layers of the companion star (see refs 7 and 8 for possible alternative explanations). Based on their own estimates of the time, τ, required to reprocess the γ radiation into optical light, London and Cominsky concluded that a binary model would not account for the observed optical flashes. They considered, however, only main-sequence stars and hydrogen-depleted degenerate dwarfs as possible companion stars. We reconsider here the binary model and conclude that it is viable. In particular, under the assumption that the optical flashes were produced by γ-ray bursts of about the same intensity as those observed, we find that nearby (≲100 pc) binary systems with secondaries whose masses are less than ~0.06 $M_\odot$ can fit all the observational constraints for the three optical/γ-ray pair events (hereafter 1928/1978, 1944/1979 and 1901/1979; see Table 1).

We have considered a wide range of parameters for the binary systems in which the optical flashes may be produced. Here we have chosen specifically a sequence of models that could plausibly represent the evolution of a compact binary during the phase when the mass of the secondary is reduced (by mass transfer) from ~1 $M_\odot$ to almost planetary values. We adapted the results from a binary evolutionary sequence calculated by Rappaport, Verbunt and Joss[9], in which the initial binary consists of a collapsed star of mass 1.2 $M_\odot$ orbiting a 1.0 $M_\odot$

main-sequence dwarf; the early evolution is dominated by the loss of angular momentum due to magnetic braking, whereas the later evolution is dominated by the emission of gravitational radiation (see model CMB 4 in ref. 9 for details). For the present work, we took the final mass of the primary to be no greater than 1.4 $M_\odot$ and adjusted the orbital separation accordingly. The evolution of the mass, radius and effective temperature of the companion star in this evolutionary sequence, as well as the orbital period and mass transfer rate, is shown in Fig. 1. As the mass of the secondary, M_c, decreases from 1.0 $M_\odot$ to 0.1 $M_\odot$, its properties remain close to those of a main-sequence star of the same mass. For $0.03 \leq M_c \leq 0.1\ M_\odot$, the secondary star is out of thermal equilibrium and evolving toward a degenerate state; for $M_c \leq 0.03\ M_\odot$, the internal properties of the secondary are essentially those of a completely degenerate star. The results described below are not especially sensitive to the details of this evolutionary scenario; the calculated optical fluences depend primarily on the current orbital separation and the radius and effective temperature of the secondary.

We do not attempt here to model the γ-ray burst emission mechanism, but assume merely that γ radiation is emitted isotropically by the collapsed star. For each of the binary models, we consider γ-ray burst energies, E_γ, in the range of 10^{35}–10^{39} erg and use an approximate expression for the average γ-ray fluence, F_{γ_c}, that is absorbed over the facing hemisphere of the companion star

$$F_{\gamma_c} = \frac{E_\gamma(1-\alpha)\{1-[1-(R_c/a)^2]^{1/2}\}}{4\pi R_c^2} \simeq \frac{E_\gamma}{8\pi a^2} \simeq 1.6\times10^{14}\left[\frac{E_\gamma}{10^{37}\ \mathrm{erg}}\right] \times\left[\frac{a}{5\times10^{10}\ \mathrm{cm}}\right]^{-2} \mathrm{erg\ cm^{-2}} \quad (1)$$

where α is the γ-ray albedo (taken to be 0.2), R_c is the radius of the secondary and a is the orbital separation.

The γ radiation, which penetrates the surface layers of the companion star, is thermalized and re-radiated as optical light (and possibly also as infrared and ultraviolet radiation). We have carried out Monte Carlo calculations to determine the column density beneath the stellar surface at which the burst energy is deposited and find that for typical burst spectra, the amount of energy deposited falls off approximately exponentially, with an e-folding column density of ~8–10 g cm^{-2} (see also ref. 6).

London and Cominsky[6] have estimated the reprocessing time, τ, and find that for γ-ray fluences (at the companion) in the range $10^{12.4} < F_{\gamma_c} < 10^{14.8}$ erg cm^{-2}, the value of τ can greatly exceed the duration of the γ-ray burst. Their estimates, however, are only of order of magnitude accuracy and neglect the effects of the hydrodynamic expansion of the envelope of the secondary. Therefore, we consider here a rather wide range of reprocessing times of 5–500 s. The lower limit is set by the typical duration of the γ-ray burst events[10,11], whereas the upper limit is set by the lack of trailing of two of the detected optical images[2,3] (see Table 1). For simplicity, we assume that during the optical flash the heated hemisphere of the companion star radiates uniformly for a time τ at a constant temperature, $T_b = [F_{\gamma_c}/\sigma\tau + T_{qui}^4]^{1/4}$ (see also ref. 6), where σ is the Stefan-Boltzmann constant and T_{qui} is the effective temperature of the companion star in quiescence between γ-ray burst events.

We calculated the optical fluence at the Earth in a 1,000-Å-wide band centred at 4,350 Å (a blue band that approximates the response of the archival plates on which the optical flashes were discovered[2,3]) for each model in our evolutionary sequence and for each of several X-ray burst energies within the range prescribed above. For simplicity, we assumed a typical aspect angle of 45° between the line of sight and the line connecting the centres of the binary components. We also computed the distance to the source implied by the measured γ-ray fluence of each particular event at the Earth (see Table 1) and the assumed γ-ray burst energy, and the quiescent visual magnitude m_{qui} of the companion star. We require that $m_{qui} > 24$ for a model to be consistent with the lack of any prominent optical candidates[12–15] in the error boxes of the three γ-ray burst sources that have been associated with optical flashes[2,3].

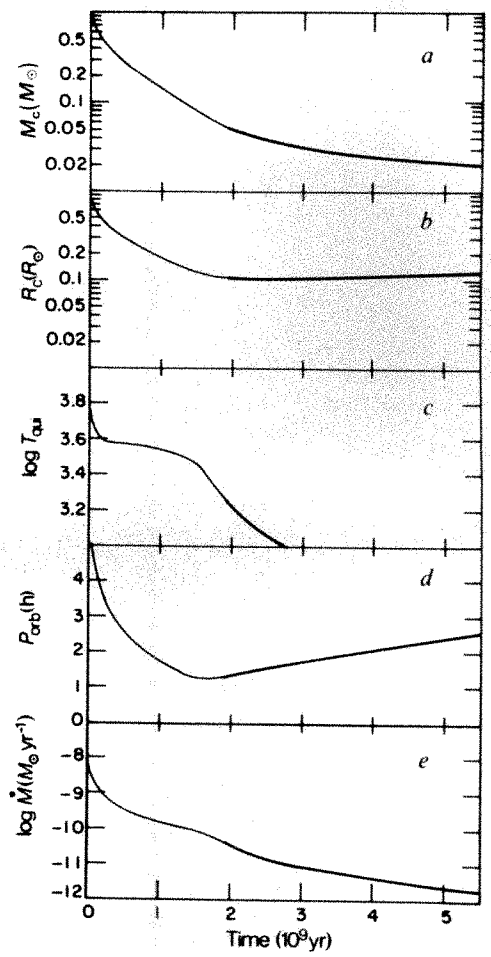

Fig. 1 Evolution of a compact binary system under the influence of magnetic braking and gravitational radiation (adapted from model CMB4 of ref. 9). The initial binary system consists of a 1.0 $M_\odot$ main-sequence dwarf companion and a 1.2 $M_\odot$ collapsed star in a 6.3-h orbit. The quantities plotted as functions of elapsed time in frames *a*–*e* are the mass, radius and quiescent effective temperature of the secondary star, the orbital period and the rate of mass loss from the secondary, respectively. The heavy portion of each curve corresponds to binary models which yield optical flashes (due to the reprocessing of γ-radiation) with properties similar to those observed[2,3]. The heavy portion of the effective temperature curve is qualitatively correct, but its quantitative details are highly uncertain.

We show sample results of our calculations in Fig. 2 for the 1928/1978 source (results for the 1944/1979 and 1901/1979 sources being similar). The γ-ray fluence of the 1978 event was ~3×10^{-4} erg cm^{-2} s^{-1}, whereas the blue magnitude of the optical flash on the archival plate was 10.2 (ref. 2). This corresponds to a blue fluence, F_{opt}, of ~$1{\cdot}4\times10^{-6}\ \mathcal{R}$ erg cm^{-2}, where $\mathcal{R}$ is a correction factor that takes into account the reciprocity failure[16] of the photographic emulsion. If the entire optical event transpired during the exposure of the plate, we obtain (from data presented in ref. 16) $\mathcal{R} \simeq (\tau/T_{exp})^{0.18}$, where T_{exp}, the exposure time of the plate, is 2,700 s for the plate on which the 1928 optical flash was discovered.

The results in Fig. 2 show the predicted values of F_{opt} as a function of the assumed γ-ray burst energy. Each burst energy corresponds to a unique distance to the source that generated the 19 November 1978 event if the model is to account for the measured γ-ray fluence. We show the results for binary models with several different values of M_c and $\tau_\odot$. (Our estimates for

§ In a 1,000-Å band centred at 4,350 Å, for an assumed value of $\tau = 5$ s.
‖ Limit on the duration of the optical flash derived from the lack of trailing of the observed images.

F_{opt} are effectively lower limits, as the presence of a disk or ring of matter in the binary stellar system would probably increase the total blue fluence resulting from reprocessing.) The measured value of F_{opt}, which varies by up to a factor of two for different choices of τ because of the variation of the reciprocity correction, is also indicated.

We consider the agreement between the model calculations and the observations to be excellent when the following sources of error are taken into account: (1) the uncertainties in establishing the apparent magnitude of the optical flash (including uncertainties in reciprocity corrections for old emulsions[16] and uncertainties in comparing the untrailed flash image with trailed reference-star images[16]); (2) the uncertainty in the measured γ-ray fluence; (3) the unknown difference between the strength of the γ-ray burst that produced the 1928 optical flash and the observed γ-ray burst of 1978. In the light of these uncertainties, we consider agreement to within a factor of ~5 between the predicted and measured optical fluences to be an acceptable fit (see Fig. 2). In fact, as is evident from Fig. 2, there are a number of models with $M_c \leq 0.05\ M_\odot$ for which the predicted optical fluence is within a factor of ~2-3 of the measured fluence. Binary models providing acceptable fits are shown as heavy curves in Fig. 1. For each value of τ and M_c, the best-fit model roughly corresponds to the γ-ray energy that yields $T_b \simeq 8{,}500$ K and thereby maximizes the amount of reprocessed radiation in the blue band.

From the results shown in Fig. 2, we conclude that the proposed model for producing the optical flashes by reprocessing γ radiation on the surface of a binary stellar companion is viable. London and Cominsky[6] reached the opposite conclusion because they did not fully consider extremely-low-mass hydrogen-rich secondary stars. We find that the most favourable models for the 1928/1978 event are those with $M_c \leq 0.05\ M_\odot$, $T_{qui} \leq 1{,}800$ K, $E_\gamma \leq 10^{38}$ erg and distances $d \leq 50$ pc. Values of E_γ and d less than $\sim 10^{35}$ erg and ~2 pc, respectively, are allowed by the binary model, but are excluded by considerations (discussed below) that are based on the Oort limit and the diffuse cosmic X-ray background.

The same type of calculation as that represented in Fig. 2 was repeated for the 1944/1979 and 1901/1979 events. The binary models best able to account for these events are essentially the same as for the 1928/1978 event (Fig. 1). Acceptable distances are ≤100 and ≤250 pc for the 1944/1979 and 1901/1979 events, respectively.

Distances for these sources of ≤2 pc are excluded because the mass density of such systems would then exceed the Oort limit on the local density of matter in the solar neighbourhood (~0.15 $M_\odot$ pc^{-3}; see, for example, refs 12, 17 and 18). Moreover, if (1) the mean distance between sources is ≤10 pc, (2) the systems have neutron-star primaries, (3) these systems were low-mass X-ray binaries at an earlier evolutionary phase[19] and if (4) the number of such systems in our Galaxy is typical of other galaxies, then the total X-ray emission from such systems in distant galaxies would dominate the diffuse X-ray background[20].

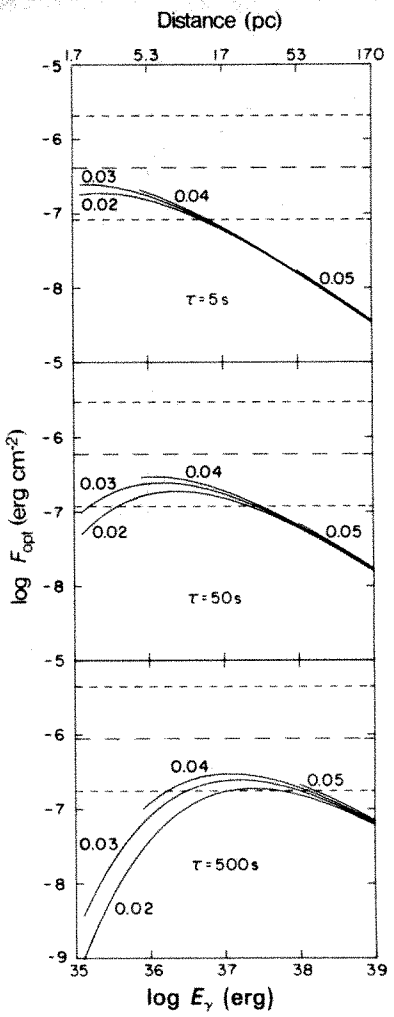

Fig. 2 Calculated optical fluences, F_{opt}, at the Earth, in a 1,000-Å band centred at 4,350 Å. The calculations are carried out for a γ-ray fluence at the Earth of 3×10^{-4} erg cm^{-2} and for a range of binary models, assumed γ-ray burst energies, E_γ, and reprocessing times, τ. The binary model is completely specified by the mass of the secondary, M_c (see Fig. 1); sample results are shown for $M_c = 0.02$, 0.03, 0.04 and 0.05 $M_\odot$. The curve for each value of M_c terminates at the point where the companion star would be visible in quiescence ($m_{qui} < 24$; see text). The long dashed line in each frame is the measured optical fluence[2] of the 1928/1978 event (see Table 1). Note that this quantity attains a somewhat different value for each of the assumed reprocessing times because of variations in the correction for reciprocity failure. The set of short dashed curves in each frame indicates a range of a factor of 5 around the measured optical fluence, within which the model fits are considered to be acceptable.

The need for more detailed calculations of the γ-ray reprocessing times is evident from Fig. 2. If we knew τ more reliably (for a given model of the secondary star and a given γ-ray fluence at the secondary), a much more restrictive range of distances to each source could be obtained.

If the reprocessing model is the correct explanation of the optical flashes from γ-ray burst sources, we have already established some very specific properties of these sources. They are binaries containing a low-mass cool secondary star, in orbit with a collapsed star (most probably a neutron star or degenerate dwarf) that is the source of the γ-ray bursts. The particular systems that produced the observed optical flashes may be relatively close neighbours of the Solar System; this inference is consistent with the unusually large measured γ-ray fluences[10,11] of the 1928/1978 and 1944/1979 events.

The type of binary system we have invoked, although yielding apparently correct γ-ray reprocessing properties, presents a difficulty that must be resolved if the model is to be viable. The mass-loss rates from the secondary lie in the range of $\sim 0.2\text{-}3 \times 10^{-11}\ M_\odot\ \mathrm{yr}^{-1}$ (Fig. 1). If this matter were accreted onto a $\sim 1\ M_\odot$ collapsed star and emitted isotropically in the X-ray range, the flux at the Earth would be

$$F_x \simeq 7 \times 10^9 \left[\frac{\dot{M}}{10^{-12} M_\odot\ \mathrm{yr}^{-1}}\right]\left[\frac{D}{100\ \mathrm{pc}}\right]^{-2} \times \left[\frac{R}{10^6\ \mathrm{cm}}\right]^{-1} \mathrm{erg\ cm^{-2}\ s^{-1}} \quad (2)$$

where R is the radius of the collapsed star. The measured X-ray flux from the 19 November 1978 source in quiescence is $\sim 10^{-13}$ erg cm^{-2} s^{-1} (ref. 21), which is ~ 5 orders of magnitude below the level implied by equation (2) for a neutron star, at a distance of $\leqslant 100$ pc, accreting at $\geqslant 10^{-12}\ M_\odot\ \mathrm{yr}^{-1}$. This dilemma may be resolved if there is a reduction or cessation in the rate at which matter is steadily accreted onto the collapsed star when the mass-loss rate from the secondary falls below some critical value. (We note that this picture may support some theoretical ideas concerning the nature of γ-ray bursts[22].) It is also possible that the accretion-driven luminosity will be emitted at ultraviolet or very soft X-ray energies when the accretion rate is very low.

We thank L. Greenhill for contributing to the initial phases of this work, L. Cominsky, R. London, F. Melia, G. Ricker and B. Schaefer for useful discussions, T. Loredo for assistance with the computer programming and S. Black for the preparation of the manuscript. This research has been sponsored in part by the National Aeronautics and Space Administration under contracts NAS5-24441 and NAGW-442 and grant NSG 7643, and by the NSF under grant AST-8217451.

Theory of radar imaging of internal waves

Werner Alpers

Institut für Meereskunde, Universität Hamburg, and Max-Planck-Institut für Meteorologie, Bundesstrasse 55, 2000 Hamburg 13, FRG

Radar images taken over ocean areas, in particular, those obtained by the synthetic aperture radar (SAR) onboard the American Seasat satellite in 1978[1,2], sometimes show features that seem to be surface manifestations of oceanic internal waves[3-11]. Here I present a theory explaining the large radar signatures of internal waves in which the imaging is attributed to variations in the short-scale surface roughness induced by current variations associated with internal waves.

Figure 1 is an example of Seasat SAR image of coastal waters west of Portugal showing surface expressions of nonlinear internal wave trains propagating towards the coast. The internal wave groups are believed to be generated at the continental shelf break by interaction of the tidal current with underwater bottom topography. Within each group the wavelength decreases with distance from the leading crest, indicating that they represent nonlinear dispersive wave trains; their partly irregular structure is attributed to refraction effects caused by the shoaling bottom and to interactions with the current field.

It may seem surprising that internal waves can generate such large signatures in radar imagery. These signatures must orginate from the sea surface, as the penetration depth of the microwaves emitted by the radar in the sea water is only a fraction of their wavelength. The radar senses the short-scale roughness of the ocean surface by means of Bragg scattering. Thus, the radar signatures must be the result of a modulation of the short surface waves, generated by interactions with the internal waves[12]; this modulation can either be achieved by surface films (slicks) that accumulate in flow convergence zones and damp the short surface waves there[13], or by hydrodynamic interaction of these waves with the horizontal surface current associated with internal wave motion[14-17].

The first mechanism is often active in coastal waters where surface films, either of natural or anthropogenic origin, are present. These films, even when monomolecular, damp short surface waves very strongly[18-20], reducing the radar reflectivity accordingly. When slicks modulate the short-scale surface roughness, the radar image of an internal wave field consists of dark streaks (areas of reduced radar backscatter) on a uniform bright background. In most cases, however, the radar signatures of internal waves have double sign, which means that the corresponding radar image consists of bright and dark streaks associated respectively with enhanced and reduced radar reflectivity as compared with the local mean, indicative of hydrodynamic modulation. Although most investigators now hold that the latter mechanism is responsible for the imaging[7-9], the question of why these radar signatures are so large has not been answered satisfactorily. I have attempted to do so here using the weak hydrodynamic interaction theory in the relaxation time approximation, the crucial point being that another approximation is applicable compared with the case of the modulation of short by long surface waves[21-23].

Typical imaging radars operate at wavelengths λ_0 in the centimetre to decimetre range and at incidence angles θ of 20-70°, within which the radar backscattering is dominated by Bragg scattering[24-26]. In this case the normalized radar backscattering cross-section, σ, is proportional to the spectral energy density, E, of the Bragg waves, which have a wavelength of $\lambda = \lambda_0/2 \sin\theta$ and which travel towards or away from the antenna look-direction

$$\sigma = T(E(+2\boldsymbol{k}_0) + E(-2\boldsymbol{k}_0)) \quad (1)$$

where $\boldsymbol{k}_0$ denotes the projection of the radar wave vector on the horizontal plane and T a scattering coefficient which can be calculated from Bragg scattering theory and which depends on incidence angle, dielectric constant, radar wavelength and polarization (see, for example, refs 24, 26). The synthetic aperture radar on Seasat had a wavelength of $\lambda_0 = 0.235$ m (L-band) and operated at incidence angles of $\sim 23°$; the short waves responsible for the backscattering had a wavelength of 34 cm and a wave period of 0.47 s.

Equation (1) relates the modulation of the normalized radar cross-section to that of the spectral energy density $E(\pm 2\boldsymbol{k}_0)$ of the Bragg waves, which reduces the problem to that of the modulation of the Bragg waves by the surface current associated with internal waves.

Typically, internal waves visible on radar images have wavelengths greater than several hundred metres and wave periods >10 min; the space and time scales of the currents associated with these waves are much greater than those of the

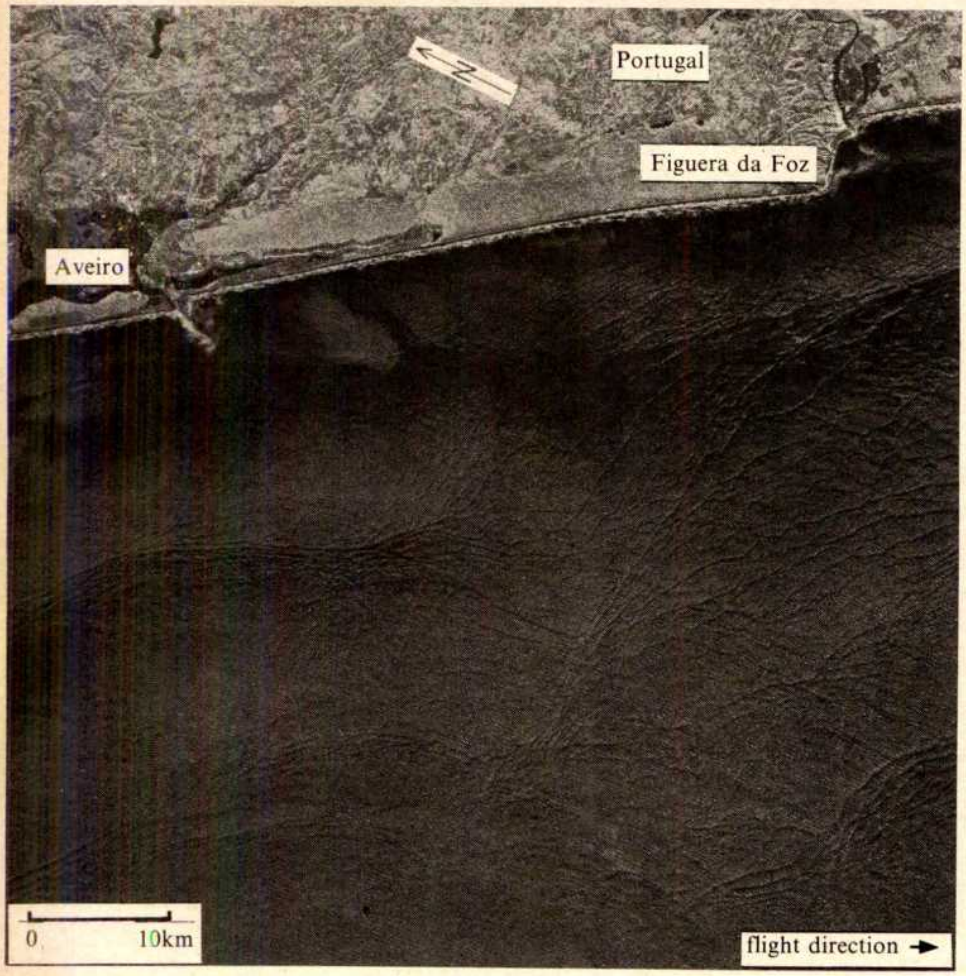

Fig. 1 Synthetic aperture radar image of Atlantic coastal waters off the Portugese coast near Figueira da Foz and Aveiro. This radar image was taken from the Seasat satellite on 20 August 1978, 21:42 UT (orbit 785). It shows surface manifestations of a large number of nonlinear internal wave trains generated by the action of the tide at the continental shelf break.

Bragg waves and therefore we can apply a Wentzel-Kramers-Brillouin-type theory to describe their interaction. In this theory the transport equation describing the variation of the spectral energy density of short waves in a slowly varying current field is the action balance or radiation balance equation[21-23,27]

$$\frac{\mathrm{d}N}{\mathrm{d}t}=\left(\frac{\partial}{\partial t}+\dot{\boldsymbol{x}}\cdot\frac{\partial}{\partial \boldsymbol{x}}+\dot{\boldsymbol{k}}\cdot\frac{\partial}{\partial \boldsymbol{k}}\right)N=S(\boldsymbol{x},\boldsymbol{k},t) \qquad (2)$$

where $N(\boldsymbol{x},\boldsymbol{k},t)=E(\boldsymbol{x},\boldsymbol{k},t)/\omega'$ is the action spectrum, $E(\boldsymbol{x},\boldsymbol{k},t)$ the wave spectrum, ω' the intrinsic frequency of the wave in a reference system which is locally at rest, $\boldsymbol{x}$ the space variable, $\boldsymbol{k}$ the wavenumber and $S(\boldsymbol{x},\boldsymbol{k},t)$ a source function. The waves propagate along trajectories in four-dimensional phase space, given by the ray equations, $\dot{\boldsymbol{x}}=\partial\omega/\partial\boldsymbol{k}$ and $\dot{\boldsymbol{k}}=-\partial\omega/\partial\boldsymbol{x}$, where $\omega(\boldsymbol{x},\boldsymbol{k},t)=\omega'(\boldsymbol{k})+\boldsymbol{k}\cdot\boldsymbol{U}(\boldsymbol{x},t)$ denotes the wave frequency in the moving medium with variable velocity $\boldsymbol{U}(\boldsymbol{x},t)$.

We assume that the variable surface current leads to only small deviations of the action density from equilibrium and therefore write the action density, N, and the surface current, $\boldsymbol{U}$, as sums of a constant equilibrium term and a time-dependent perturbation term, $N(\boldsymbol{x},\boldsymbol{k},t)=N_0(\boldsymbol{k})+\delta N(\boldsymbol{x},\boldsymbol{k},t)$ and $\boldsymbol{U}(\boldsymbol{x},t)=\boldsymbol{U}_0+\delta\boldsymbol{U}(\boldsymbol{x},t)$. Furthermore, for small perturbations we can approximate the source term S by a diagonal operator, $S(\boldsymbol{x},\boldsymbol{k},t)=-\mu\delta N(\boldsymbol{x},\boldsymbol{k},t)$, where μ is a parameter with dimension (time)$^{-1}$, called relaxation rate, and $\tau_r=\mu^{-1}$ is the relaxation time, a system constant determined by the combined effects of wind excitation, energy transfer to other waves caused by conservative resonant wave-wave interaction and energy loss through dissipative processes such as wave breaking. No direct measurements of τ_r in the open ocean exist, but theory predicts that it is of the order of 10-100 wave periods. Applied to Seasat-SAR Bragg waves, this means that τ_r should lie in the range 4.7-47 s. Inserting the above equation for N, $\boldsymbol{U}$, S,$\dot{\boldsymbol{x}}$ and $\dot{\boldsymbol{k}}$ into equation (2) and retaining only first-order terms gives

$$\left(\frac{\partial}{\partial t}+(\boldsymbol{c}_g+\boldsymbol{U}_0)\cdot\frac{\partial}{\partial \boldsymbol{x}}+\mu\right)\delta N=\boldsymbol{k}\cdot\frac{\partial \boldsymbol{U}}{\partial \boldsymbol{x}}\cdot\frac{\partial N_0}{\partial \boldsymbol{k}} \qquad (3)$$

where $\boldsymbol{c}_g=\partial\omega'/\partial\boldsymbol{k}$ is the group velocity. The time scales of the three terms on the left-hand side are the local time, τ, the advection time, τ_a, and the relaxation time, τ_r; $\tau=\Omega^{-1}$, where Ω is the radian frequency of the internal waves, and $\tau_a=|(\boldsymbol{c}_g+\boldsymbol{U}_0)\cdot\boldsymbol{K}|^{-1}$, where $\boldsymbol{K}$ denotes the wave vector of the internal wave. In general, both τ and τ_a are $\gg 1$ min; consequently, the first two terms on the left-hand side of equation (3) should be much smaller than the third, the relaxation term, which alone is retained.

Specializing equation (3) to describe the modulation of Bragg waves, defining the projection of the antenna axis on the horizontal plane as x axis, we obtain

$$\frac{\delta\sigma}{\sigma_0}=\frac{\delta N}{N_0}=\frac{\delta E}{E_0}=-(4+\gamma)\tau_r\frac{\partial U_x}{\partial x} \qquad (4)$$

Here $\delta\sigma=\sigma-\sigma_0$ denotes the deviation of the normalized radar cross-section, σ, from its mean value σ_0; γ is the ratio between the group and phase velocity of the Bragg waves ($\gamma=0.5$ for gravity waves). In deriving equation (4) we have assumed that $E\propto|\boldsymbol{k}|^{-4}$, that is, E has the form of the Phillips equilibrium spectrum[15], and that σ is related to E through equation (1). Equation (4) is our principal result here, showing that the cross-section modulation caused by internal waves is proportional to the product of the surface current gradient in the look-direction of the antenna and the relaxation time, τ_r.

An analysis of Seasat-SAR imagery of underwater sandbanks in the Southern Bight of the North Sea[27] has estimated the relaxation time of the Bragg waves; for a wind speed of 4 m s^{-1},

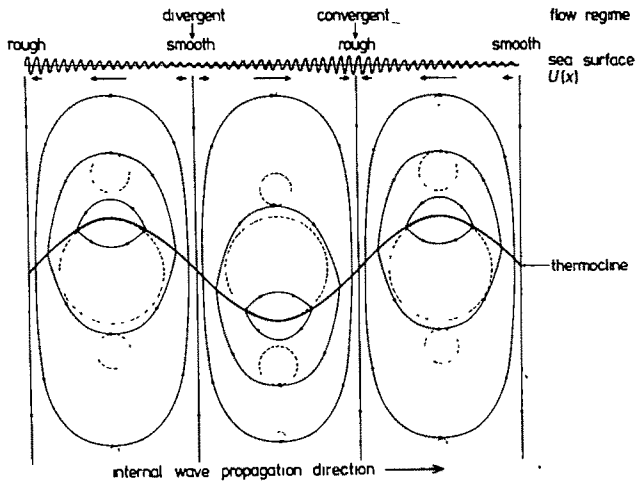

Fig. 2 Schematic plot of streamlines and particle velocities associated with a linear internal wave propagating along a sharp thermocline (adopted from ref. 28). The short-scale surface roughness is modulated by the surface current associated with the internal waves.

it is ~30–40 s, corresponding to 60–80 wave periods. This value of τ_r seems large, but is still within the predicted range.

Note that if we wanted to describe the cross-section modulation by long surface waves, equation (4) would not be applicable. In this case the corresponding equation would be

$$\frac{\delta\sigma}{\partial_0} = \frac{\delta N}{N_0} = \frac{\delta E}{E_0} = -\left(\frac{4+\gamma}{\hat{\omega}}\right)\frac{\partial U_x}{\partial x} \qquad (5)$$

where $\hat{\omega}$ denotes the radian frequency of the long surface wave and U the associated orbital velocity. Note that in equation (5) the factor in parenthesis is typically a factor of 10–20 larger than the corresponding factor in equation (4). The other factor in equation (4), the horizontal current gradient (or strain rate), $\partial U_x/\partial x$, can be calculated from internal wave theory[15].

Figure 2 shows the streamlines and water-particle orbits in a linear internal wave travelling from left to right at the boundary of two water layers of different density (thermocline). The internal waves cause almost no elevation of the surface and are associated with a spatially and temporally varying surface current field which interacts with the surface waves, giving rise to the surface-roughness modulation depicted in Fig. 2.

In the case of a nonlinear internal wave packet travelling from left to right, the vertical displacement of the thermocline and the roughness pattern have qualitatively the form shown in Fig. 3. The roughness pattern consists of pairs of adjacent very rough and smooth streaks separated by broad areas with a mean local roughness; the associated radar image therefore consists of pairs of adjacent bright and dark bands on a uniform background.

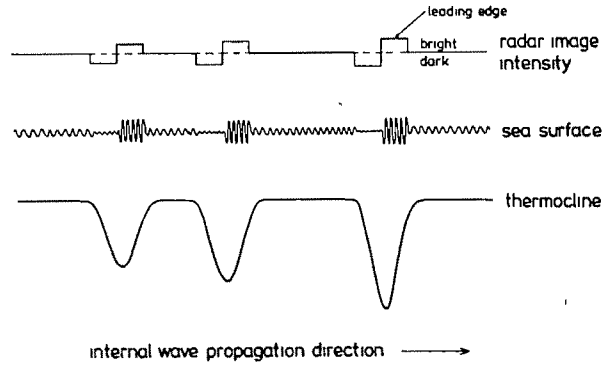

Fig. 3 Schematic plot of the thermocline displacement, the surface roughness modulation and the radar image intensity modulation associated with a nonlinear internal wave packet travelling along a shallow thermocline. The leading edge of the wave packet is associated with increased surface roughness leading to a bright band in the radar image.

The leading edge of the nonlinear internal wave train is associated with a convergence zone[29], giving rise to a bright band in the radar image.

Typical values for the strain rate of linear internal waves in coastal regions are $10^{-3}\,s^{-1}$ (ref. 7), but can be more than an order of magnitude greater for strongly nonlinear waves. If a surface current gradient of $10^{-3}\,s^{-1}$ and a relaxation time of $\tau_r = \mu^{-1} = 40$ s is inserted into equation (4), then one obtains for the modulation depth, $\delta\sigma/\sigma_0 \sim 0.2$, values commonly observed in radar imagery of internal waves. Although the surface current gradient associated with internal waves is typically an order of magnitude smaller than that associated with long surface waves, the modulation depth of internal waves can nevertheless be stronger than that of long surface waves, because the factor by which the surface current gradient is multiplied is an order of magnitude greater for internal waves (compare equations (4) and (5)).

The physical explanation for the large cross-section modulations obtained with our theory is as follows. In the case of internal waves, the straining exerted on the short-wave system by the current gradient is balanced by the relaxation of the wave system. This balance is different from the one active in the modulation of short waves by long surface waves, where the straining is balanced mainly by the temporal variation of the orbital velocity. Typically, the time scale of the relaxation (the relaxation time) is an order of magnitude greater than that of the orbital velocity, given by $\hat{\omega}^{-1}$. Thus in the case of short-wave modulation by internal waves, the straining can act sufficiently long on the short-wave system for a strong modulation to build up. Indeed the modulation is only limited by the relaxation time, which is a parameter describing how much disequilibrium the short-wave system can endure while subject to strain by a variable current.

Martian atmospheric carbon dioxide and weathering products in SNC meteorites

R. H. Carr, M. M. Grady, I. P. Wright & C. T. Pillinger

Planetary Sciences Unit, Department of Earth Sciences,
The Open University, Walton Hall, Milton Keynes MK7 6AA, UK

SNC meteorites—four shergottites, three nakhlites and Chassigny—are postulated to have originated on Mars[1]. Their late crystallization ages (<1,300 Myr compared with 4,600 Myr for other igneous meteorites) and the presence, in shock-produced glass in EETA79001, of noble gas[2] and nitrogen[3] components resembling the martian atmosphere provide evidence for such a provenance. If this interpretation is correct then carbon dioxide, by far the most abundant constituent of the martian atmosphere[4], should also be present. The stepped combustions described here show that most of the carbon present in the samples can be ascribed to terrestrial contamination. EETA79001, however, contains 4.6 p.p.m. of an isotopically distinct component enriched in ^{13}C ($\delta^{13}C = +36‰$), whereas high-temperature carbon of inferred igneous origin in this meteorite and other SNCs has a $\delta^{13}C$ value of about −30‰. The $^{12}C/^{13}C$ ratio of the isotopically heavy component is within the error limits of Viking measurements[4] in the martian atmosphere and, thus, strengthens the case for a planetary origin. Another carbon-containing species, believed to be carbonate, has been found in Nakhla ($\delta^{13}C$ = between +12 and +24‰) and may be a product of atmospheric weathering on Mars.

Analyses of SNC meteorites were performed using a stepped combustion technique, similar to that of Swart *et al.*[5]; isotope measurements were made using a high-sensitivity static mass spectrometer capable of determining $\delta^{13}C$ values to a precision of ±3‰ or better on samples as small as 6×10^{-9} g carbon in the form of carbon dioxide (R.H.C., I.P.W., A. W. Joines and C.T.P., in preparation). $(\delta^{13}C(‰) = (R_{sam}/R_{std} - 1) \times 1{,}000$, where $R = {}^{13}C/{}^{12}C$ and $R_{std} = 0.0112372$.)

Bulk carbon contents and isotope compositions for all the meteorites obtained by summation of data from individual extraction steps are plotted in Fig. 1*a*. The total amounts of carbon present in the meteorites define three groups: (1) those recovered from the Antarctic ice cap, ignoring for the moment lithology B of EETA79001, have the lowest carbon contents (<150 p.p.m.); (2) Governador Valadares and Lafayette (>750 p.p.m. C) were found after an unknown length of time on Earth; (3) samples with intermediate carbon contents are all meteorites observed to fall and recovered soon afterwards. This pattern, which reflects the known contamination hazards[6,7] of the terrestrial environment, suggests that the carbon content of SNC meteorites is dominated by biological organic matter produced on Earth. Such a conclusion is supported by the bulk $\delta^{13}C$ data which, with the exception of Nakhla, lie in the range −20 to −30‰. Lithology B of EETA79001 was processed in a slightly different way in our laboratory and may have acquired much of its relatively large carbon content as contamination there rather than in the natural environment before collection.

The above data demonstrate the ubiquity of contamination and exemplify the difficulties involved in obtaining useful carbon isotope information from samples with a low indigenous carbon content. The problems of contamination can be overcome to some extent, however, by consideration of the carbon released during high-temperature steps of the stepped combustion. Although most terrestrial organics burn at low temperatures[5,8], it is probably not possible to choose a unique temperature for differentiating between contamination and indigenous carbon. We have chosen to consider the carbon which combusts above 600 °C. Figure 1*b* plots the summed abundance of carbon extracted above 600 °C against isotope composition. Chassigny occupies a unique position in the plot. The shergottites, with the exception of one sample of Shergotty, and the nakhlites, which are closely grouped, appear to define a two-component mixing trend, with one component an isotopically heavy species

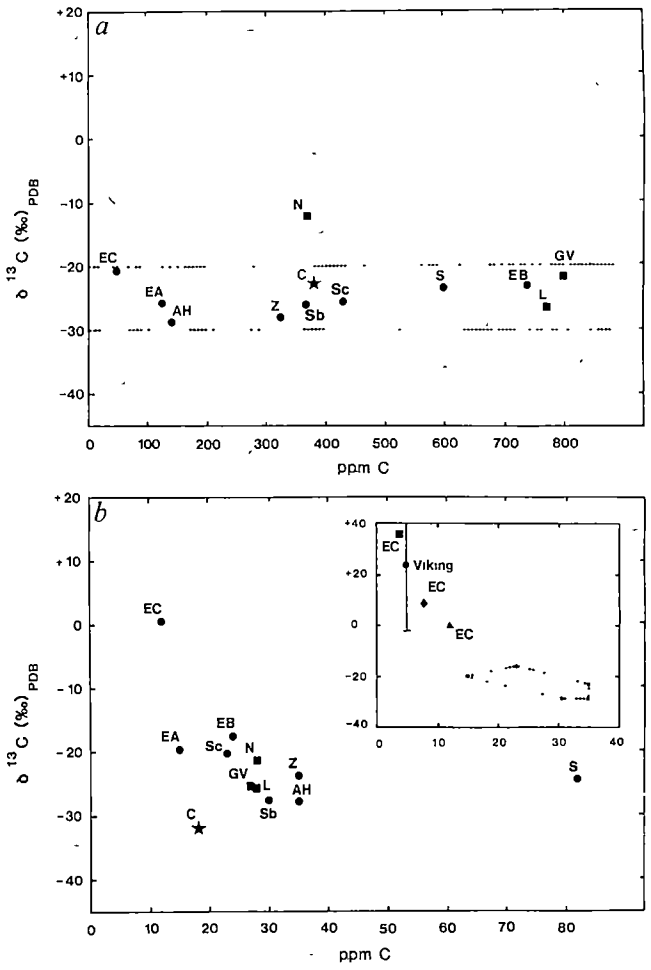

Fig. 1 *a*, Calculated bulk carbon contents and isotope compositions for samples of the shergottites (●), the nakhlites (■) and the chassignite (★). *b*, Data from >600 °C extraction steps. Inset, comparison of the SNC dataset with Viking atmospheric carbon dioxide measurements: ▲, 600–1,200 °C steps measured; ◆, 900–1,200 °C steps measured, ■, trapped atmospheric component calculated. Allan Hills 77005 (AH), Chassigny (C), Elephant Moraine 79001-lithologies A, B and C (EA, EB, EC); Governador Valadares (GV); Lafayette (L); Nakhla (N); three Shergotty samples (S, Sb, Sc) and Zagami (Z)

most easily discernible in EETA79001 lithology C. Note that about 60% of the excess carbon observed for the Shergotty sample(S) combusts at 700 °C with a $\delta^{13}C$ of −23‰, suggesting the presence of a third component.

The glass from EETA79001 is distinct from other samples studied, in that carbon released by combustion above 600 °C (Fig. 1*b*) is enriched in ^{13}C by ~20‰. Figure 2*a* shows the complete release profile for the glass; a similar profile for the host igneous material, lithology A, is shown in Fig. 2*b* for comparative purposes. The component which causes the glass (lithology C) to be enriched in ^{13}C above 600 °C is the carbon with positive $\delta^{13}C$ values released between 1,000 and 1,200 °C which is absent from the host rock.

Other authors[2,3] comparing samples of lithologies A and C of EETA79001 have noted the presence in the latter of noble gases and nitrogen with relative abundance and isotope compositions that match values measured for the martian atmosphere[4] and have accordingly argued for the existence of a trapped atmospheric component in the glass phase. The release temperatures for the proposed atmospheric components are >1,100 °C (ref. 2) and >800 °C (ref. 3) respectively. Although no isotopically heavy carbon is seen in the lithology A sample, some carbon is liberated between 900 and 1,200 °C. We take this to be indigenous carbon of igneous origin. This does not signify that we believe no terrestrial contaminants survive above

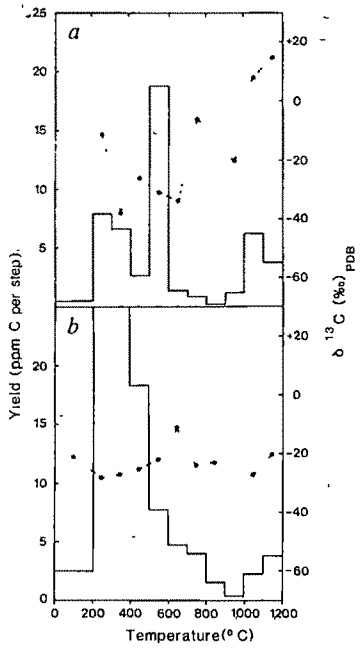

Fig. 2 Isotope composition and carbon release profile for stepped combustion of the Elephant Moraine shergottite 79001. *a*, Lithology C (glass); *b*, lithology A.

600 °C or, indeed, that indigenous components are not volatile at lower temperatures. Assuming this original carbon is completely retained during the process of shock melting, we calculate the difference between lithologies C and A (as done for nitrogen[3]) that is the trapped carbon component, to be 4.6 p.p.m. of carbon with an isotope composition of +36‰ (±10‰) ignoring any small contribution from spallogenic sources. The abundance of noble gases (and nitrogen) measured in different glass inclusions, assuming an atmospheric origin, suggest that 5 p.p.m. of trapped martian carbon dioxide ought to be present[2]. The agreement between predicted and measured abundance is extremely good. Likewise, the $^{13}C/^{12}C$ ratio corresponding to a $\delta^{13}C$ value of +36‰ is within the errors of the 'ground truth' measurements made by Viking spacecraft[4].

The inset to Fig. 1*b* shows the experimental and calculated data for EETA79001 lithology C and the atmospheric isotope composition at the predicted abundance. These points fall on the trend established from >600 °C carbon measurements and seem to support the two-component model proposed above with: (1) the heavy carbon species being atmospheric carbon dioxide; (2) the indigenous igneous carbon, by implication, having a $\delta^{13}C$ value of about −30‰; (3) shergottites and nakhlites belonging to a common provenance and having a related origin; and (4) the universally shocked shergottites being more likely to exhibit an atmospheric component trapped in glass. In relation to point (4), excess amounts of ^{40}Ar, interpreted as being from the martian atmosphere have been found in other shergottite samples[9] and we have previously pointed out the tendency for $\delta^{13}C$ values to rise at high temperatures for SNC meteorites[10]. A more convincing demonstration of the applicability of the two-component model requires separation and analyses of shock-produced glass from a variety of SNC specimens, although this may only be possible for ALHA77005.

Although not specifically related to the above discussion, other differences exist between the stepped combustion profiles of lithology A and C samples of EETA79001. A proportion of the total carbon (25%) is liberated below 500 °C for the glass; this is substantially less than for non-Antarctic meteorites and EETA79001 lithology A. The relatively high $\delta^{13}C$ value (−11‰) of the 200–300 °C extraction shows that this cannot be due entirely to biologically-produced organic contamination. Similar isotopically heavy carbon releases have been enountered with other Antarctic meteorite samples and it has been suggested that

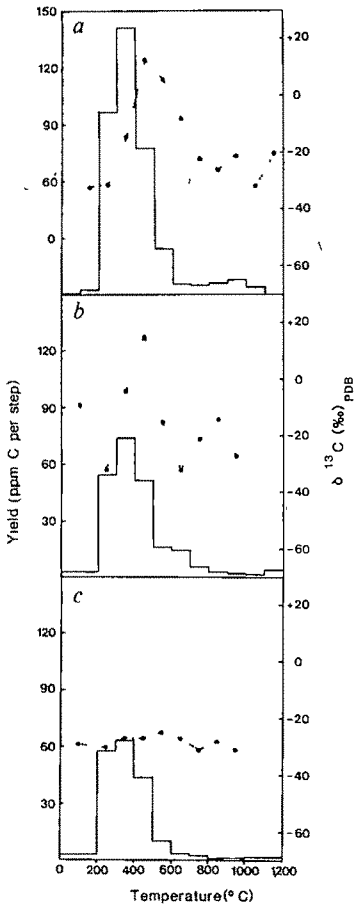

Fig. 3 Isotope composition and carbon release profiles for stepped heating: *a*, of Nakhla in oxygen; *b*, of Nakhla *in vacuo*; *c*, of the H_3PO_4 dissolution residue in oxygen.

a terrestrial weathering product may be responsible[5]. The component is presumably masked by more abundant isotopically light contamination in lithology A. Much more interesting is the large release of carbon with $\delta^{13}C = -31$‰ at 500–600 °C from lithology C but not lithology A. This component was also found for ALHA77005, another Antarctic shergottite. It may be connected with the excess of carbon in Shergotty because a larger sample of bulk Shergotty studied by Fallick *et al.*[11], also liberated substantial amounts of carbon at 600–700 °C with $\delta^{13}C = -28$‰. The source of this carbon is unknown; however, it may be related to the presence of shock-altered minerals, increased abundance in a large Shergotty specimen being consistent with a chance sampling of such material.

Nakhla has a bulk $\delta^{13}C$ of −12‰ quite distinct from all other SNC meteorites (Fig. 1*a*). This bulk isotope composition, first recognized by Fallick *et al.*[11], is dictated by the presence of a component which is volatile at <600 °C since Nakhla plots along with the other nakhlites in Fig. 1*b*. The individual steps of the stepped combusion (Fig. 3*a*) and a stepped pyrolysis (Fig. 3*b*) demonstrate that the component is, in fact, decomposed in the temperature range 300–500 °C, either with or without oxygen being present, to give carbon dioxide with a $\delta^{13}C$ rising to +15‰ in both cases. Treatment of powdered Nakhla with either hydrochloric or orthophosphoric acid removes the isotopically heavy carbon component as is shown by the stepped combustion of the residue of H_3PO_4 treatment (Fig. 3*c*). During the orthophosphoric acid reaction, carbon dioxide was collected in two steps and taken for isotope measurement. The results, given in Table 1, confirm that this gas contains carbon which is isotopically heavy, having $\delta^{13}C$ values up to +12‰. The thermal stability and chemical properties of the isotopically heavy carbon component in Nakhla are consistent with it being a carbonate present at ~0.02 wt % level. The particularly extended reaction time

†Mass scans of these samples indicated the presence of organic species, which may have interfered with the isotope ratio measurements of the CO_2. Hence, the determined $\delta^{13}C$ values may show an apparent enrichment in ^{13}C above the true value.

recognized during H_3PO_4 treatment of a sample of a second stone from the Nakhla meteorite shower (BM1911, 360) suggests that the species is not calcite but more probably dolomite or an iron-containing carbonate. Neither of the other nakhlites show any evidence of a ^{13}C-rich component decomposing at between 300 and 500 °C, although this may be because of the release of relatively large amounts of organic material from these contaminated samples. During the stepped combustions of one sample of Shergotty and the Chassigny specimen, $\delta^{13}C$ values did increase to −12‰ and −18‰ respectively[10], but more work would be necessary to demonstrate the presence of carbonate.

A petrological investigation to confirm the presence of carbonate in Nakhla is required, but assuming that its existence is verified, the question which must be answered concerns its origin—terrestrial or martian? Terrestrial carbonates with $\delta^{13}C$ values higher than +10‰ are rare[12]. Terrestrially produced carbonates are a common feature of Antarctic weathering; all appear to have normal $\delta^{13}C$ values but such features are less conspicuous in non-Antarctic meteorites[5]. For martian carbonate to survive in Nakhla, the shock events involved in its ejection from the planet surface would presumably need to be such that temperatures did not rise to greater than 500 °C.

We have speculated that carbon dioxide in the martian atmosphere is enriched in ^{13}C relative to carbon of presumed igneous origin as present in the SNC meteorites. It may be coincidence, but recognition of enrichments of the same order for the carbonate may be circumstantial evidence for an origin by weathering in the martian environment, particularly as dolomite would be an expected product of gas-solid reaction of martian pyroxenes[13]. We note, too, that Nakhla contains iddingsite, an aqueous alteration product of olivine, which is believed to be preterrestrial in origin[14]. Unfortunately, the pyrolysis gas chromatograph-mass spectrometer experiment[15] carried out by Viking Landers, which might have been able to detect the decomposition products of carbonate and provide some isotope information was performed in such a way as to preclude such identification. It does not seem possible that the carbon dioxide trapped in EETA79001 is the relict of carbonate decomposed during shock heating, as such a route would be extremely unlikely to preserve the observed relative abundance to other atmospheric gases.

The existence of a trapped component of carbon dioxide in the correct abundance relative to noble gases and nitrogen and of an appropriate isotope composition to be of martian atmospheric origin strengthens the case that EETA79001 originated from our sister planet. The relationship between the martian atmospheric composition and data from EETA79001, other shergottites, and the nakhlites (inset in Fig. 1*b*) demonstrates that all these meteorites are related and presumably also derived from Mars. Likewise, demonstration of the existence of a carbonate mineral with a martian atmospheric composition would be direct evidence of the origin of Nakhla and its consorts from the planet.

We thank Dr S. O. Agrell, the British Museum (Natural History), the Antarctic Meteorite Working Group and Professor J. C. Laul for samples. This work was supported by the SERC.

A high-temperature high-resolution NMR study of ^{23}Na, ^{27}Al and ^{29}Si in molten silicates

Molecular and atomic motions over longer distances, and with much lower frequencies than interatomic vibrations, have a major role in the energetic and dynamic properties of highly structured liquids such as molten aluminosilicates. Rearrangement with increasing temperature of the polymerized anionic network (composed of linked SiO_4^{4-} and AlO_4^{5-} tetrahedra) controls viscosity and influences thermal expansion and configurational heat capacity[1,2]. Diffusive motion of network modifying cations (such as Na^+) through the structure allows electrical conductivity and probably also affects entropy. To study such motion directly and to compare liquid and glass structure, we have developed a novel high-temperature high-resolution NMR apparatus. We report here the first data on ^{23}Na, ^{27}Al, and ^{29}Si in liquids in the system $Na_2O/Al_2O_3/SiO_2$ at temperatures to about 1,300 °C. Observed changes in NMR resonant frequencies (chemical shifts) give information on the effects of composition on local structure. Line shapes and widths, and relaxation time measurements, reveal details of the dynamics and of the transition from liquid to glass.

The apparatus developed for high-temperature liquid-state NMR will be described in detail elsewhere. A sample in a 1-cm diameter boron nitride capsule is rapidly shuttled 15 cm between a furnace and a room-temperature radio frequency NMR coil, spending 10 s in the former and ~0.5 s in the latter during each cycle, during which data from a single free-induction decay (FID) is recorded. Both the probe and the furnace are mounted in a 4.2 T superconducting magnet. Sample temperatures could not be measured during actual NMR experiments, but calibration runs indicate that reported values are accurate to within about 30 °C.

Samples were prepared from reagent grade oxides and carbonates. For all ^{29}Si NMR, 95% enriched $^{29}SiO_2$ was used. Analyses of unenriched samples after the NMR runs showed that by the end of runs of 6–12 h, Na_2O contents were reduced by 5–20% of the amount present. B_2O_3 contents became as high as 4 wt%.

Measurements were made with a home-built Fourier-transform NMR spectrometer, with 90° pulse lengths of 39 μs for ^{23}Na and ^{27}Al and 45 μs for ^{29}Si. Data from 40 FIDs were averaged per spectrum for ^{23}Na, and up to 400 for ^{27}Al and ^{29}Si.

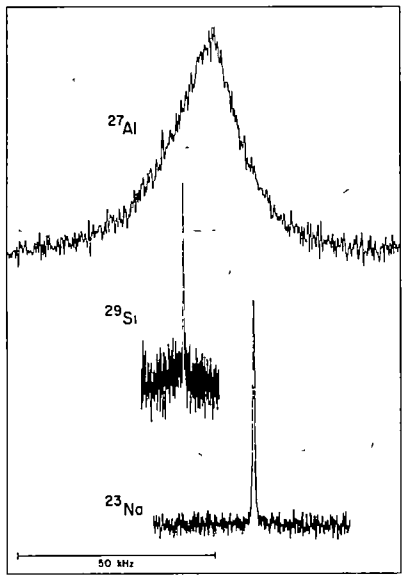

Fig. 1 Typical NMR spectra for molten silicates. Data are for $NaAlSi_2O_6$ at about 1,300 °C Relative location of the spectra is arbitrary, but all have the same frequency scale.

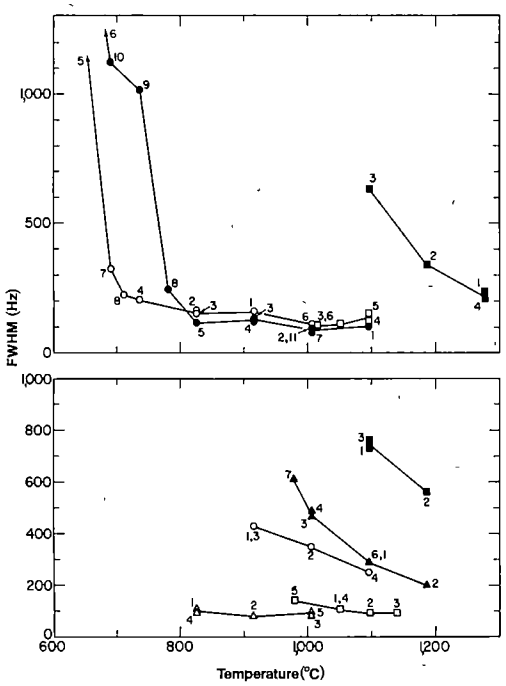

Fig. 2 Linewidths for ^{29}Si (top) and ^{23}Na (bottom) liquid spectra, as a function of temperature. Symbols indicate nominal composition. ●, $Na_2Si_4O_9$; ○, $Na_2Si_2O_5$; ■, $NaAlSi_2O_6$; □, Na_2SiO_3, ▲, 'R15' (see text), △, NaCl. Numbers show the order in which measurements were made and indicate reproducibility.

Relaxation time measurements were made by standard pulse techniques, using compensated π pulse sequences[3]. Chemical shifts are referenced to saturated aqueous NaCl (about 6.5 M), $[Al(H_2O)_6]^{3+}$, and TMS, all at room temperature

Typical spectra are shown in Fig. 1, linewidths in Fig. 2 and chemical shifts in Fig. 3. The chemical shift measurements were made at the beginning of runs when compositions were presumed to be close to nominal.

As shown in Fig. 3, ^{29}Si chemical shifts (δ) change systematically with composition, as expected from data on glassy and crystalline solids[4–7]. Liquids that are more polymerized (higher mean Q^n number, where n is the number of other AlO_4 or SiO_4 units bound to a given SiO_4 tetrahedron) have more negative δ

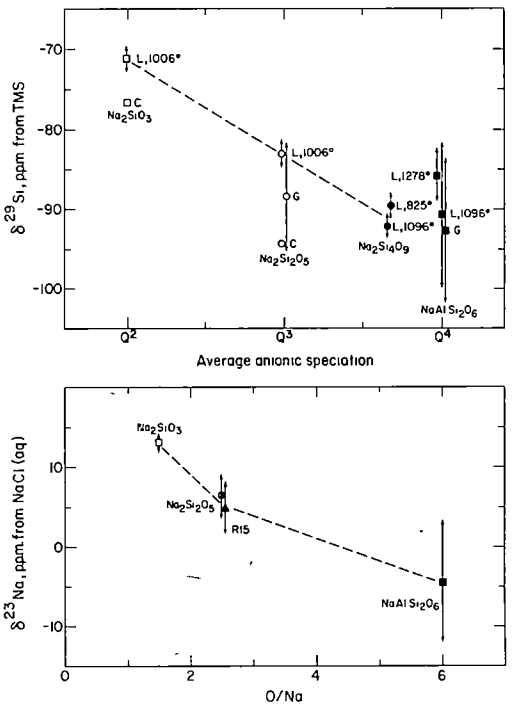

Fig. 3 Chemical shifts in silicates. Symbols as in Fig. 2, with L indicating liquid (at temperatures shown), C, crystalline solid, and G, glass (the latter two at room temperature). Arrows indicate linewidth, not errors Q^n is the average speciation of the liquid, indicating n other $(Si, Al)O_4$ tetrahedral structural groups attached to a given group.

values, showing that ^{29}Si nuclei in tetrahedral sites with greater numbers of surrounding SiO_4 tetrahedra are more chemically shielded Substitution of Al for some of the Si reduces this shielding, as shown for $NaAlSi_2O_6$ liquid and glass. Silicon chemical shifts in the liquids are systematically less negative (less shielding) than in the corresponding glasses and crystals.

Sodium chemical shifts in liquid silicates seem to have a simpler variation with composition. In all four silicate samples studied, $\delta(^{23}Na)$ is well correlated with the ratio of the number of oxygen to sodium atoms, independent of polymerization state or the Al/Si ratio. Crystalline $NaAlSi_3O_8$ (−7.7 p.p.m.)[8] falls very close to the trend for the liquids, when referenced to the same standard[9]. Our value of 6.8 p.p.m. for $\delta(^{23}Na)$ in molten NaCl agrees well with data for the solid (6.7 p.p.m.)[8].

Spectra for ^{27}Al in samples $NaAlSi_2O_6$ and R15 (Na_2O: 35, Al_2O_3: 15, SiO_2: 50 mol%) each contain only a single very broad feature (about 20 kHz wide), centred at ~29 ± 20 p.p.m. The breadth of the peaks makes it difficult to draw conclusions about Al coordination in the liquids[10].

Observed linewidths (FWHM) at the highest temperatures studied for both ^{23}Na and ^{29}Si are quite narrow (100–200 Hz, or 2–5 p.p.m.), with symmetrical lorentzian line shapes. Direct measurements of T_2 for ^{23}Na and ^{29}Si indicate that, for linewidths greater than about 200 Hz, the 'intrinsic' contribution from relaxation of spins dominates, and that, therefore, $FWHM \approx 1/(\pi T_2)$, where T_2 is the spin-spin relaxation time[11]. Smaller linewidths are dominated by instrumental effects. A few T_1 (spin-lattice) relaxation times for ^{23}Na show that $T_1 \approx T_2$ in Na_2O/SiO_2 liquids, but that $T_1 > T_2$ in the more viscous aluminosilicate liquids. Narrow high-temperature linewidths for ^{29}Si indicate that silicate species move rapidly enough to average out the effects of chemical shielding anisotropy (at least 3.5 kHz)[6], while ^{23}Na motion in the binary liquids is probably at least as fast as the NMR resonant frequency of the nucleus (or, the Larmor frequency, 47.3 MHz). For both nuclei, the FWHM increases (T_2 decreases) dramatically with decreasing temperature, as the motion that induces relaxation is 'frozen out'. For ^{29}Si, the lowest temperature at which data were

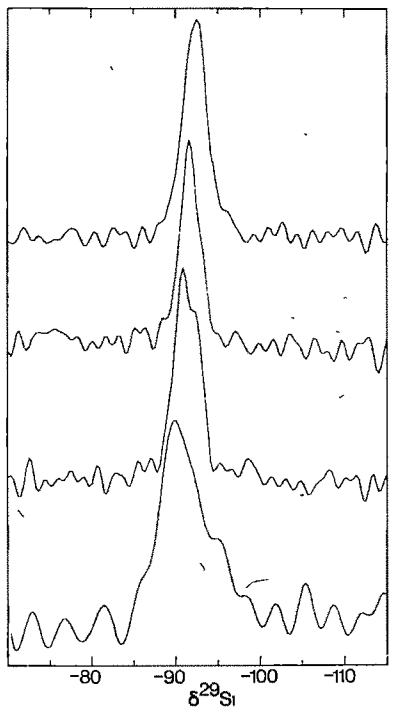

Fig. 4 ^{29}Si spectra for $Na_2Si_4O_9$ liquid at 1,096 °C (top), 1,006 °C, 915 °C, and 779 °C (bottom), normalized to the same peak height. $\delta(^{29}Si)$ is in p.p.m. Note the development of a shoulder on the central peak as the temperature is lowered.

collected was that at which the spectrum became extremely broad and 'solid-like'. In $Na_2Si_2O_5$, this was probably the result of crystallization. The $NaAlSi_2O_6$ sample, however, was recovered as a glass, indicating that the 'glass transition' with respect to molecular motion faster than 3.5 kHz was observed. Not surprisingly, more-polymerized more-viscous liquids have wider NMR lines (shorter T_2 values) at a given temperature (Fig. 2).

The very broad bands observed for ^{27}Al indicate that even though these samples were liquid, quadrupole coupling was strong enough to cause the nuclei to relax very rapidly ($T_2 \approx 20$ μs).

For Na and Si in a series of silicate liquids at high temperatures, molecular motion has a significant component at or above the kHz frequency range. At lower temperatures, the loss of this motion can be observed. The nature of this motion remains a key problem. In a discussion of liquid heat capacities, Stebbins *et al.*[2] emphasized the possibilities of rotational and translational motion of anionic molecular groups, but pointed out that mechanisms involving the breaking of strong Si–O or Al–O bonds must become important in more polymerized liquids.

Raman and magic-angle spinning NMR spectra of glasses[7,12] show that a range of silicate (Q^n) species, with a different range of chemical shifts for each value of n, make up the anionic structure of these materials. Observation of only one narrow ^{29}Si NMR line in the liquid suggests that these species chemically-exchange rapidly with respect to the typical separation in resonant frequency between the species (10–15 p.p.m. or 300–500 Hz). Only a time-averaged spectrum is observed. In aqueous silicate solutions, similar effects are seen, until temperature is lowered enough and exchange rates become slow enough to allow peak splitting to occur[13]. The development of shoulders on ^{29}Si peaks in some silicate melt spectra may suggest a similar slowing of reaction rates (Fig. 4). Structural rearrangement that includes the exchange of Q^n species involves breaking and reforming of Si–O bonds and apparently occurs even in a rather depolymerized liquid such as Na_2SiO_3. The relative contribution of this type of motion to the overall energetics of the liquid remains unknown.

The preliminary results presented here thus show that NMR spectroscopy on silicate liquids can help to identify what types of molecular motion occur, can begin to quantify the rates of such motions, and demonstrates the effects of composition. These and further data should prove useful in the understanding of both the thermodynamic properties of melts and the closely related processes of flow and diffusion.
